They are very large mononuclears, 15 to 30μ in diameter, with basophilic non-granular cytoplasm, and are probably macrophages of endothelial origin. They are possibly identical with the cells described by Jurgens, Dutcher, and Bahr in the stools of bacillary dysentery some years ago.

The cytoplasm, if not too degenerated, contains numerous vacuoles in which there may be entire polymorphonuclear leucocytes, lymphocytes, red cells, or their fragments, and bacteria, more or less digested. Curiously enough, the ingested leucocytes are much less degenerated than their hosts. By Achard's method of eosin staining these large cells can usually be demonstrated to be dead. In others, as a result presumably of more advanced degeneration, the cytoplasm, instead of being granular and vacuolated, is swollen, hyaline, transparent, and apparently in a state of hydropic degeneration; it stains very poorly or not at all with iron-alum-hæmatoxylin.

The degenerative process begins early in the cytoplasm, which first becomes granular, then vacuolated, and finally hyaline. It may show dots or granules, which are greenish when examined in the fresh state and intensely black when stained with iron-hæmatoxylin.

These are probably fragments extruded from the pyknotic nuclei. In fresh specimens these dots are frequently seen to exhibit distinct Brownian movements and are apt to be mistaken for bacteria or other débris which the cell has ingested. Coincidently with the cytoplasm the nuclei begin to show very definite karyorrhectic and karyolytic changes, both in fresh and stained specimens.

The nucleus first becomes swollen, then granular; finally its centre becomes transparent and the chromatin is aggregated under the nuclear membrane, leaving the centre bare. (In other cases pyknosis may be the only change, as seen in the stained specimens.) The nucleus then bursts, and the granules resulting from this action appear as a scattered line of irregular dots—green in the fresh and black in the stained specimens—which are apparently caught in the periplast, all that remains of the cytoplasm.

Later these dots disappear, and the cell is represented only by the periplast, which is usually regularly circular. (Fig. 15.) These cells, as their suggested origin implies, possess certain feeble powers of amœboid movement, a characteristic which is liable to entrap the unwary.

Fig. 18 shows one of these macrophages (fixed and stained by the Schaudinn-Heidenhain method), which suggests that it has been caught in the act of throwing out a pseudopodium.

These endothelial macrophages resemble resting or dead amœbæ most closely when they show the aggregation of chromatin granules scattered around the periphery of the nucleus; then one sees a large round cell, vacuolated and containing ingested cells, with a nucleus which exhibits the "ringing" so characteristic of the nucleus of amœbæ. The fact, however, that the nucleus in a degenerating amœba is the last structure to disappear may be of some guidance in differentiation.

Similar degenerative changes to those mentioned occur in the leucocytes and also to a less extent in the mucosal cells.

Fatty degeneration is always present in the cells composing the exudate in bacillary dysentery. In the very early stages this change is very slight and the intracorpuscular globules present in leucocytes and desquamated mucosal cells appear as dust-like red granules when examined under the immersion lens, and a Sudan III. in alcoholic solution is run in under the coverslip.

Later these globules become larger and larger, until in the advanced cases the greater part of the cell body is filled with them. In some we have even seen the leucocytes distended with large red globules crammed together inside the periplast like potatoes in a sack. This condition is best seen in the liquid green pea-soup type of stool, without obvious muco-pus or blood, characteristic of advanced subacute or chronic bacillary dysentery. (Fig. 10.)

Another point to strike the observer in cases of *acute* bacillary dysentery is the extraordinarily small number of bacteria present; the film, in fact, looks more as though it had been taken from the pus of a streptococcal abscess than from a stool. (Contrast Figs. 3 and 12.)

To sum up the characteristics of a bacillary stool:—

1. Abundance of cellular exudate, mostly polymorphonuclear.
2. Preponderance of polymorphonuclears over mononuclears.
3. Evidence of toxic necrosis of cells, the degenerative changes occurring early in all parts of the cell, including the nucleus. This degeneration may go so far as to leave only the circular periplast of the cytoplasm, thus constituting the "ghost-cell," the presence of which in any quantity is very typical of bacillary infection.
4. Evidence of phenomena characteristic of intense inflammatory reaction to microbic infection.

Results of Cultural and Cyto-diagnostic Methods.

The cultural method of diagnosing bacillary dysentery is of value only when positive results are obtained.

It is, at best, a difficult operation—how difficult in all but the early acute cases only those who have had years of experience at this work fully appreciate. It is slow, laborious, uses up an enormous amount of glass-ware and medium, and necessitates a fully equipped laboratory with a well-trained staff. All these difficulties are multiplied under active service conditions, and we have no hesitation in saying that the experience of this campaign has shown it to be a complete failure, alike for statistical and clinical purposes, in that results reach the clinician too late to be of any guidance to him in his treatment.

We contend that our method of cyto-diagnosis is not only much more rapid and less laborious, but also that statistics based on it give a much truer idea of the incidence of bacillary infection than do any that are based on the isolation of dysentery bacilli—at least, under active service conditions.

A study of the various reports issued periodically by the field laboratories shows how far their return of positive findings falls below the real figure of bacillary cases. In one instance this represented only 7 per cent. of "blood and mucus" cases in which an expert protozoologist could find no amœbæ. The bacteriologist in charge at the time was a man of exceptional ability and long experience in this particular subject.

Appended are the figures of "cases of dysentery and suspected dysentery" for all the laboratories of Egypt—including those at the various bases under the direction of experts working under optimum conditions—during the first quarter of 1917.

1. Total number of cases examined	4037
2. Number showing blood and mucus	1127
3. Number of cases microscopically examined	3818
4. Dysenteric amœbic findings	300
5. Number of cases bacteriologically examined	3094
6. Dysenteric bacilli, typical and atypical, isolated	475

No. 6 gives 15·3 per cent. of No. 5.

Even if the whole of No. 4 be subtracted from No. 2 the percentage of No. 6 to No. 2 is only 57·4. Even this is too high a figure, as cysts are included in No. 4, and such stools usually do not contain blood and mucus. Further, no account is taken of mixed infections.

Mutability of Organisms.

Again, the cyto-diagnostic method has the further advantage of obviating a difficulty which recent experience has shown to beset the cultural method of diagnosing bacillary dysentery.

We refer to the doubt often present in the bacteriologist's mind as to whether a given organism which he has isolated is to be regarded or not as the actual cause of the disease. There is no doubt that the group of bacilli capable of causing dysenteric infection is a very large one, with much more elastic bounds than it has hitherto been customary to allot to it. This applies particularly to the so-called "mannite-fermenting group," the membership of which has of late years been expanded to admit a host of new candidates, all of which show a certain relationship in their serological and biochemical reactions to the classical Flexner-Y types.

The bacteriological work of the present campaign, while adding to our knowledge, has at the same time added vastly to our confusion in this respect.

Almost weekly a new type of bacillus—non-motile, Gram-negative, anaerogenic, non-lactose-fermenting—has turned up on our plates, each new type showing in infinite gradation affinities with, and divergence from, the classical in its bearing towards recognised agglutinating sera and fermentation of sugars. For instance, to take only two examples from opposite ends of the scale, we have on several occasions isolated a bacillus having all the bio-chemical and cultural characters of a typical *B. Shiga*, but showing no agglutination whatever with any Shiga-agglutinating serum at our disposal.

One such strain—isolated from one of us after a mild attack of dysentery—was as virulent when tested in rabbits as any type of *B. Shiga* in our possession.

Another bacillus was agglutinated up to 1:2000 by Y-serum from the Lister Institute, though not by normal serum, Shiga or typhoid serum in low dilution; yet this strain—the purity of which was tested by replating—fermented every sugar on which we tried it. It produced permanent acidity, but no clot, in milk.

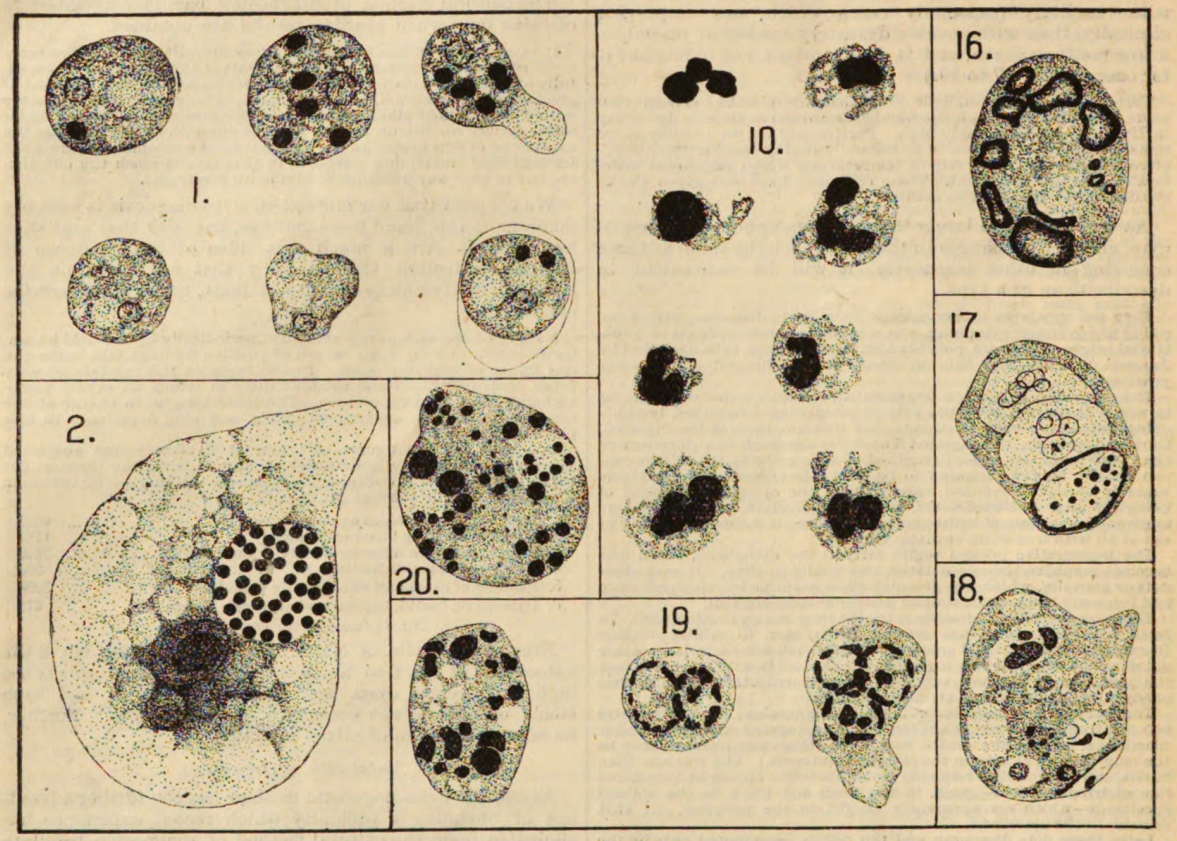
We may add here that the results of bacteriological investigation of a large series of cases of bacillary dysentery in the Central Laboratory, Alexandria, fully confirm such statements.

With all diffidence we hazard the suggestion that all pathogenic bacteria having their habitat in the intestine are actually or potentially mutable.** Apart from the facts bearing on mutability of the organisms of the enterica and dysentery families, we feel tempted in this connexion to quote others of a similar nature, relating to this phenomenon.

Thus, Bordet has shown that his *B. pertussis* could be changed by repeated subculture into an organism having entirely distinct cultural and agglutinative reactions.

** *Cæteris paribus*, the more nearly the infecting bacillus approaches the classical type, the more severe is the course of the disease, and the more prompt the response to serum; and vice versa.

FÆCAL FILMS FROM CASES OF ACUTE AMŒBIC (1–11) AND BACILLARY DYSENTERY (12–20).



DESCRIPTIONS OF ILLUSTRATIONS.

1. *Amœbic Dysentery.*

FIG. 1.—Types of *Entamœba histolytica*. Stained Schaudinn-Heidenhain-Wenyon method. Zeiss 1/12, Oc. II.

FIG. 2.—*Entamœba coli* with degenerated and vacuolated cytoplasm and ingested bodies, parasites. Note the unaffected appearance of the nucleus. Drawn in black and white, but stained as follows: Schaudinn-Heidenhain (Wenyon's modification): Decolourised completely in acid alcohol —> ammonia alcohol, and 50 per cent. spirit, —> counterstained 12 hours in Borrel's blue 1 c.cm., Gauducheau's stain 4 c.cm., dist. water 5 c.cm. Washed in 50 per cent. alcohol, to which a little 1 : 5000 acetic acid was added —> 0·5 per cent. eosin in alcohol —> absolute alcohol —> differentiated in oil of cloves (controlled under microscope) —> xylol —> Canada balsam.

By this method nuclear chromatin is stained blue-black, neutrophile cytoplasm pink, red blood cells crimson. The advantage of this method over the original Schaudinn-Heidenhain is that the cells inclusions can be differentiated from fragments of chromatin, and the nuclei of leucocytes, from which the cytoplasm has been stripped, from red blood cells. (This method is referred to hereafter as "W" stain.)

From a case of amœbic dysentery. Zeiss 1/12, Oc. VIII.

FIG. 3 (original in colours, but reproduced in black and white).—Fæcal film from a case of acute amœbic dysentery. "W" stain. Zeiss 1/12, Oc. II. Note the preponderance of mononuclears, the mouse-eaten appearance of the cytoplasm, the stripping of the unaffected nuclei. An amœba is seen, showing the characteristic nucleus.

FIG. 4 (original in colours).—Fæcal film from a case of acute amœbic dysentery. Modified "W" stain. Zeiss 1/12, Oc. II. An amœba containing red blood cells is seen, but the nucleus is not so obvious by this stain, as the iron hæmatoxylin was omitted.

FIG. 5.—Fæcal film from a fatal case of amœbic dysentery. This man died with symptoms of cholera, and vibrios (non-agglutinating) were present in the stools. Autopsy revealed multiform amœbic ulcers, thickly studding the large intestine from cæcum to rectum. The peritoneum was full of ascitic fluid; the spleen was hard and enormously enlarged; the liver in an advanced state of cirrhosis—a case of "Egyptian splenomegaly" (Ferguson).

FIG. 6 (original in colours).—Fresh fæcal film from a case of acute amœbic dysentery. Note the scantiness of cellular exudate. Zeiss 1/12, Oc. II.

FIG. 7.—Film from surface of colon—Schaudinn-Heidenhain-Wenyon stain. This was taken at autopsy from a case of advanced gangrenous amœbic dysentery such as is described in the text. Zeiss 1/12, Oc. II. Note the digested appearance of the cells.

FIGS. 8 and 9.—Fæcal films from fatal cases of amœbic dysentery—Schaudinn-Heidenhain-Wenyon stain. Zeiss 1/12, Comp. Oc. VI. Compare the macrophage containing a lymphocyte and red blood cells in Fig. 9 with the amœba in Fig. 8. Note that the nuclei of leucocytes and mucosal cells are unaffected, while the cytoplasm has suffered severely. In some instances it has disappeared, leaving the nucleus bare.

FIG. 10.—Leucocytes from fæcal films of amœbic dysentery, to show digestion of cytoplasm. Schaudinn-Heidenhain-Wenyon stain. Compare the nuclei with those seen in bacillary films.

FIG. 11.—A single field from the intestinal contents of the case of gangrenous amœbic dysentery mentioned above, showing a lymphocyte, a mucosal cell, a polymorphonuclear leucocyte, and a red blood cell. Schaudinn-Heidenhain-Wenyon stain. Zeiss 1/12, Comp. Oc. VIII.

II. *Bacillary Dysentery.*

FIG. 12 (original in colours).—Fæcal film from a case of acute bacillary dysentery. "W" stain. Zeiss 1/12, Oc. II. *B. Shiga* isolated. Compare with Fig. 3.

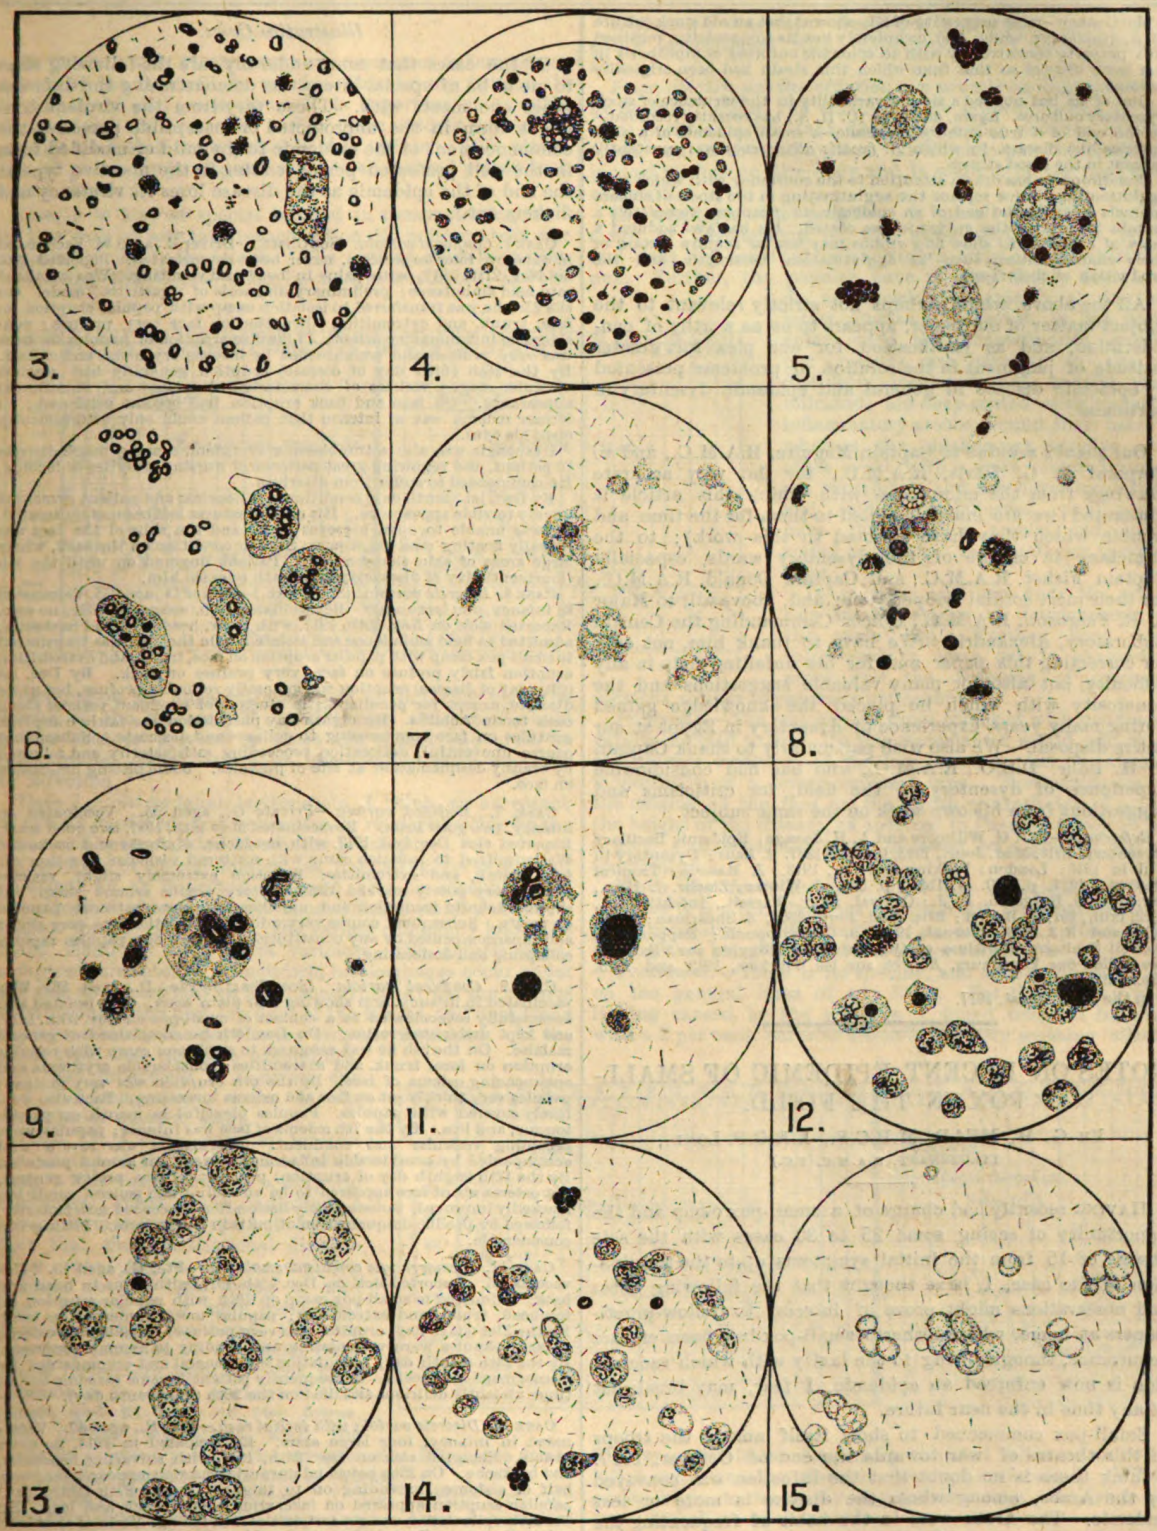
FIG. 13.—Fæcal film from a case of acute bacillary dysentery. "W" stain. Zeiss 1/12, Oc. II. *B. dysenteriæ* mannite-fermenting type isolated. Drawn in black and white. The cell at 1 o'clock contains an ingested red blood corpuscle.

FIG. 14.—Fæcal film from a case of acute bacillary dysentery of about 1 week's duration (Schaudinn-Heidenhain-Wenyon stain, Spencer 1/12, Oc. II. *B. dysenteriæ* mannite-fermenting type isolated). Note the fragmentation of the nuclei and the regular outline of the cytoplasm.

FIG. 15.—Fæcal film fresh preparation in saline from stools of subacute bacillary dysentery unstained. Spencer 1/12, Oc. II. (*B. dysenteriæ* mannite-fermenting type isolated.) To show degenerative changes in leucocytes and formation of "ghost cells."

FIG. 16.—Polymorphonuclear neutrophile probably hydropic, from fæcal film of bacillary dysentery, "W" stain, drawn in black and white. Zeiss 1/12, Oc.V. To show fragmentation and centrifugal tendency of nuclear chromatin.

FIG. 17.—Macrophage of endothelial origin from a case of subacute bacillary dysentery (*B. dysenteriæ* mannite-fermenting type, probably *B. Tor No. I*, isolated). Schaudinn-Heidenhain-Wenyon stain. Reichert 1/12, Oc. XII. The nucleus shows early karyolysis, two polymorphonuclear leucocytes ingested.



DESCRIPTIONS OF ILLUSTRATIONS (*continued*).

FIG. 18.—Shows a similar cell with much more advanced degenerative changes from another case (technique as in Fig. 17). The cytoplasm is swollen, probably hydropic, and shows a projection resembling a pseudopodium towards 1 o'clock. Inclusion forms are represented by a polymorphonuclear leucocyte, a lymphocyte, red blood cells, and their fragments. The nucleus is not obvious, but is probably represented by a line of pyknotic chromatin granules near the periphery of the cell from 4 to 7 o'clock. There is no reason to suppose that any of the changes are artificial or extra-corporeal. (Flexner's bacillus isolated in almost pure culture from the stool.)

FIG. 19.—Leucocytes from a case of bacillary dysentery (Schaudinn-Heidenhain-Wenyon stain. Zeiss 1/12, Compens. Oc. VIII.). The largest cell is probably a macrophage with pyknotic nucleus, the smallest probably a polymorphonuclear leucocyte, and the cell of irregular contour possibly a macrophage, showing the nuclear stigmata peculiar to degeneration produced by toxins of bacillary dysentery.

FIG. 20.—A leucocyte from a fresh preparation stained with Sudan III. from a bacillary stool. To show fatty degeneration of cytoplasm (drawn in black and white). Zeiss 1/12, Oc. VIII.

MacConkey—most suggestive of all—showed that an old stock culture of *B. diphtheriæ*, which had completely lost its toxigenicity, regained this property concurrently with an epidemic outbreak of diphtheria in the same district as that from which this strain had been originally isolated.

One of us has noticed a similar variability in the virulence of stock dysentery cultures. Again, one of us (C. H. S.) has recently recorded—at the end of a true enterica epidemic—a small epidemic of a mild enterica-like disease, in which *B. fæcalis alkaligenes* was constantly present in the blood stream.

Crendiropoulo has drawn attention to the constancy with which non-agglutinating vibrios replace the agglutinating in the stools of cholera contacts towards the end of an epidemic, to disappear completely a certain time after the epidemic has ceased. He has also adduced a mass of evidence to show how vibrios may lose or acquire certain of their characteristics, such as agglutination, hæmolysis, and the production of cholera-red.

All the above, while perhaps not strictly relevant to the subject matter of our paper, appears to us as worthy of consideration, and as justification for our plea for greater latitude of judgment in the solution of problems presented by epidemic disease in general and epidemic dysentery in particular.

Our thanks are due to Captain Maguire, R.A.M.C., and to Corporal E. G. Davis, R.A.M.C., for the very accurate drawings from the microscope with which this article is illustrated (we are much indebted to them for the time and trouble which they have devoted to this work); to the clinicians in charge of the dysentery wards, especially Captain Fisher, R.A.M.C., and Captain Donald, R.A.M.C., for their most cordial coöperation; and, above all, to Major A. R. Ferguson, R.A.M.C., Officer Commanding the Central Laboratory, Alexandria. We have to thank him, not only for correcting this paper and for his unfailing help in any difficulty, but also for many valuable suggestions and the generosity with which he placed the knowledge gained during many years' experience of dysentery in Egypt at our entire disposal. We also wish particularly to thank Captain P. H. Bahr, D.S.O., R.A.M.C., who has had considerable experience of dysentery in the field, for criticisms and suggestions from his own work on the same subject.

NOTES ON RECENT EPIDEMIC OF SMALL-POX IN THE FIELD.

BY G. H. MEAD, M.R.C.S., L.R.C.P. LOND.,
LIEUTENANT, R.A.M.C. (T.C.)

HAVING recently had charge of a small-pox camp and the opportunity of seeing some 25 to 30 cases with the sole charge of 15 from the initial symptoms up to the termination of the case, I have thought that the following notes and observations might prove of interest to fellow-practitioners at home, where hitherto small-pox has been of rare occurrence, though owing to the laxity with which vaccination is now enforced an epidemic, I fear, may break out at any time in the near future.

Small-pox commenced to show itself among the troops in this theatre of war towards the end of October, 1917. I think there is no doubt that the infection was conveyed by the Arabs, among whom the disease is more or less endemic. The Arabs were in the habit of frequenting the camps for the purpose of selling their produce.

The fact that the disease was early got under control was, I think, entirely due to the following measures that were taken: 1. Vaccination or revaccination of the personnel of all troops in the infected area who had not been vaccinated within the past five years. 2. The early recognition of the first cases. 3. The rigid isolation of suspected cases, together with the isolation of all contacts. 4. The segregation of such troops from which definite cases had been removed. 5. The exclusion of Arabs from the camps.

Illustrative Cases.

Of the cases that came under my care the following seem to me to be of special interest as demonstrating the different types one meets with. These vary from the virulent confluent form in the unprotected or susceptible person at the commencement of the epidemic to the mild or modified form in the well protected person ending in the abortive type at the end of the epidemic as the disease loses its virulency and flickers out.

CASE 1. *Confluent variola.* (See Chart.)—Driver R., aged 43. Vaccinated in infancy, four large scars, never been revaccinated. Reported sick on Nov. 21st, 1917, with pains in head and vomiting. Was admitted into field ambulance; preliminary diagnosis of "gastritis" made. On the 23rd he was transferred to isolation camp with papular eruption on face, trunk, and extremities. Eruption on face very profuse; considerable inflammatory œdema. Likewise eruption of papules on back was very profuse and accompanied by intense erythema and œdema. By the 26th (fifth day of disease) eruption generally had reached vesicular stage; vesicles of characteristic loculated and umbilicated appearance. On face and back eruption had become confluent; on former œdema was so intense that patient could only with difficulty open his eyes.

Dysphagia was also a troublesome symptom, causing much distress to patient, and requiring great patience of nursing orderlies in feeding. He commenced to suffer from diarrhœa.

By Dec. 1st (tenth day) condition was hopeless and patient presented a truly terrible appearance. His entire features had become obliterated. He was unable to open his eyes at all and the skin of the face was literally floating on a sea of pus. Similar condition on the back, where large areas of skin sloughed off. Patient lingered on until the 4th (fourteenth day of disease), when death released him.

CASE 4. *Discrete variola.* (See Chart.)—Driver D., aged 33. Vaccinated in infancy, one large scar. Revaccinated 1915, unsuccessfully, no scar. Reported sick on Nov. 26th, 1917, with fever, headache, and backache; admitted to field ambulance and isolated. On the 28th was transferred to small-pox camp with papular eruption on face, trunk, and extremities; eruption fairly profuse on face, very profuse on back. By Dec. 1st (fifth day of disease) eruption was generally vesicular, profuse, but quite discrete, except for peculiar little clusters of confluent vesicles along each tendo Achillis. By eighth day pustulation was fairly complete, pustules on face commencing to collapse and desiccate. Subsequent course uneventful, desiccation proceeding satisfactorily and followed by branny desquamation at site of pustules. Some pitting noticeable on face.

CASE 7. *Modified variola.*—Private G., aged 33. Vaccinated in infancy, two good scars. Revaccinated May 16th, 1917, two good scars. Reported sick Dec. 2nd, 1917, with headache, dizziness and backache. Was admitted to isolation camp with scattered vesicular eruption on face, trunk, and extremities. Eruption extremely slight, vesicles having very poorly marked inflammatory areolæ around them, but showed definite loculation and umbilication; few scattered papules on palate. Subsequent course very mild. Pustulation was very slight and unaccompanied by any constitutional upset, the papules rapidly collapsing and desiccating.

CASE 9. *Confluent variola.* (See Chart.)—Pte. D., aged 28. Was vaccinated in infancy, arm showing four plain scars. Was isolated and successfully revaccinated as a contact of small-pox on Nov. 26th, 1917, and kept under observation. On Dec. 4th he complained of general malaise. On the 5th he was removed to small-pox camp with papular eruption on face, trunk, and extremities; considerable erythema and commencing œdema of face. By the 6th eruption was very profuse; papules very thickly set on face and œdema increasing. Back also profusely covered with papules. Papules plentiful in mouth, on palate, tongue, and lips. By the 7th œdema of face was intense; papules were becoming vesicular and confluent. Pustulation was severe and accompanied by considerable inflammatory reaction around pustules. By the 12th (eighth day of eruption) pustulation was pretty general, but œdema about face appeared to be subsiding and general condition markedly improved. Subsequently desiccation proceeded satisfactorily, followed by prolific desquamation of cutis in large pieces. Pitting was considerable.

CASE 11. *Hæmorrhagic confluent small-pox.*—Pte. G., aged 19. Unvaccinated. Reported sick on Dec. 15th, 1917, with pains in head and back. Admitted to small-pox camp on 19th with papular eruption on forehead, trunk, and extremities: papules most numerous on back. By the 21st (sixth day) eruption was very profuse; considerable œdema of face; papules were vesiculating and tending to become confluent. By the 24th (ninth day) pustulation was general and accompanied by hæmorrhage into pocks. Subsequently patient became toxæmic and at times violently delirious and died on the 29th (fourteenth day).

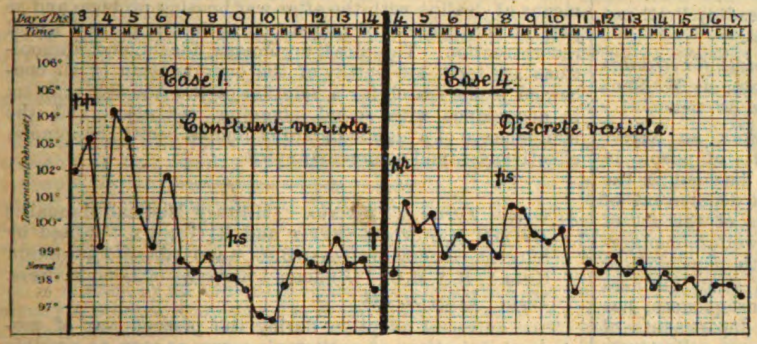
CASE 12. *Discrete variola with initial rash.*—Pte. R., aged 30. Vaccinated in infancy, four large scars. Revaccinated in 1914, no scars visible. Reported sick on Dec. 24th, 1917, with shivering, headache, and backache. On 25th petechial purpuric eruption appeared on lower half of abdomen, extending on to thighs. On the 27th (third day) papular eruption appeared on face, arms, thorax, back, and legs. By the 29th vesiculation was general, initial rash fading. Vesicles remained quite discrete. Pustulation was mild and subsequent course uneventful.

CASE 15. *Modified abortive variola.* (See Chart).—Driver O., aged 18. Vaccinated in infancy, four plain scars. Revaccinated Jan. 6th, 1918, two plain scars. Reported sick on the 9th, complaining of headache and diarrhœa. Was admitted to small-pox camp on the 13th with few scattered papules on face, arms, and back. Subsequently only a few papules matured, remainder aborting without reaching vesicular stage. On eighth day T. rose and pain in left shoulder; swelling, heat, and tenderness in region of left acromio-clavicular joint. The joint was wrapped in wool and immobilised by binding arm to body and aspirin administered. The trouble rapidly subsided; subsequent course uneventful.

Comments.

In Cases 1 and 11 the early appearance of inflammatory œdema of the face will be noted. This, in my opinion, is an important and grave sign. It is important as an early sign and aid to diagnosis, and is often evident when the papules are rather more palpable than visible. It is also a sign of grave prognosis, and when well marked points to a severe attack.

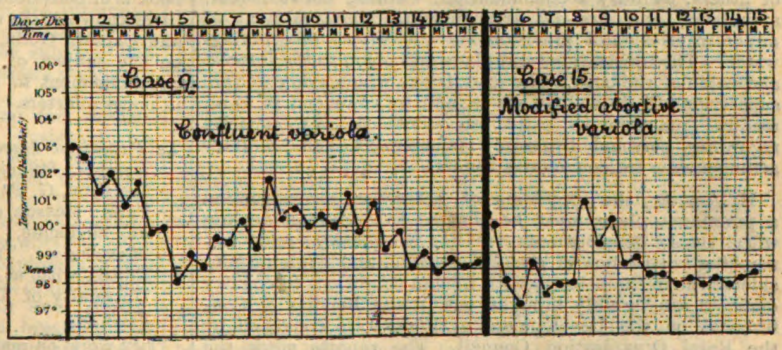
Case 9 is also of special interest in demonstrating that in this case at any rate revaccination did neither abort nor apparently modify the attack. The patient must have been incubating the disease when he was revaccinated, and the revaccination had apparently little or no influence upon the course of the disease. From this case alone one would gather that to prevent or abort the attack one must be revaccinated either before or immediately after exposure to infection.



Case 7 might be taken legitimately, I think, as an attack of variola modified, and consequently rendered mild, by the successful revaccination 11 months previously.

Case 11 is of special interest as indicating the severity of an attack in an unprotected person, also on account of the complication of hæmorrhage. Hæmorrhagic small-pox occurs in two forms. In the one, the variety commonly known as black small-pox or purpura variolosa, the constitutional symptoms are intense. Punctiform hæmorrhages occur under the skin and there may be also hæmorrhages from the mucous membranes in the first few days of the illness, and death may supervene before the papules are properly developed. In the other type, that this case exemplifies, the case progresses as a severe one and the hæmorrhages occur in the vesicular or pustular stage.

Case 12 is of a peculiar interest on account of the prodromal or initial rash. This rash, being of a purpuric character, might have indicated a severe hæmorrhagic type but for the fact that the constitutional disturbance was slight and everything pointed to the case being a mild one. Of the 30 or more cases that passed through my hands this was the only instance of an initial rash. These rashes are said to occur more commonly in some epidemics than others and to occur in two forms, the diffuse scarlatinal and the macular or measly form, the common site being the lower part of abdomen and inner side of thighs.



Case 15 is of special interest. 1. The abortive type may have been due to successful revaccination three days before the initial symptoms or to the epidemic exhausting itself and the cases becoming of a milder type. I am inclined to the latter view. 2. Arthritis is stated to be not uncommon in small-pox, and may go on to suppuration.

Of complications, pharyngitis and dysphagia were present in the severe cases, together with a certain amount of laryngitis and bronchitis. The fact that we escaped serious complications such as corneal ulcers, iritis, otitis media, &c., I attribute in no small measure to the care and attention the nursing orderlies gave to keeping the eyes, nose, and mouths of the patients clean and free from all noxious matter.

Differential diagnosis.—Small-pox in its mild form might easily be confused with chicken-pox and also pustular acne.

From *chicken-pox* the eruption can usually be distinguished by its distribution. In small-pox the eruption tends to be more profuse on the face, back, and upper portions of the chest, and on the extremities. In chicken-pox the eruption is most profuse on the body and is scantier on the face and extremities.

In small-pox the eruption is usually in the same stage of development in the same part of the body and does not come out in successive crops, as in chicken-pox. Further, the papules have a hard shotty feel and do not develop so quickly as in the latter disease. Moreover, in the vesicular stage the characteristic small-pox vesicles are circular in shape, distinctly loculated, and usually umbilicated, are deep-seated, with definite inflammatory areolæ around their bases; whereas the chicken-pox vesicles are often ovoid, with a more rounded apex, are superficial, and are never loculated, and seldom umbilicated, and never have the definite areolæ and infiltrated bases that the small-pox vesicles have.

In *pustular acne* one finds the eruption in all stages of development in the same site. Further, acne pustules tend to come out in successive crops and the presence of scars of previous attacks is generally noticeable.

Prognosis.—The majority of those attacked with confluent variola are said to die. To this statement I would add that early severe erythema of the face, accompanied by œdema, is indicative of a severe confluent type. The subsidence of the œdema of the face on the eighth or ninth day—i.e., at the height of the disease, as occurred in Case 9—I took to be a good sign, especially when followed by a gradual fall in temperature.

When the fever increases after the appearance of the pustules it is a bad sign, but a subnormal temperature after the appearance of the pustules, as occurred in Case 1, is more grave, being indicative of a poor resistance.

Treatment.—There is no specific, and treatment has to be on the general lines of any fever. For the burning and itching caused by the eruption I found frequent bathing with a 2 per cent. carbolic lotion had a very soothing effect. The eyes should be frequently irrigated with warm boric lotion and attention given to the nose and mouth. When crusts begin to form oily applications seem best, such as weak carbolised oil or vaseline.

For the odour of the disease, which is very objectionable both to the nurses and patient, I found a little oil of eucalyptus sprinkled about the floor and bedding had the effect of both drowning the obnoxious smell and giving a fragrant and soothing atmosphere for the patient's respiratory passages, which are frequently more or less affected.

In conclusion, I should like to acknowledge my gratitude to my commanding officer, Lieutenant-Colonel Burke, D.S.O., R.A.M.C., for the valuable aid he rendered me in arriving at a diagnosis in the early cases.

Reviews and Notices of Books.

WAR AND HOUSING PROBLEMS.

I. *Welfare and Housing: A Practical Record of War-time Management.* By J. E. HUTTON, Manager of the Labour and Catering Department of Vickers, Ltd.; Member of the Food Investigation Committee of the Ministry of Munitions. With 12 illustrations from photographs and two plans. London: Longmans, Green, and Co. 1918. Pp. viii. + 192. Price 5*s.*

II. *Village Life After the War.* London: Headley Brothers, Ltd. 1918. Pp. v. + 118. Price 1*s.* net.

III. *New Towns After the War: An Argument for Garden Cities.* By "NEW TOWNSMEN." London: J. M. Dent and Sons, Ltd. 1918. Pp. 84. Price 1*s.* 8*d.* net.

I. War conditions have made welfare work an urgent necessity. The aggregation of vast numbers of people in munition factories and community centres has led to the establishment of welfare management as a department of social science and an indispensable section of the art of human betterment. It is now realised that welfare management must be conducted in accordance with physiological and psychological principles as well as on strict business lines. War, with its concomitants and consequences, has compelled the nation to elaborate special departments of prophylactic and remedial assistance which can collectively be grouped under the general heading of social medicine. Mr. Hutton's informing manual furnishes an interesting and practical work which will prove of real service to many medical advisers and will do much to stimulate endeavours for the establishment of medico-sociological work for factory workers on a scientific and effective foundation. The descriptions are based on actual experiences in connexion with the various war industrial centres conducted by the firm of Vickers, Ltd. The work formulates the essentials of welfare supervision, explains measures for temporary and permanent housing, and describes principles and practices governing catering, the conduct of canteens, and the estimation of food values. There are also suggestive chapters on motor transit, amusements, works police, and industrial unrest. The information in the chapter on Hospitals and Medical Service is of particular medical interest, and we also direct attention to the helpful section which deals with welfare work from the women's point of view. There are appendices dealing with certificates of fitness, sanitary accommodation, washing conveniences, ambulance and first-aid arrangements, the treatment of minor injuries, and provision for the supply of drinking-water. The illustrations and plans add much to the interest and value of the book. The work is one which every welfare supervisor will do well to study, and we commend it to all medical practitioners called to advise in any capacity regarding personal hygienic management and sanitary arrangements for community benefit.

II. Among the problems of after-war reconstruction a prominent place must be allotted to questions dealing with rural developments. The complexity and far-reaching importance of social, economic, and hygienic considerations in the betterment of human conditions in country districts are forcibly brought out in the Reports of Conferences on the Development of Rural Life convened by the Rural Organisation Council. The reports merit the serious study of all medical officers of health and others interested in the protection and progress of human health and happiness in country districts. Amongst the subjects discussed are means for the increased production of food, legislative and other measures for the organisation of satisfactory conditions particularly in view of demobilisation, wages, rural credit, coöperation, housing, rural planning, de-urbanisation of industries, education and social amenities, provision of village community centres, protection of commons, provision of open spaces and the arrest of rural disfigurement, rural continuation school buildings, and the development of country industries and handicrafts. Such a brief enumeration is sufficient to indicate the importance of the volume of transactions and the aims of the Rural Organisation Council, the headquarters of which are at 25, Victoria-street, Westminster, London, S.W. 1.

The objects of the Council are thus defined:—

"To improve the conditions of Rural Life in Great Britain, and for those purposes to federate and secure the harmony and coöperation of any subscribing and approved non-party societies or associations concerned with rural life, while preserving their separate individuality and independence, and in particular to assist the publicity work and the financial needs of the federated societies and associations and generally to take steps for the promotion of agricultural prosperity in Great Britain, and to pursue or carry out any other lawful objects or functions which may conduce to the above objects or any of them."

III. An informing brochure has been issued to expound the aims of the National Garden Cities Committee, the headquarters of which are at 19, Buckingham-street, Strand, London, W.C. 2. This body advocates the building of new towns and the development of existing small towns as a means of dealing with the after-war housing problem and as part of the process of industrial, agricultural, and social reconstruction. The pleas, arguments, ideals, and admonitions set forth are worthy of the consideration of all concerned in the search for a solution of the housing problem in accordance with sound planning, æsthetics, and the maintenance of a high standard of human health, happiness, effectiveness, and community spirit.

Abnormal Forms of Tetanus. (Military Medical Manuals.) By MM. COURTOIS-SUFFIT and R. GIROUX. Edited by Surgeon-General Sir DAVID BRUCE and Captain FREDERICK GOLLA, R.A.M.C. London: University of London Press. 1918. Price 6*s.* net.

THE universal adoption during the present war of prophylactic injections of antitetanic serum as soon as possible after a wound has been received has modified in many cases the symptoms of tetanus. Man has been converted from a highly susceptible to a resistant subject, and as a result local tetanus, formerly a very rare type, now constitutes nearly 20 per cent. of the total number of our cases of tetanus. It is to the credit of the authors that they were able to give the first systematic account of the various forms of abnormal tetanus. It is curious, however, that their experience does not furnish many examples of the purely local form, never spreading beyond the group of muscles originally affected, with which we are so familiar in this country. The majority of the types described by them would be classified as cases of generalised tetanus with a local onset. In view of our later experience, much of the space devoted to a rather discursive and not very authoritative account of the general therapeutics of tetanus might have been with advantage given to a discussion of the pathology and the differential diagnosis of local tetanus from the various types of contracture. The book is of considerable value as a clinical exposition of some little known types of tetanus. The editors, Sir David Bruce and Captain Golla, sound a not unnecessary note of warning on the subject of treatment, recent statistics giving little encouragement to the uncritical optimism that is prevalent in many quarters.

Le Paludisme Macédonien: Caractères Cliniques et Hématologiques, Principes de Thérapeutique. Par P. ARMAND-DELILLE, G. PAISSEAU, P. ABRAMI, et HENRI LEMAIRE. Paris: Masson et Cie, Editeurs Libraires de l'Académie de Médecine. 1917. Price 3 frs. 50. *Malaria in Macedonia.* Translated by J. D. ROLLESTON, M.D. Edited with a Preface by Sir RONALD ROSS. London: University of London Press, Limited. 1918. Pp. 115. Price 6*s.*

THE work on malaria published in this country during the last year has established for most of us the following three things: (1) that only by a microscopic examination can a diagnosis of malaria be made; (2) that it is unscientific to speak of the treatment of malaria, when we should distinguish between the treatment of simple tertian and malignant tertian malaria; and (3) that it is essential when we speak of "curing" malaria to state clearly what we mean by the word "cure." "Cure" as regards malaria strictly means that the parasites in the body have all been killed. As we have at present no means of ascertaining whether this is so or not, our only means is to examine the blood periodically and determine whether or no parasites are present in the blood. A rigor by itself is no evidence of malaria, not even in a case that has shown parasites, for a reference to the records of the work done in this country will show, even in malaria cases, rigors without parasites in

the blood. The nature of these remains to be determined just as much as the nature of any other rigor of unknown origin. If we are to judge the value of the curative treatments for simple tertian malaria recorded in the last chapter of this book we must have these facts in our mind. We see no means of deciding whether any of them are of use, when nothing is said about the observation period. We cannot observe patients for ever, but we can only estimate the value of "Job's treatment," "the Italian treatment," "Carducci's treatment," or "Ravaut's treatment" (p. 109) if we know for how long these treatments have "cured" their cases, whether for one day, one week, one month, or one year. As regards the treatments themselves the reasons for them are not given, and we are asked to accept an *ipse dixit* as equivalent to a conclusion based on facts. In the important matter of curative treatment, as distinct from the treatment of a paroxysm, we find no guidance in this work.

The authors regard primary malaria as invariably due to the malignant tertian parasite and secondary malaria as due to the simple tertian malaria parasite. Not all observers in this country will agree with their view, for infections originating in this country where the first attack was due to the simple tertian parasite have been recorded. It will be gathered from these remarks that we do not consider all the authors' statements proved, but as a basis for further study the book will be found of great use, and it should be in the hands of all who are called upon to treat malaria. The work is marked by an admirable clearness of style, and the summary of clinical symptoms due to the different species of parasite is excellent.

I. *Minor Maladies and their Treatment.* By LEONARD WILLIAMS, M.D.Glasg., Physician to the French Hospital. Fourth edition. London: Baillière, Tindall, and Cox. 1918. Pp. xi. + 402. Price 7*s.* 6*d.* net.

II. *The Art of Keeping Well.* By RONALD CAMPBELL MACFIE, M.A., M.B., C.M., Hon. LL.D. Aberd. With one colour and three half-tone plates. London: Cassell and Company, Ltd. 1918. Pp. xi. + 244. Price 6*s.* 8*d.* net.

I. Dr. Leonard Williams's book, first published in 1906, is now in its fourth edition. The author exposes in a preface the inadequacies of existing methods of medical training which permit the young practitioner to enter on his professional life incompletely equipped for dealing with derangements which, in all probability, will form the major part of his practice, and thus fully justifies what follows in his book. The work deals with colds, coughs, and sore-throats, indigestion, constipation, diarrhœa, vomiting and giddiness, rheumatism, neuralgia, and headache, goutiness, and minor glandular insufficiencies. There are informing chapters on the maintenance of general health, the care of old age, the supervision of mentally deranged subjects, and the use of certain drugs. Dr. Williams possesses a vigorous style and writes with directness and humour.

II. Dr. Macfie has written an interesting and serviceable book on the principles of health, designing his work for non-medical readers. But it will prove of service to medical advisers who are called upon to explain physiological facts to their patients, or to lecture to nurses, ambulance and first-aid classes, as well as to those called to direct the instruction of welfare workers. The subjects dealt with relate to man's food requirements, the dietetic characters of the principal foodstuffs, digestion and absorption, the mechanism of breathing, air and climate, muscular activity, sleep, the care of the skin, breathing and clothing, and also the hygiene of the home. There are helpful chapters on alcohol, tobacco and drugs, common minor ailments, and the relationship of body and mind. Dr. Macfie has the knack of expressing in attractive form guiding truths and governing principles.

JOURNALS.

The British Journal of Children's Diseases. Vol. XV., April-June, 1918. Edited by J. D. ROLLESTON, M.D.Oxon.—Mr. R. Thompson writes on cases of urinary disease in children, which, he states, are not so common as in adults owing to the absence of obstructive causes such as enlarged prostate or pregnancy. Obstructive lesions, however, may occur as a sequel to tuberculous peritonitis or abdominal adenitis, which may cause kinking or compression of the ureter. Mr. Thompson records cases of pyonephrosis due to aberrant blood-vessels, renal calculi, or fibrous adhesions kinking the ureters in children aged from 8 to 13 years, and draws attention to the fact that in children symptoms of renal calculus may occur on the side which is not affected. The commoner symptoms of vesical calculus in children, in his experience, are frequency of micturition and incontinence. The prognosis is not good, and lithotrity should always be preceded by cystoscopy. The prognosis of traumatic stricture in children is also unfavourable; if possible the stricture should be excised and the ends sutured.—Dr. E. Bronson contributes a paper on Erythema Nodosum Associated with Tuberculosis, and records a case of acute pleural effusion in a boy, aged 9 years, suffering from erythema nodosum. Dr. Bronson concludes that the supposed relationship of erythema nodosum to acute rheumatism lacks clinical support; that the sequence of fairly well-defined prodromal stage, often with sore-throat, eruptive stage, and slow convalescent period, supports the theory of a specific disease of mildly infectious type; that the possibility of it being a non-specific cutaneous manifestation of general toxæmia must be considered; that the strong reaction to tuberculin and the clinical association of the two conditions are in favour of the tuberculous etiology. Finally, that the etiology of erythema nodosum has not yet been established.—In his article on the nature of von Jaksch's disease Dr. Gordon Ward adopts the following hypothesis. The disease is a reaction of the infantile blood-forming organs to infection. The actual infecting organism is not known, and is not necessarily specific. The particular reaction is only produced when rickets is present. There are therefore two essential factors—viz., infection as an exciting factor and rickets as a predisposing factor.—Dr. H. W. L. Barlow, in his notes on small-pox in childhood, gives an account of the recent outbreak of small-pox in the East-End of London. It was largely an affection of childhood. Of the first 30 patients 14 were under 15 years of age. Of these, 5 had never been vaccinated at all or only after the commencement of the actual illness, and 9 were vaccinated for the first time in the incubation period. The combination of a considerable degree of infectivity with a rather low virulence seems to have been a characteristic of the epidemic. Only one case, a girl aged 6½ years, died.—"Can the Clinical Manifestations of Congenital Heart Disease Disappear with the General Growth and Development of the Patient?" is the title of a note by Dr. Parkes Weber, who quotes two recent cases from the *Guy's Hospital Gazette* to show that such an eventuality is possible, and relates a similar case in a boy who used always to be cyanotic and had a tremendous thrill and a murmur audible at a slight distance from the chest. His development, however, was good, and he was ultimately passed for military service, nothing abnormal being found by the examining doctor. Dr. Parkes Weber also contributes a note on erythema iris in a boy, aged 6 years, in whom the eruption consisted of three patches, the largest in front of the trunk, and a smaller one on each side.—Mr. P. B. Roth relates a case of hæmophilia with effusion into the knee-joints in a boy, aged 6½ years. The condition at first was regarded as tuberculous, but the correct diagnosis was established by a history of hæmophilia and by the following X ray findings which Mr. Roth considers pathognomonic of hæmophilia. There were extensive wearing away and absorption of the cartilage and bone of the femur, tibia, and patella, as well as the formation of new bone at the edges and a deep shadow surrounding the bones, obviously due to distension of the synovial cavity with blood. To obviate ankylosis Mr. Roth proposed to apply two "knee-cages" to limit the movements of the joints and so prevent further attacks of effusion, and also to give regular doses of thymus gland and calcium and magnesium salts.—Dr. James Burnet records a case of pregnancy in a girl, aged 14, in whom menstruation had commenced at 12. The father was a boy of about the same age. Pregnancy lasted 268 days and resulted in the birth of a healthy male infant weighing 9 lb.—Drs. Marcel Labbé, Targhetta, and Ameuille publish the first two cases of infantile kala-azar in France. The patients were Serbian refugees, aged 6 and 9 years respectively, living at Nice, and had probably been infected by a pet dog.—Dr. E. Jeanselme and Mme. Chatelain describe an epidemic of familial syphilis in which a soldier home on leave infected his wife and indirectly five other members of the family.—In a note on a fifth cusp and hereditary syphilis Dr. C. Mantoux contests Sabouraud's claim that a fifth cusp on the inner surface of the first upper molar is invariably associated with inherited syphilis. In 7 cases with this fifth cusp examined by Mantoux none presented any history or signs of inherited syphilis, and the only two who had a positive Wassermann reaction were the subjects of acquired syphilis.—The abstracts from current literature deal with diseases of the blood, circulatory system, urogenital system, dermatology and syphilis, and school hygiene.

A RECENT Order of the Scottish Local Government Board makes the notification of ophthalmia neonatorum compulsory as from Nov. 1st, 1918.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

DRIED MILK (AMBROSIA BRAND).

(AMBROSIA LIMITED, BRIGHTON CHAMBERS, DENMAN-STREET, LONDON BRIDGE, S.E.)

THE importance of dried milk has recently been emphasised in a report of the Local Government Board reviewed in our columns.[1] The consensus of opinion of the authorities quoted in that report is in favour of the use of dried milk in infant-feeding, when, of course, breast-feeding is not available, and it appears that the physical and chemical changes produced by the processes used in the preparation of dried milk so alter its character that it is better assimilated by the infant than is ordinary cow's milk, whether raw, boiled, or sterilised. Further, even if the milk powder is not entirely soluble on reconstitution, its digestibility is not affected except for good. This probably is largely due to the fact that the casein of dried milk separates on the addition of gastric juice as a fine, soft curd, and not in lumps, as is the case with ordinary cow's milk. Such conclusions are of the utmost importance, since they justify the drying of milk and the conservation in this way of our available milk-supplies, well known to be unsatisfactory, because milk in the fluid state is perishable and liable to contamination on its way from its source to the consumer. The specimen submitted to us by the above company presents all the characteristics of a dry milk powder prepared from clean milk by an effective drying process and under strictly hygienic conditions. Our analysis gave the following results: Moisture, 1·60 per cent.; proteins, 28·71 per cent.; fat, 29·29 per cent.; milk sugar, 35·20 per cent.; mineral matter, 5·20 per cent. It will be seen that the proportion of fat is most satisfactory, and in general the results show that in this powder is preserved the complete food value of cow's milk of good quality. We understand that the dairy and works of this company are situated in Devonshire, and that, although primarily the manufacture was installed in order to supply the troops with milk food, a balance is reserved by permission of the War Office for the purpose of infant feeding.

"CLAROCIT."

(ARNOLD AND SONS, GILTSPUR-STREET, LONDON, E.C.)

"Clarocit" consists of a round tablet of a soap-like nature, and has been designed for preventing the condensation of moisture on laryngoscopic mirrors and lenses. The procedure is simple. Some "clarocit" is taken up by the moistened finger or suitable cloth and rubbed on the glass surface. A dry film is obtained when left for a few moments, which is removed by polishing. The method, according to the trials we made, answers admirably, condensation of moisture from, for example, the breath being completely prevented. The price of the tablet seems to us somewhat excessive, but of course the difficulties of all production are to-day abnormal. There are two sizes, 2*s.* 6*d.* and 5*s.* respectively, and the tablet we examined weighed not more than ¼ oz. A very small quantity, however, suffices for the purpose.

HAY FEVER OUTFIT.

(DUNCAN, FLOCKHART, AND CO., EDINBURGH. LONDON OFFICE, 155–157, FARRINGDON-ROAD, E.C.)

This outfit comprises (1) the ophthalmic test, and (2) the vaccine prepared from the pollen of Timothy grass. The diagnosis is indicated by the former and treatment by the latter. A drop of the toxin solution is instilled on the eyeball of the patient, and the strength of the solution (supplied in capillary tubes) which first causes the ophthalmic reaction is noted. The dose of the pollen vaccine is based on this indication, and is one-third to one-half of the number of units of ophthalmic solution which first produces a reaction. Thus a patient giving a diagnostic reaction with 25 units would receive 10 to 15 units of the vaccine hypodermically. The vaccine is contained in a graduated series of doses in ampoules, providing a good range for the varying indications of the patient.

[1] THE LANCET, April 6th, 1918, p. 509.

Both ophthalmic reaction solution and the pollen vaccine are prepared in the laboratory of the Royal College of Physicians, Edinburgh, in which has also been prepared for some time a tuberculin described by Professor Beraneck, director of veterinary medicine at Neuchâtel. This tuberculin is a mixture of equal parts of a filtered culture of tubercle bacilli on an albumose-free medium, and a phosphoric acid extract of bacillary bodies. It is claimed that this tuberculin is less toxic than, and equally efficacious to, Koch's tuberculin.

FLY-QUIT PRODUCTS.

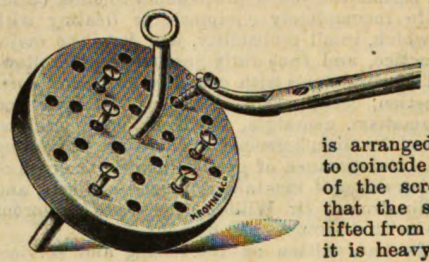
(LAWSON AND COMPANY, LIMITED, ST. PHILIP'S, BRISTOL.)

We referred to these preparations in this column in THE LANCET of Sept. 1st, 1917, since when further attention has been given to increasing their efficiency and convenience as muscicides. They are non-poisonous, and "fly-quit" spray has been found useful in rendering meats and uncooked food-stuffs fly-proof without affecting the normal flavour of the food material in any objectionable way. The concentrated preparation forms an emulsion with water which is non-staining and of broad "wetting" power. As a muscicide the toxic action is slow, so that the flies do not as a rule drop dead amongst the food or, indeed, indoors if they are free to escape. Another preparation is "fly-quit" oil, which is used against blow flies out-doors; and, lastly, there is "fly-quit" emulsion, which has been successfully employed for killing both flies and larvæ in manure and refuse heaps. The preparations are free from offensive smell and have the pleasant characteristics of wood-tar.

New Inventions.

A "SCREW STAND" FOR USE IN BONE-PLATING.

IN plating bones according to the principles of Lane I have found much time wasted and much annoyance caused by difficulty in seizing hold of each screw with the screw-holder preparatory to inserting it in the bone. I have therefore devised a screw stand which does away with all the difficulty (see figure). It is arranged at an angle to coincide with the neck of the screw-holder, so that the screws can be lifted from it in a second; it is heavy and will not overturn; it is lifted straight out of the steriliser by the ring and placed on the instrument table, so that all chance of contamination of the screws is avoided. Moreover, in seizing the screws only one hand is required, and in a typical operation several minutes are saved. The stand is made by Messrs. Krohne and Sesemann.



PAUL BERNARD ROTH, F.R.C.S.,
Senior Surgeon, Kensington General Hospital; Surgeon, City of London Military Hospital.

THE LANCET, VOL. I., 1918: THE INDEX.

OWING to the continued shortage in the paper-supply, the Index and Title-page to the volume of THE LANCET which was completed with the issue of June 29th have been printed separately, and copies have been supplied gratis to those subscribers who have, up to August 14th, intimated to us their wish to receive them. Other subscribers will be similarly supplied, so long as the stock remains unexhausted, on application to the Manager, THE LANCET Office, 423, Strand, London, W.C. Such applications should be sent in at once.

THE LANCET.

LONDON: SATURDAY, AUGUST 17, 1918.

The Small-pox Danger.

IN a report to the Local Government Board on the incidence of small-pox throughout the world in recent years Dr. BRUCE LOW has given a detailed account of the behaviour of this disease which shows its presence in almost every quarter of the globe. He sounds a warning note as to the dangers likely to arise in this country from the continued neglect of vaccination and revaccination by a large section of the public. The accumulation at home of this unprotected material is attended with considerable risks at the present time, and these are likely to become still more serious at the end of the war when large bodies of troops, as well as other persons, will arrive in this country from areas in which small-pox is endemic, or where recent epidemics have been occurring. This is no alarmist pronouncement but a justifiable and probable surmise.

In the present day many of the younger generation of British medical practitioners have had little or no opportunities of becoming acquainted with small-pox. Under normal conditions the occurrence of an imported case in a well-administered district is swiftly and successfully dealt with by immediate isolation of the patient and segregation of the contacts, along with vaccination and revaccination. But it is not so easy to deal with cases in some other countries. There are certain races among whom small-pox is almost always present, and this is the case with the Arabs inhabiting the region from Morocco to the western shores of the Persian Gulf, among whom small-pox as well as exanthematic typhus is always occurring, and who, when coming from the interior to coastal towns or to depôts on the caravan routes, convey small-pox to the susceptible individuals who may come in contact with them. An instance of this is given in a communication which we publish in our columns by Lieutenant G. H. MEAD, R.A.M.C.(T.C.), entitled "Notes on a Recent Epidemic of Small-pox in the Field." Here is given illustration of the danger from the visits to camps of friendly Arabs selling their fruit and vegetables to our soldiers and camp followers. Lieutenant MEAD describes a localised outbreak, comprising about 30 cases, of which he had the supervision, and he gives some interesting clinical facts concerning the patients under his charge. We infer that vaccination and revaccination of men in our expeditionary forces have not been so persistently carried out as in former days. Incidentally, Lieutenant MEAD shows the danger of small-pox to those who have reached middle age, and who, though vaccinated in infancy, have not been revaccinated, and have consequently long lost their previous immunity. He also illustrates the folly of postponing revaccination till after exposure to the infection and therefore too late to arrest the development of the disease; and, further, he shows the serious nature of a small-pox attack in an unvaccinated person who has been exposed to a virulent strain of the infection. Lieutenant MEAD'S "Notes" are worth study by those who wish to keep themselves posted up in the possible occurrence of small-pox, first in our expeditionary and secondly in our home communities, wherever somewhat analogous conditions occur.

Dr. BRUCE LOW, in his report, refers to the disastrous pandemic of small-pox which began during the Franco-German war, and which spread over the whole of Europe, extending to the western hemisphere, and causing, in Europe alone, about half a million of deaths in three or four years, of which number not far short of 50,000 occurred in England and Wales. He is evidently alive to the possibility of such sinister history repeating itself. The existing conditions of a great European war, with a battle-front from Flanders to Mesopotamia, involve countries in which small-pox is already present; in addition to this we have to reckon with the displacement from their homes of large numbers of the poorer classes, as well as refugees, deported populations, and prisoners of war, many of whom are unvaccinated; and their aggregation takes place under unwholesome conditions of over-crowding, distress of mind, and privation, with consequent lowering of vitality. Now all these things are likely to intensify the type of the disease. Should such virulent strain of infection be introduced into this country, with its accumulations of unvaccinated children and unrevaccinated adults, it is more than probable that a serious epidemic would follow. The situation would be further aggravated at the present time if the epidemic began in the absence on military service of many of our medical officers of health, public vaccinators, inspectors of nuisances, vaccination officers, and other officials, who in ordinary circumstances could be trusted to deal successfully with the early manifestations of a small-pox epidemic. The public who have in a large measure lost their former dread of small-pox in consequence of its comparative disappearance from our land, and have, therefore, neglected vaccination, would almost certainly suffer severely. Dr. BRUCE LOW'S report comes as a timely reminder that with all our boasted progress in sanitation and preventive medicine we cannot afford to ignore the danger of small-pox; nor can we continue as a nation to neglect the only prophylactic against it known to medical science—namely, vaccination and revaccination.

40 D.

THE Regulation under the Defence of the Realm Act commonly known as 40 D having now been in force for some months, it is not too early to begin to inquire into its value as a measure of public health, for evidence is becoming available on which to base a judgment. It must be as a public health measure that the Regulation stands or falls, since it was introduced as such, and was not held out by its promoters either as a device for making promiscuous sexual intercourse safe for men or as a form of duress for women of loose morals.

The public health intent of the Regulation is made evident from its phrasing, which runs as follows:—

"No woman who is suffering from venereal disease in a communicable form shall have sexual intercourse with any member of H.M. Forces or solicit or invite any member of H.M. Forces to have sexual intercourse with her."

Now, in the first eight charges under the Regulation in various parts of the country, from Manchester in the north to Portsmouth in the south, four convictions were obtained and penalties of two to six months' imprisonment with or without hard labour inflicted. In four cases the accused was acquitted, although in one of these the woman was committed to prison for a month for keeping a brothel. Last week, at a London police court, the solicitor acting for the Commissioner of Police said that so far as his experience went prosecutions under the Regulation had not turned out satisfactorily; of five cases conducted by himself all had failed. The difficulty, he added, was due to the time elapsing between inception of the disease and examination of the woman. In the case actually before the court no hardship, he said, could be alleged, as the woman was a prostitute. In a similar case brought early last month before a London police court a charwoman was fined for assisting in the management of a disorderly house, although the magistrate acquitted her under Regulation 40 D after the gaol medical officer had reported that he could find no evidence of disease. We observe, therefore, that up to the present time, in a large proportion of cases, it has proved impossible to establish the existence of "venereal disease in a communicable form," although in some at least the women were demonstrably living a disorderly life. It may without unfairness be concluded that a searching bacteriological examination, involving the use of the vaginal speculum and the expression of secretion from the urethra and cervix uteri, may fail to establish evidence of infection in cases where clinically it was almost certainly present. And this conclusion is entirely in harmony with the admitted difficulty—some experienced clinicians go so far as to call it impossibility—of curing gonorrhœa in the female. Quite apart from the fact that the woman may be acting merely as carrier of infection without at the time clinically suffering herself from venereal disease, it may frequently happen that an infective spot is present in the genital tract which is beyond the reach of the most exhaustive examination. Put shortly, the coitus test is more delicate than the bacteriological. With regard to the latter test, Regulation 40 D runs:—

"A woman charged with an offence under this regulation shall ..... be remanded ..... for the purpose of such medical examination as may be requisite for ascertaining whether she is suffering from such a disease."

But in practice no medical examination suffices to ascertain the presence of infection, and this negative aspect in itself, we believe, discredits the Regulation as a public health measure. Also difficulty may arise in regard to positive medical evidence. In a case where the woman is shown to be infectious, and where sexual intercourse has taken place, the length of time elapsing between inception of the disease and examination of the woman, adduced by counsel as a legal difficulty, may leave the medical examiner himself in doubt as to which party infected the other. Either the man alone, or both the man and the woman, may have been suffering from communicable disease at the time they met, and the statement of either party as to the date of possible infection is evidently always to be taken with reserve. Great probability may exist as to the precise nature and order of the events, and yet that degree of certainty may not be present which will enable the medical examiner to speak without reserve in a matter which involves such serious issues.

We have confined our criticism thus far to the purely public health aspect of Regulation 40D. We agree entirely with Mr. MACPHERSON'S recent statement in the House of Commons that the War Office ought to do everything to preserve the health of the troops, but we are not sorry to find wanting as a public health measure a regulation which has aroused such widespread opposition from all who wish to see the law dispensing even-handed justice. Solicitation is difficult enough to define, and should be abolished as a legal offence, unless the attitude of intending to be solicited is recognised as a contributing offence. With regard to the actual duties of the examining doctor, examination of a woman, in her own interest, for the relief of present suffering or future disability, and in order to carry out the treatment found to be necessary—however disagreeable or painful the episode may be to the patient—is not in itself an idea foreign to medicine. But the position is essentially altered when examination is not primarily or necessarily made for the purpose of consequent treatment. We believe that the cause of public health, which the medical profession has increasingly at heart, will not be advanced by any legal measure which does not commend itself to the moral sense of the majority; but whichever way that sense may work in respect of Regulation 40 D, the enactment appears to be condemned by its own futility.

The Medical Side of Chemical Warfare.

A SERIES of reports which demand more than passing comment have just come into our hands. They are issued by the Chemical Warfare Medical Committee, a body appointed last January by the Director-General of the Army Medical Service to advise him on the scientific medical aspects of chemical warfare. The committee as now constituted has Professor LEONARD HILL, F.R.S., as chairman, Dr. J. S. EDKINS as secretary, the other members being Mr. J. BARCROFT, F.R.S., Professor W. M. BAYLISS, F.R.S., Professor A. E. BOYCOTT, F.R.S., Dr. H. H. DALE, F.R.S., Sir WALTER FLETCHER, F.R.S., Dr. J. S. HALDANE, F.R.S., Lieutenant-Colonel J. C. MEAKINS, C.A.M.C., Major H. S. RAPER, R.A.M.C., and Dr. F. SHUFFLEBOTHAM, with corresponding members in France and Italy. The series consists of eight reports issued by this committee during the present year dealing with various phases of the pathology and treatment of gas poisoning—matters which have hitherto been kept secret. A number of the reports are still to

be regarded as confidential, while the remainder may be treated in any way likely to advance the interests of the medical public.

It has long been evident to us that records of this sort were necessary if the medical profession was to be of full service to the country, and the knowledge that official information on the pathology and treatment of gas poisoning is forthcoming, and that there is a definite organisation for dealing with it, will do much to allay anxiety. The subject of gas poisoning, considered as a part of medical knowledge, presents novel features in scientific development. For some decades pathological inquiry in this and other countries had been directed, and with good reason, mainly towards bacteriology and its kindred subjects, such as protozoology. These, together with the always essential studies of morbid anatomy and morbid histology, occupied the minds of our principal pathological workers when, in April, 1915, gas warfare commenced. Casualties of an unconsidered type threatened whole armies and the fate of nations, and to the medical profession the world looked for counsel. At first, gas warfare consisted simply in the use of pulmonary irritants, the treatment of its effects being dependent upon the answers to a few simple questions, such as the following: "How much oxygen does this man need to preserve life; how can this be reduced to a minimum; how much do the pulmonary conditions admit of his obtaining, and for how long?" The whole pathology and treatment of gas poisoning had clearly to be worked out from first principles. In this country happily we are rich at the moment in authorities on the physiology of respiration, and of these experts the Chemical Warfare Medical Committee appears to have made full use.

The novelty of the subject has had a striking effect upon the composition of the Committee itself. It has brought into prominence a school of young clinicians, all of whom had, we believe, published scientific work before the war. Such men as Colonel MEAKINS, Captain G. H. HUNT, and Captain R. A. PETERS had been known to us as producing sound work in our medical centres; it is valuable to have such observers associated with our specialist workers. For it is essential that such a novel subject as the treatment of gas poisoning, and one which is ramifying in so many directions and which has relations with our own production of materials of war, should be in the hands of a young and capable school. Continuing activity is evident from the fact that some of the pamphlets which we have received are already obsolete in parts and undergoing revision. We trust that it may be possible to issue No. 1, dealing with the treatment of gassed cases at the front, to medical officers as soon as it has undergone the necessary revision. For practitioners in England a knowledge of the early pathology and treatment of these cases is eminently desirable, and we are confident, therefore, that as soon as secrecy can be relaxed the committee will make use of their freedom. In the meantime we advise all practitioners who are interested in gassed cases to apply to Dr. EDKINS at the Department of Physiology, Bedford College, London, N.W., for such numbers of the series as may be had.

Annotations.

"Ne quid nimis."

THE BRITISH SCIENTIFIC PRODUCTS EXHIBITION.

IT is early yet to deal in detail with the splendid collection of British scientific products now on view at King's College, since at the informal opening on Monday last the work of arranging the exhibits had not been completed. There was enough, however, already on view to show that the chief purpose of the exhibition promises to be fulfilled in a most gratifying way. The belief is amply justified that such an exhibition at the present time will have a most stimulating influence upon scientific and industrial research and upon manufactures, and that the highest permanent interests of the nation will thus be promoted. The products shown come under three categories, as follows:—(1) Products imported chiefly from enemy countries before the war, but now made in this country; (2) products in the manufacture of which we excelled in this country even before the war and exported to enemy countries; and (3) products in the manufacture of which considerable developments have taken place during the war. A very large number of the exhibits have a direct medical interest, as, for example, the surgical, bacteriological, and pathological appliances, including X ray apparatus in Section 8, the optical apparatus in Section 4, and the pharmaceutical and medicinal preparations, including the organo-metallic preparations shown in Section 1, comprising chemical products and processes. The exhibition was formally opened, after an impressive speech, by Lord Sydenham, President of the British Science Guild, on Wednesday last, when the stalls presented a remarkable object-lesson as to what British scientific workers are capable of doing. With the object of ensuring an intelligent interest in the several exhibits, men well grounded in their subject attend the stalls to give any explanation which is sought, and from time to time short lectures and addresses will be given dealing with the departments and features of the exhibition. By this excellent plan public attention should be effectively directed to the vital necessity of developing our scientific industries and of applying to them the results of scientific research. Altogether the idea is admirably conceived, and the occasion will doubtless lead to results of far-reaching importance to British scientific manufactures. The exhibition will be kept open until Sept. 7th, and thus presents a remarkable opportunity to the public of obtaining ocular demonstration of British scientific capability.

MALARIA IN FRENCH WEST AFRICA.

DAKAR is a very malarious port, numerous infected mosquitoes invading the ships as they enter the inner harbour. Each of three French ships which lay there for four months had about 400 cases on board, and a Senegal regiment had an enormous number, 97 per cent. of its strength, attacked. Another ship which passed there the latter half of two consecutive years had in the first period 169, in the second 473 cases. The worst month in each year was October. Of the first attacks, 35 per cent. were tertian, 33 per cent. remittent, while 24 per cent. had but a single pyrexia, and these last by no means those with the fewest parasites in their blood. The story is told in the *Archives de Médecine Navale* for July by Dr. Rouche of the French Navy, who, being well

acquainted with his shipmates, was able to recognise those of them who, during the fortnight of incubation, while their temperature was still normal, were about to be attacked, for their faces, he says, were drawn, their complexions leaden, and a yellow colour spread over their eyelids and round their eyes, their conjunctivæ, too, being slightly jaundiced. The importance of the disease is obvious, for on one day in October, at sea, they had 112 men in bed with malarial fever, and the work of the ship could hardly go on. Dr. Rouche notes how dangerous it was to lie at Dakar; a single day's visit in October started a malarial epidemic in the ship. For prophylaxis it is proposed not to keep any ship there, but to send them cruising to and from the Canary Islands. Quinine prophylaxis (4 gr. quinine daily) is recommended, but there are many men who will not take it. The treatment laid down is: on the first day, nothing but a purge, next day 10 gr. quinine morning and evening as long as the pyrexia lasts, and daily till the temperature is well down, with ¾ gr. of arrhenol daily for a week. 10 gr. of quinine are given daily during the apyrexia, and 15 gr. the evening before a relapse is due.

IRELAND AND THE MINISTRY OF HEALTH.

THE announcement made recently by Mr. Bonar Law that the Government did not contemplate including Ireland in the proposed Ministry of Health Bill has taken the Irish medical profession by surprise. Ireland is greatly in need of a development of her public medical services, which could best be undertaken by a Ministry of Health. The habit of omitting Ireland from legislation dealing with matters of health is hard either to explain or justify, but it is a fact that Ireland has not shared in the health reforms of the past 20 years. The National Health Insurance Act does not carry medical benefits in Ireland. There is no provision for the medical inspection of schools and school children in Ireland. It is only within the past few months that a Midwives Act has been enacted for Ireland, 16 years later than legislation for England. But it is in the ordinary administration of public health that Ireland lags farthest behind Great Britain. In the whole country there are only two whole-time medical officers of health. In fact, in all matters of health, Ireland is almost an untilled field, or a field only tilled in a few patches. The profession had hoped that with the establishment of a Ministry of Health this backward condition might have received due consideration, and proper schemes of development might have been inaugurated. No doubt there would be differences of opinion as to the best method by which the Ministry of Health should be applied to Ireland, but on the general principle there could hardly have been any difference. The Irish Medical Committee, which represents professional opinion in Ireland, declared itself in favour of the establishment of a Ministry of Health, and the Royal College of Physicians of Ireland has expressed itself in the same sense.

THE PREVENTION OF SIMPLE GOITRE BY ADMINISTRATION OF IODINE.

IN the *Archives of Internal Medicine* for July Dr. O. P. Kimball and Dr. D. Marine have brought forward cogent evidence that "simple goitre is probably the easiest of all known diseases to prevent." Their method is the administration of small doses of iodine. Iodine is, of course, an old and most important remedy in the treatment of goitre, but its prophylactic use seems to be entirely new. A census of the condition of the thyroid gland of all girls from the fifth to the twelfth grades in the schools of Akron, Ohio (evidently a very goitrous district), was made. In April, 1917, 3872 girls were examined, and the condition of the thyroid gland was found to be in percentages as follows: normal, 43·5; slightly enlarged, 49·8; moderately enlarged, 6·3; markedly enlarged, 0·18; adenomas, 1. In May, 2 g. of sodium iodide were given in 0·2 g. doses each school day to a number of pupils in grades from the fifth to the eighth, and 4 g. in 0·4 g. doses to pupils in the higher grades. In November the pupils taking the treatment were re-examined, with the following results. Of 283 normal thyroids on the first examination all had remained normal; 287 small goitres had remained unaltered; 141 small goitres had disappeared; 2 small goitres had increased; 34 large goitres had remained unaltered; and 17 had decreased. On the other hand, in pupils not taking the treatment 637 normal thyroids had remained normal and 259 showed slight goitre; 759 small goitres had remained unaltered, 10 had disappeared, and 103 had increased; 106 large goitres had remained unaltered and 5 had decreased. Thus, not a single pupil with a normal thyroid who took iodine showed an increase, while 26 per cent. of those who did not showed definitely enlarged thyroids—some moderately large goitres. More than prophylactic results were obtained. One-third of the small goitres had disappeared and one-third of the "moderate" showed a decrease of 2 cm. or more. Of 1000 girls who took the treatment only 5 developed any noticeable rash, and this was evanescent. The possibility of producing Graves's disease by the treatment was considered, but no evidence of this was observed. As the results were so definite, when the treatment was repeated in November, 1917, only 2 g. of the iodide were given to the pupils in the higher grades. At the time of making this report it was intended to repeat the treatment in April, 1918.

THE SMALL HEART IN TUBERCULOUS SUBJECTS.

FREQUENT observations on patients sent for radiological examination for the diagnosis of tuberculosis have enabled Dr. Carlo Guarini[1] to collect a large number of cases of the small median heart which is said to be characteristic of tuberculous or pre-tuberculous patients. Rokitanski was one of the first to draw attention to the small size of the heart, which he considered congenital and a sign of infantilism, and Albert-Weil more recently described it as a frequent occurrence in individuals who were tuberculous or predisposed to tuberculosis. Barjon also noticed that the tuberculous were habitually the subjects of a median heart which overlapped only to a small extent, to right and left, the central shadow. According to this observer, the median heart is indicative, if not of tuberculosis, at least of a predisposition to it, while, on the contrary, the existence of a large heart in an individual suspected of pulmonary tubercle is of favourable interpretation. Vaquez and Bordet drew attention to the small narrow heart suspended from a long aorta, the so-called "dropping heart" (*cuore a goccia*), which, however, they regarded as a physiological variety and having no pathological significance, arguing that if it be true that a small vertical heart is often found in tuberculous patients it is

[1] La Riforma Medica, June 22nd, 1918.

due rather to the peculiar formation of their thorax than to the pulmonary tuberculosis itself. Dr. Guarini's observations throw some light on these different views and tend to show that the small heart and the dropping heart are pathological entities in close dependence on the hypo-evolution of the other organs of the individual and on the hypoplasia of its anatomical parts. Of 1300 tuberculous patients subjected to radiological examination he found the small median heart in 68 per cent. of the cases, whereas the dropping heart was only found in 0·13 per cent. He considers that the former is a hypoplasic heart, while the latter, also hypoplasic, is due to an arrest of development of the heart and aorta during extra-uterine life; that both these varieties must be considered pathological entities, having no relation with the atrophic heart found in other morbid conditions, and that their presence is a far more reliable aid than clinical symptoms in the diagnosis and prognosis of tuberculosis. Few practical physicians are likely to take this view. Dr. Guarini has also made observations on the inclination of the heart's axis in the same class of patients. The older anatomists and clinicians fixed this inclination between 55° and 60°; but Moreau, from radiological investigations on 100 normal adolescents and adults, found that in 74 per cent. the inclination varied between 65° and 78°. Dr. Guarini found in 100 patients examined for diseases of the chest the inclination was in 6 per cent. between 20° and 30°, in 37 per cent. between 30° and 40°, in 41 per cent. between 40° and 50°, and in 16 per cent. between 50° and 60°. Thus the angle of inclination varied with the individual, or rather with the morphological constitution of the individual, between 20° and 60°, which may be considered the extreme limits in tuberculous or pre-tuberculous subjects. It should be noted, however, that there may be small hearts whose axis of inclination exceeds the above limits, and these must also be considered pathological, since they represent hearts with incompetent valves or stenotic orifices.

CANADIAN COLLECTION OF MEDICAL WAR SPECIMENS.

FROM 1914 onwards the Canadian Army Medical Service has coöperated with the Army Medical Service in the endeavour to obtain adequate medical records of the world-war. Being, perhaps, familiar with the great collections which the United States possess from their Civil War in the Army Medical Museum at Washington, the C.A.M.C. has steadily been working ahead to obtain material of all sorts which will worthily illustrate the medical aspect of the war. In 1915 the Royal College of Surgeons of England, being the custodian of the Hunterian Museum of the College, which may be described as the National Medical Museum of the Empire, offered its services to collect and prepare the medical material for the whole British Expeditionary Force. In national spirit the College came to the assistance of Canada and the other Dominions, and offered to receive and care for material collected by their medical units—to be, in fact, the clearing-house in which this material could be collected, and later allocated to the rightful possessors. Thus all pathological and other material from Canadian hospitals, whether overseas or in Great Britain, finds its way to Lincoln's Inn Fields, and has been reviewed in Professor Arthur Keith's annual report which has recently appeared. Already a large amount of this material has been sent to Canada, and at the notable medical gathering in May at Hamilton, Ontario, to which we have already called attention (THE LANCET, July 27th, p. 120), when five of the most important medical associations of Canada met together, one of the outstanding features was the exhibition of specimens thus sent over. At the concluding session of the congress one of the main resolutions passed was "that whereas these war specimens have aroused great interest both among military surgeons, civil practitioners, and the general public visiting the Congress, and since their further collection and their adequate preservation and development into a great Canadian War Museum must be of the utmost value in the education of the Canadian Army Medical Corps at the present time, as well as a fitting memorial to future generations of the sacrifices of our troops, be it resolved that a copy of this statement of appreciation be sent to Surgeon-General Fotheringham, D.G.M.S., with the recommendation that it be forwarded to the Minister overseas, as an expression of the warm support which the development of a Canadian Army Medical Corps Museum received from the members of the Canadian Medical Association." Sir Robert Borden's visit to the Royal College of Surgeons of England, on the afternoon of Wednesday, August 14th, was thus an act of appreciation on his part of the services rendered to Canada by the English College, and was the formal opening of the exhibition now being held there. This exhibition is not the sum total of Canadian war specimens, but includes some of the more interesting of the specimens. Among these may be mentioned wax and plaster casts of war injuries, made at Orpington by Major F. Lessore and his staff; bird's-eye views and drawings by Captain Mathews, C.A.M.C., a well-known Canadian artist, of the different buildings in Great Britain and overseas occupied as Canadian war hospitals; pathological specimens, photographs, and X rays of war wounds and diseases. The whole affords a striking idea of the human interest there is in the records of the sufferings undergone by the soldiers, and the endeavours made by the medical services to counteract those sufferings.

IN connexion with the scheme for the employment of officers and men invalided from the Navy and Army it has been suggested that in cases of shell shock, gas poisoning, and general breakdown such men as contemplate life in the Far Eastern Colonies and dependencies would be well advised first of all to submit themselves for examination by some medical expert in tropical disease.

THE King of Italy, on the recommendation of the Italian authorities, has conferred the following Honours on the British members of the Royal Italian Military Medical Commission, in recognition of the voluntary and valuable services which, in conjunction with their Italian colleagues, they have rendered in examining the Italian recruits: T. Vincent Dickinson, M.D., Officer of the Order of the Crown of Italy; James Donelan, M.D., Officer of the Order of the Crown of Italy; Andrew Morton, M.D., Cavalier of the Order of the Crown of Italy; Andrew Currie, M.D., Cavalier of the Order of the Crown of Italy. The Italian authorities take the opportunity of cordially thanking the British and Italian members of the Commission and the President, Dr. Commendatore Melandri, for the care and zeal displayed in the work.

A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

METEOROLOGICAL OFFICE: ADVISORY COMMITTEE ON ATMOSPHERIC POLLUTION: SUMMARY OF REPORTS FOR THE MONTHS ENDING *Dec. 31st, 1917.* *Jan. 31st, 1918.*

* Bottle broken. † Sand present with suspended solids. ‡ Result lost through accident.
§ Total content of gauge as received in chemical laboratory. ‖ Carboy broken during the month.

"Tar" includes all matter insoluble in water but soluble in CS_2. "Carbonaceous" includes all combustible matter insoluble in water and in CS_2. "Insoluble ash" includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (*a*) Approx. 9lb. per acre; (*b*) 2·56 English tons per sq. mile; (*c*) 1 g. per sq. metre; (*d*) 1/1000 mm. of rainfall.

The personnel of public health authorities concerned in the supervision of these examinations and of the analytical work involved remains the same as published in previous tables. The analyses of the rain and deposit caught in the gauge at the Meteorological Office are made in THE LANCET Laboratory.

REPORT FOR 1917 OF THE COUNTY M.O.H. AND SCHOOL M.O. OF LONDON.

PART II.—EDUCATION.

Medical inspection.—In a previous report Dr. Hamer adduced the improvement then apparent in the results of medical inspection as evidence that the solicitous care for child welfare which had distinguished the history of recent years still remained undiminished by the circumstances of war. This improvement has been maintained ever since. Moreover, a further indication of the favourable economic conditions obtaining in 1917 is afforded by the fact that the number of necessitous children receiving free meals continued to decline below the already remarkably low figures of the preceding year. It is with profound satisfaction that the medical officer records these facts, showing as they do that the horrors of war had to this extent failed to affect injuriously the rising generation. Nevertheless, we learn that certain unfavourable conditions apparently inseparable from warfare still remain unredressed. Prominent among these is the difficulty of obtaining clean and wholesome milk for the feeding of necessitous infants. On analysis half the samples of such milk already examined have been found to contain added water. Apart from a few small and localised outbreaks of dysentery in districts north of the Thames, two occurrences prejudicial to health were reported as directly attributable to the war. In the first place, there was marked increase in the prevalence of scabies, doubtless introduced by soldiers returned from abroad. Secondly, a falling off was noticed in the results of treatment of children's diseases. This was caused partly by the withdrawal of hospital facilities and partly by the failure of arrangements for "following up." In some degree that failure was due to the employment of nursing mothers away from home, but mainly to falling off in the supply of voluntary care workers.

Effects of Economic Conditions.

The annual individual examination of a quarter of a million children in London affords a reliable measure of the social condition of the community, with which there had previously been nothing to compare. In regard to personal cleanliness the maintenance of the *status quo ante* has been fully achieved, but only by constant vigilance on the part of the nurses. This is remarkable, in face of the persistent introduction of parasitic infection and of the increased employment of married women. While the proportion of children ill-fed and insufficiently clothed has remained low, there has been a slight reduction in that of children well dressed and shod, as contrasted with those only fairly well provided for. It would appear that economic considerations have prevailed here, and that parents are now beginning to spend more on actual necessaries and less on finery of apparel than in the earlier years of war. Scrutiny of the figures for nutrition reveals the indirect influence of war conditions on the physical condition of the children. The progressive improvement in their appearance has been maintained throughout the last two years; the number of poorly nourished children having been only half as great as in pre-war times. The returns for the third term of last year were, in this regard, the best hitherto attained. On the other hand, the proportion of children returned as of "good nutrition," as opposed to "only fair nutrition," has shown some diminution. Coöperation has been established with several infant-welfare centres. At six of these arrangements have been made by which the same premises are used for the purposes of school treatment and infant welfare, to the mutual benefit of all concerned.

The open-air schools at Birley House and Shooter's Hill are still continued. The improvement in the mental as well as the physical state of the pupils has been well marked; the benefit to debilitated and anæmic children accruing from open-air education, supplemented by generous feeding,

being especially obvious. The majority of those in attendance are children in whom the onset of tuberculosis was feared, several of them having returned from sanatoriums with the disease in an arrested state. Further coördination of school work with that of the tuberculosis dispensaries has been effected with advantage to the children. The Kensal House School for tuberculous patients has been continued and some of the playground classes have been held in the public parks. The adequacy and quality of the food supplied to the schools has been attended to, the report containing results of the analysis of samples of meals supplied to the pupils. Save as regards milk (as previously mentioned) there has been found no cause for complaint.

Personal hygiene.—There are now 25 cleansing stations in London, at most of which treatment is extended by the inclusion of scabies. More than 30,000 baths were given to 6940 children suffering from scabies. This large increase on previous records was, doubtless, caused by infection introduced into the homes mainly from abroad. During the year 799,000 children were examined by the nurses, and in 19,500 cases verminous conditions were found. 8500 of the children were cleansed by parents and the remainder by the borough councils.

Verminous conditions and infectious disease.—The year under notice was remarkable for the extent to which attack was made on problems arising out of verminous conditions. How great is the improvement in this respect within the last 30 years will be apparent to those having had experience of London school children extending over that period. But unfortunately the campaign against vermin has not until lately excited general enthusiasm, and consequently the Council's nurses who have endeavoured to combat the prevailing indifference respecting cleanliness have had a difficult and sometimes unpopular duty to perform. It is now, however, realised that the banishment of plague in the seventeenth century was probably effected by attacking the prevalence of vermin, and that the practical extinction of typhus and relapsing fevers in this country within the last half-century has been accomplished mainly by improving the conditions of the poor as regards infection with body lice. Of late years study of plague in India and of the part played by insect parasites has greatly emphasised the importance of fleas, and it may well be that it is now necessary to look nearer home. Dr. Hamer refers to the inquiries recently made in London respecting the relationship between the "flea curve" and the curve of scarlet fever; he claims that the case in favour of a flea hypothesis of scarlet fever causation is one that calls for close examination. The amount of misery and discomfort caused by flea-bites among children has incidentally been revealed, but it is not possible to allow the question to rest at this point. The demonstration of the association of vermin with the spread of infectious disease has done more than had ever before been accomplished in arousing serious interest on the subject. The fact that during the past year one London elementary school-girl out of three has been found to have "nits" in her hair is a condition of things for which the medical officer is determined that a remedy must be found. The spread of verminous conditions among soldiers and the dissemination of scabies throughout the country have enforced the moral, and it is to be hoped that the attempt to cope with this national danger will meet with general support.

Among the commoner diseases of school life there was less prevalence than usual. Scarlet fever was reported in 6000 instances and diphtheria in 8000. Measles and German measles occurred among school children in 27,000 instances. Whooping-cough was less prevalent in 1917 than in any year of the preceding five.

THE LATE MR. WILLIAM FINGLAND, L.R.C.P., L.R.C.S. EDIN.—Mr. W. Fingland, honorary consulting anæsthetist to the Liverpool Royal Infirmary, died on August 1st from cardiac failure at his residence, Rodney-street, Liverpool, at the age of 66 years. Educated at Liverpool, he qualified with the licentiateship of the Royal Colleges of Edinburgh in 1891 and settled in practice at Liverpool, where for 25 years he was on the staff of the Royal Infirmary. He was vice-president of the section of anæsthetics when the British Medical Association held its meeting in Liverpool in 1912. Mr. Fingland leaves a widow and a daughter.

"Audi alteram partem."

NASO-PHARYNGEAL INFECTION AT THE ONSET OF CEREBRO-SPINAL FEVER.

To the Editor of THE LANCET.

SIR,—Lieutenant-Colonel M. H. Gordon, R.A.M.C., in his letter to THE LANCET of Nov. 10th, 1917, and in his report to the Medical Research Committee, 1917, states that "every case of cerebro-spinal fever was in reality an instance of a carrier developing the disease," and that the meningococcus was invariably to be found in the naso-pharyngeal secretion at the onset of the disease. I wish to mention the following findings as contravening the above statements, of which findings Colonel Gordon is already aware, both from my reports and from conversations I have had with him, but to which he does not allude either in his letter or in his report.

In the spring of 1916, whilst employed in coördinating the work of investigation and prevention of the outbreak at X Garrison (pages 19 and 70 of above report), I paid particular attention to the question of infection in the naso-pharynx, and excluding some earlier cases, where the results could not be relied upon, a special record was made of the results of swabbing of all patients on admission to hospital. Forty-one cases were examined on admission, and the meningococcus could be demonstrated in 19 only. There was no greater degree of infection in those cases actually diagnosed as cerebro-spinal fever than in a group of other febrile patients suffering from influenzal or other complaints who were being admitted in epidemic numbers at the same time. The symptoms of many of these, however, approached in severity those actually diagnosed as cerebro-spinal fever, and I suggested in my report that they were in many cases really caused by the meningococcus.

The swabs were taken and examined by Captain C. Samut, R.A.M.C., professor of bacteriology, Malta University, and by Captain R. R. Armstrong, R.A.M.C., at that time attached to the Central Cerebro-spinal Laboratory.

I discussed these negative results with Colonel Gordon, who was inclined to query the diagnosis. Captain Samut had, however, demonstrated Gram-negative intracellular diplococci in the spinal fluids of all the diagnosed cases, nearly half of which yielded a successful culture and were agglutinated; and Colonel Gordon had agglutinated to type the meningococcus derived from five patients who failed to show the meningococcus in the naso-pharynx. Captains Trevor Davies and E. G. Pringle, who were in medical charge of the patients, and all of us concerned, were entirely of opinion that these cases were really cerebro-spinal fever. Colonel Gordon had not seen the patients.

In my report of this epidemic I gave further details, pointing to an absence of meningococci from the fauces of patients within a period of a few hours to a few days before the onset of symptoms, as follows:—

3	soldiers	were	negatived	within	24	hours	of onset.
2	,,	,,	,,	,,	2	days	,,
2	,,	,,	,,	,,	3	,,	,,
1	,,	,,	,,	,,	4–7	,,	,,
1	,,	,,	,,	,,	7	,,	,,

These soldiers were swabbed when isolated as contacts immediately after the diagnosis of a case, and they developed cerebro-spinal fever within the period stated. 520 carriers (contacts and non-contacts) were isolated for a long period at X; none of them developed any illness.

In April, 1917, I had an opportunity of confirming the negative findings of the year before whilst on sick leave from abroad, when I was temporarily attached to the Central Cerebro-spinal Laboratory. Captain Glover, R.A.M.C., in charge of investigation of cases in the London area, kindly swabbed for me four definite cases of cerebro-spinal fever which we visited together, and in only one of these could the meningococcus be grown afterwards in the Laboratory, although two of them were tried twice. On mentioning these results to Colonel Gordon, he had a tabular list prepared of the London cases during the previous couple of months. This list comprised 19 cases, 7 of which were negative and 6 positive in the naso-pharynx; the remainder had not apparently been tested, as no results are mentioned on the list. These cases were open to no doubt, and the meningococcus was isolated from the spine in each case.

Other observers have likewise noted the absence of meningococcus from the fauces of patients. In the Advisory Committee's report it is stated that "the meningococcus has

been much less commonly found in the naso-pharynx of actual sufferers than might have been expected." Gaskell states that only 25 per cent. are infected, and mentions Netter and others as finding infection in 60 per cent. of cases of the disease.

Colonel Gordon, however, considers that the meningococcus is always present, so much so that he and other officers working with him in the Central Laboratory regard its presence as practically essential to a diagnosis. He states as follows (Medical Research Committee Report, page 19):—

"The constant presence of the meningococcus in the naso-pharyngeal secretion at the earliest stage of the disease is a point of considerable practical importance, for by the simple procedure of taking a naso-pharyngeal swab and plating the secretion on the spot cases of cerebro-spinal fever can be recognised with practical certainty within 48 hours of being called to see them. The evidence yielded by the naso-pharyngeal swab has been found by Captain Flack to be of cardinal importance in facilitating the diagnosis, particularly in early cases, in cases where the symptoms are atypical, or where the spinal fluid fails to yield a positive culture." (See also Captain Flack's record on diagnosis on page 41 of the report.)

The diagnostic application thus made of the invariable presence of the meningococcus in the naso-pharyngeal secretion of the patient at the onset of cerebro-spinal fever naturally explains why all the cases investigated are reported as harbouring the meningococcus, but this method of diagnosis does not appear logical inasmuch as the symptoms cannot be reasonably described as atypical when the physician in charge has already submitted his patient to lumbar puncture, and also because it is a well-known fact that the meningococcus as often as not fails to grow when cultured; on the other hand, there are not many bacteriologists who would place reliance in diagnosis on the result of plating the secretion from the naso-pharynx alone.

In May, 1916, I presented a report on cerebro-spinal fever based on the epidemics at X and other garrisons. Last year I applied to publish a further report on the same lines dealing with the epidemiology of the disease. I was then ordered on active service, since when I have not heard news of its publication.

In these reports arguments and statistics were brought forward to emphasise the following points:—

1. The existence of many mild and usually unrecognised cases of cerebro-spinal fever.
2. The prime importance of these mild cases on the spread of the infection.
3. The impracticability of controlling the disease by isolation of carriers.
4. The importance of recognition and of isolation of mild and severe cases, and of the provision of free ventilation during the period of seasonal prevalence as the most effective means of prevention.

I am, Sir, yours faithfully,

J. DORGAN,
Major, R.A.M.C.

Feb. 25th, 1918.

Major Dorgan's letter has taken some months to reach THE LANCET, and to avoid further delay we have submitted it to Colonel Gordon, who replies through us as follows:—

SIR,—I would remind Major Dorgan, in the first place, that pathological and bacteriological tests are far more valuable in their positive than in their negative aspect. This is well known in the case of diphtheria and tubercle, where failure to find the specific micro-organism in a single examination of material from a clinically suspicious case is recognised as being by no means conclusive. Still more does it hold with regard to the meningococcus, since the technical difficulty of isolating and identifying this highly delicate micro-organism in the naso-pharyngeal secretion is considerably greater, and success requires special training, experience, and sometimes considerable perseverance as well.

The history of the literature on the subject of the presence of the meningococcus in the naso-pharyngeal secretion of patients suffering from cerebro-spinal fever illustrates this difficulty in a striking manner, notably the experience of v. Lingelsheim, who during the Silesian outbreak at first found the meningococcus in the naso-pharyngeal secretion of only 182 out of 787 cases, or 23 per cent.; but later, when as the result of riper experience he made his cultures at the bedside and incubated them at once, he succeeded in detecting this micro-organism in the naso-pharyngeal secretion of 46 out of 49 patients, or 94 per cent.

An important point to be borne in mind in this relation is the tendency which the meningococcus shows to disappear from the naso-pharyngeal secretion of the patient as the disease progresses.

Lingelsheim's findings were as follows:—

Day of disease.	No. of specimens examined.	No. positive.	Per cent. positive.
First to fifth day	156	104	66·6
Sixth to tenth day	57	14	24·5
Eleventh to twentieth day ...	62	7	11·2
Twenty-first day and after ...	115	5	4·39

Similar results have been reported by Goodwin and v. Sholly and by Netter and Debré. If in addition it is realised that in a proportion of cases of c.s. fever among troops the patient when first seen by the bacteriologist is in a condition of delirium or coma, as the result of which his naso-pharynx is by no means easy to get at, and the secretion there perhaps either dried up or grossly contaminated by other bacteria, failure to demonstrate the meningococcus in this secretion can be readily understood. Nevertheless, the positive findings already referred to, and the observations made by Captain Martin Flack, R.A.M.C., when in charge of the London District C.S. Fever Laboratory, by Major F. W. Andrewes and Dr. R. G. Canti at St. Bartholomew's, and by others, indicate, in my opinion, that the meningococcus is practically always there at the onset, and is to be found if the investigator has the experience and equipment and is able to devote the necessary time to searching for it. In this relation it may be mentioned that Captain Flack found that it is always advisable to take at least two swabs when examining the naso-pharyngeal secretion of a patient for the meningococcus.

With regard to a considerable proportion of the cases of suspected cerebro-spinal fever at X, to which Major Dorgan refers, I must say that, notwithstanding the careful investigations of Captain Samut, the evidence that they were really infected by the meningococcus is far from complete. The mere presence of a very few diplococci found free or lying in, or on, leucocytes in films of the deposit of a clear cerebro-spinal fluid from a case of transient illness can hardly be accepted *per se* as conclusive bacteriological evidence of cerebro-spinal fever. With every care, the chances of introducing a few sterilised diplococci from the skin of the patient's back must be borne in mind. The positive bacteriological evidence necessary to establish Major Dorgan's ingenious hypothesis that these were really cases of c.s. fever has still to be provided, and even if some of them were abortive cases of that disease, the part they play in its spread has still to be proved.

I am, Sir, yours faithfully,

M. H. GORDON,
Lieutenant-Colonel, R.A.M.C.

Central C.S.F. Laboratory, 12, Caxton-street, S.W. 1,
August 9th, 1918.

WAR DEAFNESS.

To the Editor of THE LANCET.

SIR,—No science has learnt more lessons from the war than medicine. Our knowledge of functional nervous disorders has, for example, greatly increased owing to the frequency of these disorders in soldiers. Old methods of diagnosis have had to be revised, and the results of treatment have steadily improved. The danger of relying on pre-war ideas has nowhere been more obvious, and it has already become necessary to discard many of the views which were prevalent early in the war. Thus, if we relied on the papers published since 1915 by Meige and by Oppenheim, distinguished neurologists as they are, we should still regard the tremors which are so common in shell shock as almost incurable, whereas we now know they respond to psychotherapy almost as rapidly as the more obviously hysterical symptoms. In the same way, if we had accepted the views of Babinski and Froment on "reflex" paralysis and spasm, we should have failed to cure the very common paralyses and contractures of the hand and foot, which have been proved by the rapid recovery under psychotherapy to be hysterical and not reflex in origin. Since the translation of their book the views of Babinski and Froment on reflex nervous disorders have unfortunately been widely accepted in England, as, for example, by Major Judson S. Bury in his paper in THE LANCET of July 27th, although Captains J. L. M. Symns, W. R. Reynell, and A. W. Gill, Lieutenant S. H. Wilkinson, and I have not yet failed to cure by psycho-

therapy a single one among a very large number of cases presenting all the signs and symptoms of so-called reflex paralysis or contracture.

It is unfortunate that two distinguished aural surgeons, Dr. P. McBride and Dr. A. Logan Turner, should have been led by their pre-war experience to write such a pessimistic article on "War Deafness" as that which appeared in THE LANCET of July 20th. If we had believed, like them, that the majority of cases of concussion-deafness are organic in origin, and are consequently incurable, or at the best can only improve slightly, we should never have attempted psychotherapy, whereas in our experience many are completely curable by re-education and suggestion, and very few are incapable of some improvement by the methods which have been devised as a result of war experience. Our results are identical with those obtained by Gordon Wilson and Yealland in England and Roussy and Lhermitte in France. My own "opportunities of studying ear diseases" before the war were fortunately nil, and I was therefore able to face the problem of war deafness with an unprejudiced mind. As it is obvious that suggestion cannot prevent the occurrence of nystagmus on testing the vestibular reaction by rotation or cold water, the loss of this reaction after concussion proves that some organic change has occurred in the internal ear, and that any deafness present is likely to be at least in part organic in origin. On the other hand, total deafness caused by concussion, if associated with a normal reaction, is probably hysterical and due to suggestion, as it is very unlikely that the cochlea should be so damaged that complete deafness results without the adjacent semicircular canals being affected. In cases of incomplete deafness the sign is of less value, but we have acted on the principle that whereas *all* cases of deafness following concussion should be treated by psychotherapy—in the hope that it may be at least in part functional, like the frequently associated mutism, blindness, tremor, or paralysis—we expect to obtain the best results; and we persevere with our treatment for a longer period, when the reactions are normal and definite evidence of organic injury is absent. Our results certainly justify our methods, as we have produced more or less improvement in almost every case and have cured men who have been totally deaf for many months, sometimes after they had been told by distinguished aurists that they could never recover from their "nerve deafness." In contrast to this, Dr. McBride and Dr. Logan Turner appear to have only seen improvement in one case, and in that case it appears to have occurred spontaneously, as it is hardly conceivable that any good could have resulted from the use of pilocarpin, which certainly stimulates the secretion of glands, but has never been proved to stimulate the special senses.

Dr. McBride and Dr. Logan Turner believe that "very grave injustice might be done" by regarding deafness as probably hysterical when the vestibular reactions are normal; we, on the contrary, regard it as most unfair to one's soldier patients to be so prejudiced by pre-war experience that the possibility of functional origin is not considered, the patient being consequently deprived of the chance of cure by psychotherapy. I should regard Case 2 in Group C and Case 1 in Group D as almost certainly hysterical, and curable within a few days and possibly within a few minutes, whereas the authors state that because there is a history of head injury they could exclude all question of functional trouble "with reasonable certainty." The patients therefore remained untreated and will doubtless remain deaf for the rest of their lives, as being told by a distinguished specialist that the trouble is incurable, their disability, which was originally caused by auto-suggestion, would become perpetuated by hetero-suggestion, and the chance of cure by psychotherapy would be enormously reduced.

I am, Sir, yours faithfully,

ARTHUR F. HURST.

Seale Hayne Military Hospital, Newton Abbot, July 28th, 1918.

TREATMENT OF WAR NEUROSES.

To the Editor of THE LANCET.

SIR,—Upon the rapidity of their results as to the removal of hysterical symptoms and on the sensible form of suggestion which they have evolved, Major A. F. Hurst and Captain J. L. M. Symns are to be congratulated. It would greatly enhance the value of their contribution to THE LANCET of August 3rd if they could speak with more definition as to the permanence of the "cures" they mention, and would publish statistics as to the state of their patients six months and one year after "cure." The fact that there are many thousands (30 or 40 I believe) of pensioners, many of them drawing full pensions, under the control of the Special Medical Board, accentuates the necessity of not only removing hysterical symptoms, but of also confirming the cure of these men straight away, before any relapse has occurred.

I have suggested to the medical authorities of the Navy and Army that many, if not all, men who have suffered from war neuroses should be sent, after treatment at a neurological centre, but before discharge to the country, under the auspices of the Country Host Institution, so that they may do outdoor work in the fields and gardens, in conditions half-way between the complete control of a hospital and the sentimentality, worry, and responsibility of their own homes. The Director-General of the Medical Department of the Navy at once accepted the suggestion and some 30 undischarged sailors have already been sent off and are making very satisfactory progress; the Director-General, A.M.S., has not yet informed me whether he intends to fall in with my proposal or not.

I rejoice to find that Major Hurst and Captain Symns agree with my very strong conviction that none of these functional nerve cases should be treated in London, subject as it is to air-raids; all hospitals dealing with such cases should at once be transferred to the country.

The ideal treatment for war hysteria is, I hold: (1) removal of symptoms, &c., by such methods as Major Hurst and Captain Symns use; (2) a three months' course of Country Host convalescent treatment to strengthen the men, re-educate them in the habit of work, and thus confirm the cure effected at the neurological centre. Neurasthenic (nervous debility) cases can with advantage be sent direct to the country for convalescence, thus obviating the necessity of their occupying valuable hospital accommodation.

I am, Sir, yours faithfully,

August 3rd, 1918. THOMAS LUMSDEN.

INFANT MORTALITY AND MOTHERCRAFT.

To the Editor of THE LANCET.

SIR,—One would hardly imagine, on reading Dr. W. A. Brend's letter published in your issue of July 27th in reply to my article of July 6th, that the main point at issue between us is (to quote from his own report)—

"That the excess (of infant mortality) in industrial towns, the centres of large cities, and mining areas is due to some factor or factors, of which possibly *the most important is a polluted state of the atmosphere.*"

He says it probably is; I say it is not. Instead of addressing himself to this issue he concludes his letter of the 27th by writing:—

"I am of opinion that the main cause of excessive infant deaths, as of tuberculosis, malnutrition of school children, and other evils, is overcrowding of houses, congestion of streets, and the absence of large and sufficient open spaces."

Cannot Dr. Brend see that these things mean far more than a polluted atmosphere, and that, under such conditions, mothercraft, and all that it implies, becomes of paramount importance?

He is wrong in stating that my main criticisms of his report are two in number—viz., that he has endeavoured to eliminate poverty and under-estimated the value of mothercraft! My article was an attempt to do much more than that; it was an attack all along the line against his method of proof by a process of exclusion—a process which, I hold, was singularly illogical and unconvincing, and in certain directions, to be candid, not quite fair or judicial.

If Dr. Brend will get into contact with the working-class inhabitants of any large town, he will soon find for himself that far the larger amount of the excess infant mortality in that town does occur amongst the children of the unskilled and casual workers and others of the same social station. That they are living under the worst housing conditions I grant, but it is also amongst that class that the worst housewifery and mothercraft exists.

He further says that nowhere has he suggested that maternity and infant welfare centres should be incontinently scrapped. I never said he had; but that would be the

logical outcome of his report, if accepted, and I suggested that that was the question we who are interested in these institutions must put to ourselves.

I am obliged to Dr. Ronald Carter for his support. From his own long and practical experience he appreciates, I know, the real difficulty of compiling thoroughly satisfactory mortality tables for consultation infants. It could be more satisfactorily done by medical officers of health than by medical officers to consultations, most of whom in times past have not been directly connected with Public Health departments, nor, therefore, had the facilities for the extended inquiry which such tables imply.

I hope, however, in due time to be in a position to publish some statistics dealing with this point.

I am, Sir, yours faithfully,

H. W. POOLER, M.B.,
Medical Superintendent, Derbyshire County Infant Welfare Centres.

Stonebroom, Alfreton, August 11th, 1918.

THE LATE MR. W. MORLEY WILLIS, OF NOTTINGHAM.

To the Editor of THE LANCET.

SIR,—We should like to record the loss to British surgery in the death of that brilliant young surgeon, Mr. W. Morley Willis, F.R.C.S. Eng. Clear-headed, indefatigable, and self-confident, he was bound, if he had lived, to take a place in the first rank of his profession; his death seems to have escaped public notice.

He was a native of Bristol and was educated at Taunton Grammar School. A business career had been arranged for him, and for some time to meet the wishes of his relatives he made an effort in this direction, although from boyhood his ambition was to be a surgeon. But with his twenty-first year he brushed aside all other considerations and commenced the study of medicine at University College, Bristol. When he qualified in 1895 he continued his surgical studies at St. Bartholomew's Hospital, London, taking the Fellowship of the Royal College of Surgeons of England in the following year.

Commencing practice in Nottingham in 1897, he joined the surgical staff of the Children's Hospital, and in 1901 he was appointed assistant surgeon to the Nottingham General Hospital. Soon after this he abandoned general practice and confined himself entirely to surgery. In addition to the public work which these appointments entailed, Mr. Willis's heavy duties in connexion with various military hospitals made his life latterly a very full one. Two months ago, while well, cheerful, and full of work and vigour, he was struck down with fatal illness, which he faced with extraordinary courage and pluck. Mr. Willis was not only a brilliant surgeon and skilful diagnostician, but a kindly and courteous colleague, always ready to give help and advice in difficult cases and eager to assist the younger men in any way he could. He has been greatly missed by his colleagues and by his patients, who loved him for his cheery optimism and charming manner. Mr. Willis leaves a widow and two daughters.—We are, Sir, yours faithfully,

JOHN MACKIE, L.R.C.P. Edin.,
H. BELL TAWSE, F.R.C.S. Eng.,
Assistant Surgeon to the Nottingham General Hospital.

August 9th, 1918.

COLONIES IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—I note in your issue for August 3rd two articles on the above subject. To me it appears the eternal mistake of not knowing the beginnings of tuberculosis is being made. In my experience very few early cases of pulmonary tuberculosis require more than three months in a sanatorium, and those that require more would seldom be better for being made to work. Colonies are only suitable for chronic cases—that is, cases which have not been treated properly when exhibiting symptoms of activity. Whether the expense involved in treating cases of this kind for prolonged periods is justified is more than open to doubt. That it is impossible to treat tuberculosis in the early stage at dispensaries would seem obvious to anyone who has had to deal with this disease; some might at great risk to themselves be treated at home, but never by walking about. That early cases require as long as 18 months must also usually be an error, and it seems probable that the truth must lie between these two extremes. I should like to suggest to physicians to take a previous and careful history of the health of all the cases they regard as early, and in the light of the new facts re-grade their cases and try to avoid allowing their future patients to become chronic.

I am, Sir, yours faithfully,

EDWARD E. PREST.

Ayrshire Sanatorium, New Cumnock, August 7th, 1918.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

Surgeons (Reserve) to be Staff-Surgeons (Reserve): J. P. Berry, C. F. Bainbridge, S. N. McBean. To be temporary Surgeons: W. E. M. Wardill, V. T. Smith, S. C. Mitchell, S. Acheson.

The following appointments have been made:—Surgeons (temporary): H. Whyte to *Centurion*; B. F. Niblock to Chatham Hospital; J. D. Arthur to Plymouth Hospital; and W. Edgar to Haslar Hospital.

ARMY MEDICAL SERVICE.

The undermentioned temporary appointments are made at the War Office: Dep. Asst. Dir.-Gens.: Capt. E. F. W. Mackenzie, and to be temporary Major whilst so employed; Temp. Major S. Fleming.

ROYAL ARMY MEDICAL CORPS.

T. B. Rhodes, late temp. Major, is granted the honorary rank of Major.

M. A. Collins, late temp. Capt., to be temporary Lieutenant-Colonel whilst serving at the Ewell (County of London) War Hospital.

Temporary Captains relinquishing their commissions and are granted the honorary rank of Captain: J. Glaister, on account of ill-health contracted on active service; L. M. Webber, on account of ill-health caused by wounds.

Temporary Lieutenants to be temporary Captains: R. T. St. J. Brooks, D. G. Halsted, H. E. Gray, J. L. McCann, E. H. R. Harries, W. W. Walker, A. M. Hewat, (Acting Major) D. Burrows, J. A. Loughridge, J. A. Clarke, H. M. Raven, R. M. Menzies, W. A. Mahon, R. McN. Wilson, G. M. Coope, A. F. Sanderson, A. M. Jones, A. Rhodes, M. Hocken, N. K. Foster, J. C. Middleton, A. Allison, C. W. Ewing, R. Wade, E. D. W. Reid, C. R. Wilkins, K. H. Bennett, F. H. Flack, S. S. M. Wood, (Acting Major) R. G. Oram, G. J. Eady, D. Martin, H. Sinson, J. Hunter, A. Brownlie, J. H. Thompson, J. E. R. McDonagh, L. G. Leonard, D. A. Stewart, C. Garner, J. A. Brown, T. N. Wilthew, W. Murray, F. Butler, A. White, J. D. Kenyon, W. J. McFeat, T. D. Graham, H. J. van Praagh, R. N. Berman, A. Bradshaw, A. G. Craib, D. M. McGillivray, A. D. Yule, W. Gorrie, W. Boyd, T. W. Bayne, G. B. Charnock, R. Parry, G. B. Warburton, G. Newstead, W. Angus, J. K. Willis, F. B. O'Dowd, G. H. Mead, R. J. Reynolds, J. H. Sutcliffe, H. H. Jenkins, J. K. Hamilton, G. A. Rorie, A. S. Campbell, A. T. MacKenzie, S. Bree, S. G. Corner, D. A. Dewar, W. J. D. Bromley, A. Davies, R. Davidson, J. W. Simon, K. R. C. Hallowes, F. D. Parbury, S. L. O. Young, N. McC. Hutchison, F. D. Nicholson, W. L. English, E. Banks, A. S. M. Palmer, E. E. Cassady, L. D. Stamp, H. P. Dawson, A. M. Laurie, J. Donaldson, H. M. Reeve, M. F. Emrys-Jones, W. G. Riley, A. Morton, A. Barker, D. Purdie, J. F. Findlay, H. J. Beddow, R. L. Haines, E. F. Thomas, A. D. Crofts, H. J. Rae, G. C. B. Miéville, C. W. Hutt, R. S. Roper, P. W. Stewart, F. F. Laidlaw, A. V. Ledger, N. C. Rogers, H. Snape, K. S. Melvin, J. R. Cameron, T. Miller, A. Robertson, P. E. Carroll, M. T. D. McMurrich, A. Boyle, E. E. Atkin, J. Fletcher.

Temp. Hon. Lieut. A. H. Good to be temporary Honorary Captain.

Temp. Lieut. Michael J. MacCarthy relinquishes his commission.

TERRITORIAL FORCE.

Major (temp. Col.) A. Milne-Thomson relinquishes his temporary rank on vacating appointment as Assistant Director of Medical Services, and is restored to the establishment.

Major (Bt. Lieut.-Col.) T. D. Acland remains seconded whilst holding a temporary commission in the R.A.M.C.

Capt. A. N. McGregor is restored to the establishment.

Capt. J. Allan to be Major.

Capt. A. E. Woodhead is seconded for duty.

Capt. (acting Major) H. Henry relinquishes his acting rank.

Capt. A. McLean is seconded for duty with General Hospital.

R. B. Driscoll and S. Shaw, R.A.M.C., to be Lieutenants.

ROYAL AIR FORCE.

Medical Branch.—A. P. Woolright (late Captain, R.A.M.C.) and W. G. West are granted temporary commissions as Captains.

P. A Dormer, R. W. Stephenson, G. F. H. Bloom, H. B. B. Greene are granted temporary commissions as Lieutenants.

Dental Branch.—W. C. Murray (late Dental Surgeon, R.N.V.R.) is granted a temporary commission as Captain and to be temporary Major whilst specially employed.

DEATH OF MR. B. G. DERRY, L.R.C.P., M.R.C.S.—Mr. Bartholomew Gidley Derry died on August 8th, at his residence at Bodmin, from the effects of a carriage accident. Mr. Derry, who was in his seventy-second year, had practised in Bodmin for 47 years. He had an extensive practice and he was medical officer of health for the Bodmin (Cornwall) urban district, surgeon to the Civil and Naval Prisons at Bodmin, and also held other appointments in which he earned high respect in Bodmin and the district. He leaves two sons and three daughters.

The War.

THE CASUALTY LIST.

THE following medical officers appear among the casualties announced since our last issue :—

Killed.

Capt. H. R. Partridge, M.C., R.A.M.C., qualified in London in November, 1914, and was attached to the 1st West Riding Field Ambulance in the early part of the following year. The award of the M.C. was recorded in THE LANCET of Oct. 28th, 1916, p. 770.

Reported Missing, now believed Killed.

Capt. W. H. Lloyd received his medical education at the Middlesex Hospital, and qualified in 1915. He became attached to the 3rd London General Hospital in August, 1915, and had been in France since June, 1916.

Died.

Surg. Prob. A. E. Beckwith, R.N.V.R.
Lieut. D. Taylor, R.A.M.C., qualified at Glasgow in July, 1917, and joined the R.A.M.C. quite recently.

Wounded.

Capt. R. Anderson, R.A.M.C., attached Grenadier Guards.
Capt. W. Baxter, R.A.M.C., attached Gordon Highlanders.
Major G. Stiell, R.A.M.C.
Col. T. W. Gibbard, C.B., K.H.S., R.A.M.C.
Capt. E. M. McCaffrey, Australian A.M.C.
Lieut. J. J. Hughes, R.A.M.C., attached N. Staffs Regt.
Capt. A. W. Ritchie, R.A.M.C.
Lieut. J. J. Pickles, R.A.M.C., attached W. Yorks Regt.

Previously reported Missing, now reported Prisoners in German Hands.

Capt. C. R. Crowther, R.A.M.C.
Capt. W. T. P. Meade-King, R.A.M.C.
Capt. G. F. P. Heathcote, M.C., R.A.M.C., attached East Lancs Regiment.
Capt. F. C. H. Bennett, R.A.M.C., attd. Northumberl'd Fus.
Lieut. A. Boyle, R.A.M.C.
Capt. M. S. Esler, R.A.M.C., attached Middlesex Regiment.
Capt. D. D. Gillespie, R.A.M.C.
Lieut. J. W. Jones, R.A.M.C., attached Rifle Brigade.
Lieut. A. M. McCormick, R.A.M.C., attd. Lincs Regiment.
Capt. C. Witts, M.C., R.A.M.C.

MENTIONED IN DESPATCHES.

The names of the following medical officers are mentioned in a despatch by Lieutenant-General Sir J. L. van Deventer, K.C.B., Commanding-in-Chief, British East Africa Force, for distinguished services during the operations from May 30th to December, 1917 :—

Royal Army Medical Corps.—Lt.-Col. (acting Col.) F. E. Gunter, D.S.O.; Capt. W. Fraser; Capt. J. O. Garland; Temp. Lt. J. I. Greig; Capt. A. Hendry; Capt. H. F. Holmden; Temp. Capt. C. R. Howard; Lt.-Col R. H. Humphrey; Maj. G. J. Keane, D.S.O.; Temp. Capt. A. R. Lindsay; Temp. Capt. L. R. P. Marshall; Temp. Capt. J. Miller; Capt. W. Mitchell; Temp. Capt. M. T. Morgan, M.C.; Temp. Capt. A. Moxon; Temp. Capt. W. A. Ryan; Temp. Lt. R. Semple; Capt. H. A. Sutton, M.C.; Temp. Capt. W. B. Walker; Capt. G. A. Williams.

Royal Army Medical Corps (S.R.).—Capt. H. S. A. Alexander; Lt. J. F. C. Braine; Capt. S. J. V. Furlong; Capt. R. L. Impey, M.C.; Lt. R. Lloyd-Jones; Lt. F. C. Logan; Capt. W. A. McLennan; Capt. G. M. Roberts; Capt. A. R. Ross; Lt.-Col. J. McKie, D.S.O.

Indian Medical Service.—Lt.-Col. (Temp. Col.) W. W. Clemesha; Capt. F. W. Hay, attd. Inf.; Capt. T. A. Hughes; Maj. J. Husband; Capt. H. M. Inman; Capt. M. L. C. Irvine; Capt. G. G. Jolly; Capt. W. M. Lupton; Maj. P. L. O'Neill.

Indian Subordinate Medical Department.—2nd Cl. Asst. Surg. A. Bayley-de-Castro; Asst. Surg. (Hon. Lt.) J. A. F. Harvey; 1st Cl. Asst. Surg. E. D. Shave; 2nd Cl. Sub-Asst. Surg. Bhag Singh; 2nd Cl. Sub-Asst. Surg. Gordhandas Jethabhai Desai; 2nd Cl. Sub-Asst. Surg. Govind Ramchandra Upalekar; 2nd Cl. Sub-Asst. Surg. Hari Singh; 1st Cl. Sub-Asst. Surg. Kashi-Nath Ram-Chandra Kalamkar; 1st Cl. Sub-Asst. Surg. Mihrab Khan; 2nd Cl. Sub Asst. Surg. Muhammad Kusain; 1st Cl. Sub.-Asst. Surg. Muhammad Riazuddin; 3rd Cl. Sub-Asst. Surg. Mukand Ram; 1st Cl. Sub-Asst. Surg. Nand Lal; 1st Cl. Sub-Asst. Surg. Nur Muhammad; 2nd Cl. Sub-Asst. Surg. Shambhu Nath; 1st Cl. Sub-Asst. Surg. Varyam Singh.

South African Medical Corps.—Capt. A. J. Ballantyne; Temp. Capt. C. P. Bligh-Wall; Capt. H. J. Brady; Maj. C. M. Brothers; Capt. R. D. A. Douglas; Maj. (temp. Lt.-Col.) W. V. Field; Maj. (temp. Lt.-Col.) W. Gilbert; Lt.-Col. R. L. Girdwood, D.S.O.; Capt. S. J. O'L. Greensill; Capt. D. Henderson; Capt. J. E. Hurworth; Maj. T. J. W. A. Johnston; Maj. A. Liebaert; Capt. S. MacPherson; Maj. A. D. McKenzie; Capt. H. V. Potter; Capt. W. Shanks; Lt. N. E. Thomson; Capt. G. B. Wilkinson.

East African Medical Service.—Temp. Capt. N. P. Jewell, M.C.; Capt. C. G. Tomblings, African Native Medical Corps; Lt. R. McGeorge; Temp. Capt. J. M Mackinnon attd. K.A.R.

West African Medical Service.—Temp. Capt. B. J. Courtney; Capt. R. F. Williams, M.C., attd. Gold Coast Regt.

Uganda Medical Service.—Temp. Capt. A. H. Owen; Maj. C. A. Wiggins.

Northern Rhodesia Medical Service.—Capt. J. A. Chisholm; Capt. and Temp. Surg. E. G. Storrs, M.C.

Nyasaland Field Force Medical Service.—Temp. Capt. A. G. Eldred; Temp. Capt. W. C. Wigan.

The names of the following medical officers are mentioned in a despatch dealing with the engagement between the torpedo-boat destroyers *Mary Rose* and *Strongbow* and three German light cruisers which attacked a convoy on Oct. 17th, 1917 :—

Surg.-Prob. I. C. C. Barclay, R.N.V.R. (killed in action); Surg. J. P. Shorten, D.S.C., R.N.

OFFICERS OF C.A.M.C. ON H.M.H.S. "LLANDOVERY CASTLE" TORPEDOED.

The following is a brief account of the five officers of the Canadian Army Medical Corps missing, believed drowned, through the torpedoing on June 27th of H.M.H.S. *Llandovery Castle* :—

Lieutenant-Colonel THOMAS HOWARD MACDONALD, who was in command of the ship, was 40 years of age, and a native of Port Mulgrave, Nova Scotia, and graduated at Bellevue Hospital Medical College, N.Y., in 1900. Before the war he was in practice at Port Hawkesbury, N.S., and an active member of the Canadian Militia, in which he held the rank of major. He came overseas in December, 1915, and after various hospital appointments became president of the standing medical board, London area, later serving with a labour battalion in France.

Major GUSTAVUS MITCHELL DAVIS, who was 43 years of age, was a native of York, Ontario, graduating in medicine from the University of Toronto in 1901, and practising at Welland, Ont. He came overseas with the first Canadian contingent in September, 1914. After taking part in the battle of Festubert he was appointed M.O. upon the hospital ship *Letitia*, and when this ship was wrecked on the coast of Nova Scotia in August, 1917, rendered distinguished service in the care and rescue of patients.

Captain ARTHUR VINCENT LEONARD, who was 37 years of age, was a native of Warkmouth, Ontario, graduating in 1911 at the University of Toronto, where he was a prominent athlete. He came overseas in September, 1915, and after serving as M.O. of various units at the front he was appointed to H.M.H.S. *Araguaya*.

Major WILLIAM JAMES ENRIGHT, who was 44 years of age, was a native of Port Daniel, P.Q., graduating in medicine at Laval University in 1897. He served in Canada on the staff of the Quebec Military Hospital before coming overseas. While serving as M.O. in France he was wounded on Sept. 29th, 1915, and evacuated to England, and returned to Canada for three months' sick leave. Later, in charge of embarkation, his name was brought to the notice of the Secretary of State for War. Finally he had been serving as registrar and adjutant of No. 8 Canadian General Hospital.

Captain GEORGE LUTHER SILLS, who was 30 years of age, was a native of Tweed, Ontario. While a student in medicine at Kingston University he joined the C.A.M.C. as a private, serving overseas for a year with the 5th Stationary Hospital. Returning to Canada he graduated in November, 1916.

A QUESTION OF EXEMPTION.

After a conjoined meeting of the Executives of the Edinburgh and Leith Division of the British Medical Association and of the Scottish Medical Guild the following question was sent to Sir Auckland C. Geddes and Sir James Galloway :—

"In the event of a medical man having been granted exemption from ordinary military service on occupational grounds, and called upon to undertake either military or civil work, and he has objections to the work he has been called upon to undertake, will he have the right to appeal to the Medical Tribunal?"

The reply received from Sir James Galloway states that the practitioner has no legal right to a hearing by the Medical Tribunal as such, but that both the Central Professional Committees have arranged that in such circumstances the practitioner would receive a personal hearing, at which his objections to the particular form of service allotted to him would receive every consideration.

THE MEDICAL SERVICE IN THE EAST AFRICAN CAMPAIGN.

—In reply to a question by Commander N. Craig, Mr. Macpherson last week informed the House of Commons that a report by Colonel Pyke and Lieutenant-Colonel Balfour, R.A.M.C., on the Army Medical Service in Africa had been received in May. The report was of a personal and highly confidential nature, and could therefore not be laid upon the table, and effective action had been taken upon it.

OBITUARY OF THE WAR.

FRANCIS METCALFE, M.B., B.S. DURH.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain F. Metcalfe, who died on July 10th, was 26 years of age and a medical graduate of the University of Durham. Qualifying in June, 1914, he joined the 1st Northumberland Field Ambulance in the following August. He went to France with his unit in April, 1915, remaining there until he was invalided home in September, 1916, with myelogenous leukæmia. After treatment in the 1st Northern General Hospital he made a seemingly good recovery, and after several months at Catterick returned, at his own request, to France in August, 1917. He went through the March retreat, with all its attendant physical and mental strain, and the leukæmia regained its hold upon him. This time he did not react to treatment, and death occurred after a period of severe dyspnœa in the Framlingham House Hospital for Officers, Newcastle-upon-Tyne. During his college days Captain Metcalfe was good at all field sports and was the heavy-weight champion boxer. As a student he was conscientious in his work, taking good places in class. Retiring in manner and with no outward display, he was felt by his teachers to have qualities which only required time and opportunity to develop. Captain Metcalfe was an only son.

KEYSER ATKIN, B.A. CAMB., M.R.C.S. ENG.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain K. Atkin, who died of wounds on June 6th, was only son of Mr. P. W. Atkin, stipendiary magistrate at Salford. He was educated at Mostyn House Preparatory School (where he was head of the school and chief of the cadet corps), at Mill Hill, and Jesus College, Cambridge. On the outbreak of war he applied for a commission, but was told to continue his medical studies and become qualified. This he did in July, 1916, after having acted, when still a student, as house physician at St. Mary's Hospital, and house surgeon at the Royal Infirmary, Manchester. He then at once obtained a commission in the R.A.M.C. attached to the South Staffs Regiment. In September, 1917, when hurrying to the relief of men buried by a shell, he was taken prisoner of war, being released five months later. During his short stay at home he took a special course of dentistry in order to be of greater service to the men on his return to France. While at his dressing-station he received wounds from which he died the same day. Captain Atkin's headmaster writes of him as utterly straight and conscientious, and this reputation remained with him through life. At Mill Hill "he proved himself a boy of great character and stern resolve for right, who made his influence felt for long after he had left." He won distinction as an athlete, rowing in his college boat three times at Henley; rowing was an hereditary accomplishment with him, for his father rowed for Cambridge for three consecutive years. He was also one of the best miniature shots in England, winning the Lord Roberts gold medal; and was second in the Public Schools' boxing competition at Aldershot. At college he was the first man who ever passed the whole of the Second M.B. before taking his B.A. degree, and his teachers predicted for him a splendid future.

JAMES RANDOLPH GYLLENCREUTZ, M.R.C.S. ENG.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain J. R. Gyllencreutz, whose death from drowning is now presumed, was in medical command of H.M.H.S. *Salta* mined in the Channel during April of last year. He studied at St. Thomas's Hospital Medical School, taking the conjoint qualification in 1908, and thereafter holding house appointments at the Royal Hospital, Portsmouth, and the Brentford Infirmary. He was then for some years ship surgeon on the Royal Mail line. When war broke out he was senior assistant at the Wandsworth Infirmary. Resigning at once to take a commission in the R. A. M. C., after varied work he went to the Dardanelles in charge of a hospital ship. He went down with his ship, but was picked up by a rescuing vessel which was itself sunk soon after. Captain Gyllencreutz's friends write of his cheerful and breezy disposition. In his own circle he was popular as an amateur actor.

ROBERT NEILSON WALLACE, M.B., CH.B. EDIN.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain R. N. Wallace, who died on July 5th in command of a military hospital, was 35 years old and son of the late Dr. R. S. Wallace, of Edinburgh. Graduating in medicine at the University of his native city, he held resident appointments at the Bradford Infirmary and the Manchester Children's Hospital before settling in Edinburgh, where he became clinical assistant to the Ear and Throat Department of the Royal Infirmary. For many years he held a Territorial commission in the R. A. M. C., being attached to the 6th Battalion of the Royal Scots. When called up for permanent duty he qualified as a gas officer and was put in command of the 50th Stationary Hospital at Colchester. While there he took influenza and succumbed to a secondary pneumonia. Captain Wallace was a tall and striking figure. He was widely travelled and possessed of artistic and literary gifts, which accentuate the loss felt by his many personal friends now he is gone.

THE BELL FUND.—Dr. S. A. Kinnier Wilson asks us to acknowledge donations to the Dr. J. H. Bell Fund from Sir Hugh Rigby (£10 10*s.*), Dr. David Dinwoodie (£1 1*s.*), Lieut.-Colonel E. Farquhar Buzzard (£5 5*s.*), and from Captain Ralph R. Watts, R.A.M.C. (£1 1*s.*). Subscriptions should be sent to Dr. Wilson at 14, Harley-street, London, W. 1.

Medical News.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.—The following awards of scholarships tenable at the Medical School have been made recently:—St. Dunstan's Medical Exhibition: £60 a year for five years, Miss M. E. Reynolds, North London Collegiate School; £40 a year for five years, Miss M. E. Howard, St. Paul's Girls' School. Isabel Thorne Scholarship, £30, Miss E. A. Perrott, Bromley High School. Sir Owen Roberts Memorial Scholarship, £75 a year for four years, Miss L. G. Iliff, London School of Medicine for Women. Mabel Sharman Crawford Scholarship, £20 a year for four years, Miss D. N. L. Leverkus, London School of Medicine for Women. Agnes Guthrie Dental Bursary, £50, Miss Petronelle Jago, Besheben High School, Brondesbury. Ellen Walker Bursary, £25 a year for two years, Miss G. M. Watkinson, London School of Medicine for Women. Fanny Butler Scholarship, £14 10s. a year for four years, Miss A. D. Symons, London School of Medicine for Women.

POST-GRADUATE COLLEGE, WEST LONDON HOSPITAL.—During next week clinics will be held each week-day at 2 P.M., Wednesday, Friday, and Saturday also at 10 A.M.

DEATH OF DR. R. W. SPENCE.—Dr. R. W. Spence, Government medical officer, British East Africa, has died at Nakuru, after an illness extending over ten weeks. Dr. Spence was an active and very capable officer, and was universally trusted in the large district of Nakuru, where he had been stationed since his appointment to the Protectorate Government Medical Service in August, 1913. His death is widely regretted.

LITERARY INTELLIGENCE.—The Oxford University Press announces the forthcoming issue of the first number of "Neurological Studies" from the Seale Hayne Military Hospital, Newton Abbot, edited by Major A. F. Hurst, with the assistance of Captain J. L. M. Symns, Captain W. R. Reynell, and Lieutenant S. H. Wilkinson.

PRESENTATION TO MR. ROBERT BURGESS, L.R.C.P. & S. EDIN., J.P.—Mr. Robert Burgess, who is dispensary medical officer of Coagh Dispensary District, co. Tyrone, and who has been president for a period of 25 years of the Coagh Coöperative Dairy Society, was recently presented with a handsome tea and coffee service by the shareholders of Albany, Coagh, and Curglasson Creameries, and other friends. Mr. Burgess has been largely responsible for the establishment of the creameries in his district of county Tyrone; the Central Coagh Creamery was the first started in the North of Ireland, and did much to re-establish the reputation of Irish butter.

METROPOLITAN HOSPITAL SUNDAY FUND.—At a Council meeting of the Metropolitan Hospital Sunday Fund held at the Mansion House on August 9th, under the presidency of Sir Ernest Tritton, it was announced that the Fund had reached the total of £85,652. The number of participating institutions was 238. The year 1918, said the chairman, was a record one in regard to the amount available for distribution, and this was largely due to a gift of £5000 from the American Red Cross Society. Ministers of religion had carried their appeals into the homes of both rich and poor, either by letters or house-to-house visitation, with very gratifying results, and in one parish £76 had been thus raised in pence alone. Among the largest recipients are the London Hospital £10,217, Guy's Hospital £3467, Middlesex Hospital and Convalescent Home £3730, and St. George's Hospital £3235.

QUEEN'S UNIVERSITY, BELFAST.—At a recent meeting of the Senate it was decided that, for next session, the department of anatomy (vacant through Professor Symington's resignation) should be placed under the direction of Dr. P. T. Crymble, with Dr. R. J. McConnell and Dr. Margaret Purce as demonstrators. It was also arranged to appoint a committee, consisting of the curators and the medical members of the Senate, to confer with the medical faculty in reference to the question of rearranging the work of the Department of Anatomy and to report to the Senate at a later date.—The following have been awarded scholarships in the Faculty of Medicine:—First Medical Examination: W. J. Frackelton, £40; John Beattie, £30; Cecil A. Calvert, £20; and Olive M. Pedlow, £15. Second Medical Examination: S. J. Andrews and J. T. Lewis, £40 each; Eileen M. Hickey, £30; C. H. G. MacAfee, £20; and William S. Gibson, £15. Third Medical Examination: Isaac Eban, Henry Harris, Joseph Meban, and Phillip F. Mooney. Final Medical Examination: William J. Lytle and Henry F. Macauley, medicine, £30 each; Samuel E. Duff and Mary E. Irwin, midwifery, £30 each; Chas. A. Whitfield, surgery, £30; and Charles A. Whitfield, general prize, £20.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Parliamentary Session.

BOTH Houses of Parliament have adjourned until Tuesday, Oct. 15th.

Royal Assent.

Amongst the measures which received the Royal Assent before the adjournment were the Education Act, the Maternity and Child Welfare Act, and the Asylums and Certified Institutions (Officers' Pensions) Act.

Midwives Bill.

Mr. HAYES FISHER, President of the Local Government Board, has presented in the House of Commons a Bill to amend the Midwives Act, 1902. It was read a first time. The intention is to proceed with it when the House resumes after the autumn adjournment. A Midwives Bill passed through the House of Lords this session, but owing to certain technical obstacles relating to privilege it was not found possible to bring it before the House of Commons. Mr. HAYES FISHER has therefore introduced his measure in substitution for it.

HOUSE OF COMMONS.

WEDNESDAY, AUGUST 7TH.

Indian Medical Service and Children's Allowances.

Answering Colonel YATE, Mr. MONTAGU (Secretary for India) said: Proposals for the grant of children's allowances to officers of the Indian Army, Indian Army Reserve, and Indian Medical Service have been received from the Government of India and are under reference to the War Office. I have proposed that the allowances should be granted with retrospective effect to Oct. 1st, 1917, the date of the commencement of the allowance for British service officers.

Promotion of R.A.M.C. Officers (Territorial).

Sir B. FALLE asked the Under Secretary for War whether he could give any date or information when the promotion of the field officers, Royal Army Medical Corps, Territorial and Volunteer, was likely to take place, or as to the retirement of such officers in default of such promotion.—Mr. MACPHERSON replied: I presume my honourable and gallant friend is referring to the promotions in accordance with the instructions issued recently regarding the introduction of a general seniority list for officers of the Royal Army Medical Corps (Territorial Force). The promotion of the officers of the Territorial Force mentioned will take place as soon as possible after the receipt of the recommendations from the various theatres of war in which these officers are serving. Officers not selected for promotion will not be retired on that account.

Sir B. FALLE: Does that apply to those serving at home?—Mr. MACPHERSON: I presume so.

Asylum Treatment of Lunatic Soldiers.

Replying to Sir WATSON RUTHERFORD, Mr. HODGE (Minister of Pensions) wrote: Men of the Army and Navy whose mental condition has become impaired owing to their service, and who are admitted to asylums, are not separately housed, but special arrangements are made for their maintenance. They are not chargeable to the rates and they do not rank as paupers. Evidence as to mental attack anterior to military service is clearly relevant in determining whether or not the disability is due to service. It is not considered that the provision of separate institutions is practicable, nor is it desirable having regard to the expediency of placing the patients near their friends.

URBAN VITAL STATISTICS.

(Week ended August 10th, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality was 10·4, against 13·1 and 12·1 per 1000 in the two preceding weeks. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 10·5, or 0·9 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 4·4 in Hornsey, 5·1 in Southend-on-Sea, and 5·3 in Acton, to 17·9 in Gateshead, 18·5 in Rotherham, and 20·3 in Aberdare. The principal epidemic diseases caused 237 deaths, which corresponded to an annual rate of 0·8 per 1000, and included 97 from infantile diarrhœa, 54 from measles, 39 from whooping-cough, 29 from diphtheria, 13 from scarlet fever, and 5 from enteric fever. The deaths from measles and from whooping-cough were the lowest recorded in any week of the current year. The deaths from infantile diarrhœa, which had risen from 34 to 74 in the four preceding weeks, further rose to 97 last week. The 746 cases of scarlet fever and 904 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 20 and 23 below the respective numbers remaining at the end of the previous week. The 810 deaths from all causes in London included 21 from influenza, against 192, 86, and 38 in the three preceding weeks. The causes of 45 deaths in the 96 towns were uncertified, and included 8 each in Birmingham and in Liverpool, and 6 in Gateshead.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 11·8, against 14·2 and 13·1 per 1000 in the two preceding weeks. The 265 deaths in Glasgow corresponded to an annual rate of 12·4 per 1000, and included 17 from infantile diarrhœa, 6 from whooping-cough, 4 from measles, 2 from diphtheria, and 1 from enteric fever. The 67 deaths in Edinburgh were equal to an annual rate of 10·5 per 1000, and included 1 each from whooping-cough and from infantile diarrhœa.

Irish Towns.—The 117 deaths in Dublin corresponded to an annual rate of 15·3 per 1000, and included 11 from infantile diarrhœa, 2 from measles, and 2 from whooping-cough. The 102 deaths in Belfast were equal to an annual rate of 13·5 per 1000, and included 9 from infantile diarrhœa, 2 from whooping-cough, and 1 from measles.

Appointments.

ASHER, M., L.R.C.S. Irel., has been appointed Assistant County Medical Officer to the Southampton County Council.

AZIZ, A., M.B., Ch.B. Edin., Assistant School and Tuberculosis Medical Officer for Wigan.

BUTTERFIELD, F., M.B. Lond., Temporary Assistant Tuberculosis Officer to the Manchester Corporation.

HOA HING, MARTHA H., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., House Surgeon at the Alexandra Hospital for Children, Brighton.

PAUL, E. W., M.R.C.S. Eng., Certifying Surgeon under the Factory and Workshop Acts for the East Nottingham District of the county of Nottingham.

TAYLOR, ALICE, L.R.C.P. & S. Irel., L.M., Assistant County Medical Officer to the Southampton County Council.

WILSON, J. M., M.B., Ch.B. Aberd., Certifying Surgeon under the Factory and Workshop Acts for the Aberdare District of the county of Glamorgan.

Vacancies.

For further information refer to the advertisement columns.

Birmingham Education Committee.—Asst. School M.O. £300.
Blackburn County Borough.—Two Asst. M.O.H. £500.
Bramcote Sanatorium, Nuneaton.—Res. M.O. £300.
Bristol Royal Infirmary.—H.P. and H.S. £120
Bristol University.—Demonstrator in Physiology.
Brook War Hospital, Woolwich, S.E.—Res. M.O. £1 per diem.
Carlisle City, Maternity and Child Welfare.—Asst. M.O. £400.
Cheltenham Eye, Ear, and Throat Free Hospital.—Asst. S. £400.
Derbyshire County Council.—Asst. M.O. £400.
Dorset County Council.—Temp. Female Asst. M.O. £350.
Erdington Infirmary and House.—Asst. M.O. £8 8s. per wk.
Glasgow, Govan District Asylum, Cardonald.—Sen. Asst. M.O. 6 or 7 gs. weekly. Also Locum.
Liverpool, Toxteth Park Guardians.—Asst. Res. M.O. £300.
London County Mental Hospital, Bexley, Kent.—Asst. M.O. 7 gs. wk.
Manchester County Asylum, Prestwich.—L.T. £7 7s. per week.
Manchester Royal Eye Hospital.—Sen. H.S. £120.

Nottingham General Hospital.—Two Female H.S. £250.
Notts Education Committee.—Asst. Sch. M.O. £400.
Queen Mary's Hospital, Stratford.—H.S.
Rochdale Infirmary and Dispensary.—Jun. H.S. £150.
Sheffield Royal Infirmary.—Res. S.O. £200. Also H.S. £150.
Stoke-on-Trent County Borough.—Asst. Tuberc. O. £400.
Tottenham Urban District Council.—M.O. for Maternity and Child Welfare Centre.
Walsall General Hospital.—Female H.S. and Anæs. £175.
Westmorland Consumption Sanatorium.—Asst. M.O. £200 to £250.
Whitehaven and West Cumberland Infirmary.—Res. H.S. £150 to £180.

Births, Marriages, and Deaths.

BIRTHS.

BREWERTON.—On August 6th, at Harley-street, the wife of Elmore Brewerton, F.R.C.S., of a son.

HUNT.—On August 10th, at Cahermoyle, South Farnborough, Hants, the wife of Ernest Rivaz Hunt, M.D., M.R.C.P., Temp. Capt., R.A.M.C., of a daughter.

MCKEE.—On July 25th, the wife of Surgeon A. G. McKee, R.N., of a son.

PATTISON.—On August 10th, at Hollow Meadows, Sheffield, Pamela, the wife of C. Lee Pattison, M.B., B.S. Lond., of a son.

RICHARDS.—On August 9th, the wife of Lieutenant J. E. Richards, R.A.M.C., of a daughter.

MARRIAGES.

ADDINSELL—KERRISON.—On August 8th, at St. George's, Hanover-square, Augustus W. Addinsell, M.B., M.R.C.P., to Mrs. Diana Kerrison, of Tattingstone.

DEATHS.

DERRY.—On August 8th, at St. Leonard's House, Bodmin, Bartholomew Gidley Derry, M.R.C.S. Eng., L.R.C.P. Lond., aged 71 years.

LLOYD.—On August 4th, killed in action, Captain W. H. Lloyd, M.B., B.S. Lond., M.R.C.S., L.R.C.P., aged 27.

NIALL.—On August 7th, at Dulwich-road, S.E., Eugene Hayes Niall, L.R.C.P. & S. Edin., aged 76 years.

WALTERS.—While on a visit to Ashbrook Hall, Hollington, Sussex, John Basil Walters, M.R.C.S., L.R.C.P.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

EDITORIAL NOTICE.

In consequence of the pressure on our space and the shortage of paper, the Editor may be compelled to abbreviate communications, as an alternative to their rejection, when time does not allow them to be reconsidered by their authors.

Communications, Letters, &c., to the Editor have been received from—

A.—Major A. Abrahams, R.A.M.C.; *Answers*, Lond., Editor of; Mr. R. J. Albery, Lond.; Miss L. G. Ackroyd, Bramhall.

B.—Miss C. S. Bremner, Crosthwaite; Board of Education, Lond., Sec. of; Capt. W. Langdon Brown, R.A.M.C.(T.); British Science Guild, Lond.; Messrs. Butterworth and Co., Calcutta; Pte. A. G. Bedane; Mr. J. Brindley-James, Lond.; Mr. S. Bhatta; Dr. H. W. Bywaters, Bristol; Major W. Brown, R.A.M.C.

C.—Capt. J. Campbell, R.A.M.C.; Mrs. E. S. Chesser, M.B., Lond; Mr. J. Cabburn, Lond.; Dr. E. L. Collis, Lond.; Dr. W. M. Crofton, Dublin.

D.—Dr. W. R. Dunstan, Lewes; Capt. A. D. Dunne, R.A.M.C.(T.), Capt. S. C. Dyke, R.A.M.C.; Lieut.-Col. A. M. Davies, R.A.M.C.

E.—Major R. Eager, R.A.M.C.(T.), Ex-Officers Employment Bureau, Lond.

F.—Mrs. S. E. Foott, Cork; Capt. C. D. Farquharson, C.A.M.C.

G.—Mr. M. Gault, Limavady; Dr. H. L. Gordon, Lond.; Mr. F. C. Goodall, Lond.

H.—Mr. A. Harden, Lond.; Dr. J. H. Hart, East Molesey; Capt. E. Hindle, R.E.

J.—Dr. G. Jessel, Wigan.

K.—Major M. F. Kelly, R.A.M.C.; Mr. W. H. Kesteven, Kingston Hill; Dr. D. Keilin, Cambridge.

L.—London (Royal Free Hospital) School of Medicine for Women, Warden of; Dr. R. B. Low, Lond.; Dr. T. Lumsden, Lond.; Mr. E. P. Leavy, Innisfail; Messrs. Lea and Febiger, Philadelphia.

M.—Dr. D. L. Mackinnon, Aberdeen; Malay States Information Agency, Lond.; Mr. W. B. McCall, Birmingham; Mr. J. E. R. McDonagh, Lond.; Metropolitan Asylums Board, Lond.; Ministry of Munitions, Director of Special Intelligence, Lond.; Capt. J. C. McWalter, R.A.M.C.

N.—National Physical Laboratory, Teddington.

O.—Dr. H. C. Orrin, Lond.

P.—Dr. H. W. Pooler, Alfreton; Dr. E. E. Prest, New Cumnock.

R.—Dr. H. S. Reynolds, Wisbech; Mr. P. B. Roth, Lond.; Dr. H. Rahmet Bey, Cairo.

S.—Capt. R. Steele, R.A.M.C.; Summer School of Civics and Eugenics, Lond., Sec. of; Dr. H. Sutherland; Dr. G. E. Shuttleworth, Bournemouth; Mr. W. Scott, Bridgwater.

T.—Dr. J. Tatham, Oxted; Capt. W. J. Tulloch, R.A.M.C.; Mr. H. B. Tawse, Nottingham; Capt. A. G. Tressider, I.M.S.

W.—Mrs. M. B. Wilson, Petworth; West Sussex County Asylum, Chichester; Dr. P. L. Watkin, Williams.

Notes, Short Comments, and Answers to Correspondents.

COLONIAL HEALTH REPORTS.

Nyasaland.—A report prepared by Mr. G. B. Anderson, acting Assistant Chief Secretary, dealing with the year ending March 31st, 1917, states that during that period the public health was not as satisfactory as heretofore owing to military requirements for labour having necessitated an abnormally increased movement of natives in all parts of the territory.

"Small-pox," Mr. Anderson records, "was still confined to the Lilongue and Dowa districts, and although labour was recruited from both these areas the precautionary measures which were instituted proved successful in preventing any spread of the disease. Two localised outbreaks which occurred in the Zamba and Upper Shire districts respectively among labourers employed on the military roads were promptly and effectually dealt with. As in the previous year, sleeping sickness investigations were confined to the proclaimed area in the Dowa district, the number of cases reported amounting to 31. In 1915 the figures were 25 from this area, plus 4 from other parts of the Protectorate, making a total of 29. It would be misleading to assume that these figures represent the actual incidence of sleeping sickness in the Protectorate as a whole, for the results of investigations in the past have shown that the portion of the Yarimba district bordering on the lake is as heavily infected as the proclaimed area in the Dowa district. It is much to be regretted that bubonic plague has made its appearance in the Protectorate for the first time. Every effort was made to ascertain the source whence this disease gained entry into the North Nyasa District, and inquiry has shown that there can be little doubt but that it was introduced from German East Africa during the latter part of the year, when there was considerable movement of the native carriers between Karonga and Yuraya. Three cases of bubonic plague were reported in the neighbourhood of Karonga in the month of November, 1916, and ten in December. Further cases occurred during the following months, but at the moment of writing it is satisfactory to record that following the campaign of rat extermination, inoculation, and the adoption of other preventive measures, the outbreak is now well in hand and the disease has not shown any indication of spreading to other parts of the Protectorate. The number of Europeans resident in the Protectorate, including officials and non-officials, was 474 males and 257 females, or a total of 731, as compared with 523 males and 262 females, or a total of 785, in the previous year. The Asiatic population amounted to 391, as against 379 in the preceding year. The native population is estimated at 1,137,266, being approximately 506,785 males and 630,481 females."

British Honduras.—A report furnished to the Colonial Office by Mr. W. L. McKinstry, Acting Colonial Secretary of British Honduras, states that the estimated mean population for the year 1916 was 42,323, consisting of 21,101 males and 21,222 females. The following table shows the number of deaths for every 100 births registered during the years 1911–15 inclusive, according to their race classification, and as compared with 1916:—

Race.	Deaths for every 100 births, 1911–15.	Deaths for every 100 births, 1916.
Indian	80·76	100·5
Carib	52·05	43·79
Negro	53·89	59·51
Other races	63·51	57·99

The birth-rate was 39·056 and the mortality 26·321 per 1000 of the estimated mean population. The number of illegitimate births was 687 out of a total of 1653, or 41·56 per cent. 413 marriages took place during the year, being at the rate of 9·75 per 1000 of the mean population. During 1916 the excess of female over male births was 85; and of male over female deaths 150. The colony suffered sudden and severe losses in the untimely deaths of Lieutenant-Colonel Slack and P. C. Burgess, at the hands of a murderer, and Dr. J. H. H. Harrison, the principal medical officer, at the hands of a lunatic. The deepest sympathy of all classes was extended to the bereaved families. The health of the colony had been on the whole good. Slight epidemics of dengue, measles, influenza, and chicken-pox occurred, but were all of a mild type. Infantile mortality was unfortunately very high in most districts. During the first six months of the year 1916 Dr. Hackett, of the Rockefeller Institute, conducted an inquiry into the prevalence of ankylostomiasis throughout the colony. He found an infection varying from practically nil on the Cayes to nearly 100 per cent. in some of the Indian villages. Determined steps were taken to combat the disease.

Northern Territories of the Gold Coast.—In his latest report on this Protectorate Mr. C. H. Armitage, the Chief Commissioner, states that two deaths occurred among the European officials—one from heart failure in February at Tamale and one from yellow fever at Gambaga in October. The names of 12 officials appeared on the sick list. Among the native officials only 16 entries occurred on the sick report, with one death. The Census, completed in 1911, gave an estimated native population of 361,806 to the Northern Territories, with a computed area of 31,100 square miles, an average of 11·6 persons to the square mile. The Census returns for the Southern and North-Western Provinces were considered to be fairly accurate, but those of the North-Eastern Province fell far short of being correct, and it is estimated that not more than two-thirds of the inhabitants were enumerated. In spite of the heavy infant mortality it is considered that the population at the present day is greatly in excess of that shown in the last Census returns. Except for an outbreak of small-pox at Wa at the end of the year, no epidemic disease was recorded. It is reported that the Walas inoculated their children from the virus obtained from those who contracted small-pox. Two deaths from anthrax occurred at Salaga. Leprosy is not on the increase, and, while uncommon in the Southern and North-Western Provinces, is of more frequent occurrence in the North-Eastern Province. The natives look upon it as "a visitation of Allah," but say that it shows no signs of spreading, and are generally averse to compulsory isolation. In concluding his report, Mr. Armitage remarks that:—

"The climate of the Northern Territories, while similar to that of the Gold Coast and Ashanti, may be said in comparison with them to be more trying in its extremes. It possesses an insidious quality that lowers the vitality of Europeans and renders unduly prolonged residence on their part inadvisable, and it is generally recognised that a period of recuperation in a more bracing and salubrious climate is necessary after a year's stay in the country. Innumerable insects—creeping and flying—are a source of irritation, especially at evening time and after dark."

BORO-CHLORETONE IN THE TREATMENT OF BURNS.

To the Editor of THE LANCET.

SIR,—I should like to draw the attention of those of your readers who have not yet tried it to the value of this powder in the treatment of burns and scalds. I have used it for several years and have found it most efficacious, and its marked success in a recent case of a young girl, whose leg and foot were badly scalded, was most noticeable. I found her screaming with pain. Within five minutes of a copious dusting of the damaged skin with boro-chloretone all pain had disappeared and she was able to sleep the whole night. The next day the circumvesicular erythema had distinctly faded, and healing rapidly ensued. Boro-chloretone not only anæsthetises the skin but diminishes the inflammation, and being in addition an antiseptic fulfils the qualifications of an ideal dressing for burns and scalds.

I am, Sir, yours faithfully,

Watton, Norfolk, August 4th, 1918. H. MALLINS.

MEMORIAL TO THE LATE MR. R. H. GRIMBLY, O.B.E., M.R.C.S., L.S.A.

ON July 11th, at Newton Abbot Ambulance Hall, a memorial tablet was unveiled to the memory of the late Mr. Richard Henry Grimbly, who was the founder of the local corps of the St. John Ambulance Brigade.

EGG "SUBSTITUTES."

AN editorial article in the *Journal of the A.M.A.* for July 13th has some hard things to say about the numerous products at present vaunted in America as efficient substitutes for the hen's egg. At the request of the Pennsylvania State Department of Agriculture, Professor C. H. Lawall has investigated more than 40 of these substitutes, and in the introduction to his report he says:—

One of the most reprehensible ways of making money is to take some common, everyday substance, disguise or alter its appearance in some way, make a lot of exaggerated statements regarding it, and then sell it for about 10 or 15 times its market value, extolling it as an economical substitute for some expensive article. There has been no preparation of this class within recent years that has sprung into prominence with such rapidity as the so-called egg substitutes and with so little merit or legitimate warrant for their manufacture and sale.

Practically all the substitutes have been found to consist chiefly of cornstarch coloured with coal-tar dye. The protein content varied from 0·7 to 35 per cent. Commercially dried egg, which is a legitimate market product, contains about 45 per cent. of protein. Professor Lawall concludes that all so-called egg substitutes afford a ready opportunity for profiteering, combined with the development of the art of camouflage to the point of perfection.

"Their names are deceptive; their composition in no wise resembles that of egg; the presence of colour, in those where it is used, is a fraud, and the claims as to replacing value are either deliberate misstatements or ambiguous phrases. Egg substitutes serve no purpose that cannot be served just as satisfactorily and much more cheaply by articles in daily use in every household."

The egg "substitutes" are probably similar to what are known in Great Britain as custard powders, which are presumed to make "custard without eggs." In this country there is no legal definition laying down a standard, so far as we know, for such powders, although in Pennsylvania such substitutes contravene the State food regulations, and if found for sale are dealt with accordingly. As was shown in a report from THE LANCET Laboratory in 1900 (THE LANCET, May 5th, 1900, p. 1298) the powders consist practically entirely of cornstarch coloured with turmeric or coal-tar dye. They have therefore nothing in common with eggs, and the "custard" made from them is merely a starch emulsion with very small real nutrient value.

SOME MEDICAL NOTES FROM ANCIENT MESOPOTAMIA.

Dr. Paul Haupt, of Johns Hopkins University, has, in the *United States Oriental Research Journal*, been giving a revised translation of the difficult cuneiform text in the Annals of Assurbannipal, king of Assyria, describing the illness of Teumman, king of Elam, with whom the Mesopotamians were at war. This record has been for the last 40 years differently rendered, and was thought to indicate that the disease was rabies, because one sentence is capable of being read as "he behaved like a mad dog"; but Professor Haupt, after an elaborate discussion of the text from our knowledge, now so advanced, of the cuneiform vocabulary, and a comparison of the words with their congeners in other Semitic dialects, shows that the following is the correct translation. "At that time he (Teumman) had an attack, his lip slavered, his eye rolled; wildness was imported to it." This version agrees quite closely with the malady being an epileptic fit, for during an attack of morbus sacer the eyes roll wildly and the sufferer foams at the mouth. The ancients were agreed that such disease was specially inflicted by the gods, and in a further part of the inscription the origin of it is attributed to Assur and Ishtar.

The existence of veterinary surgeons in very early times in Babylonia is disclosed by the ancient law code of King Hammurabi. This is confirmed by a cuneiform tablet, Rm. 362 in the British Museum, which, though much defaced, scholars can detect gave a list of plants useful for treating colic in the horse. One line reads, "Plant for abdominal cutting pain in the horse." Other lines read in Babylonian what is most nearly translated by "Contunde in vino, ungue ad abdomen." This tablet probably presents the earliest known instance of cataplasmata being utilised for treatment of colic of the horse.

Dr. Felix von Oefele, whose residence appears now to be in New York, has been writing in the *Journal of the American Oriental Society* upon a Babylonian statuette of the jerboa, or Egyptian jumping mouse, especially with regard to the accurate representation of zoological details showing careful morphological observation. The double length of the tibia in comparison with the femur is carefully copied. The animal is still to be found in the Western Babylon desert, and doubtless it was there, and not in the Sinai peninsula, that the artist obtained the specimen he copied.

"VITAMOGEN."

To the Editor of THE LANCET.

SIR,—My attention has been called to a leaflet composed of extracts from an article of mine on Vitamines published in *Science Progress*, 1914, followed by references to a food preparation called "Vitamogen" purporting to contain these accessory growth substances.

The publication of my name in connexion with this matter is entirely without my sanction, and should not be taken to imply that I consider that there are any vitamines in the above-mentioned preparation.

I am, Sir, yours faithfully,

Bristol, August 12th, 1918. H. W. BYWATERS, D.Sc.

*** We have also received a communication from Vitamogen, Ltd., in which they enclose a copy of a letter which this company wrote to Dr. Bywaters on his drawing their attention to the matter. The letter is as follows:—

[COPY.]

Professor H. W. Bywaters, July 31st, 1918.
c/o Messrs. Fry and Sons, Ltd., Bristol.

DEAR SIR,—We have yours of the 24th inst. addressed to Mr. Shepperson, and we are very sorry you feel you have cause for grievance against us.

We assure you that we had no intention of doing anything to cause you to feel any disturbance of mind, as we have acted quite innocently in the matter, inasmuch as, after Mr. Shepperson's interview with you at Bristol, on your suggestion he communicated with Mr. Murray regarding the loan of the blocks, and at the same time mentioned that we should like to publish extracts from your paper and his reply was, that "provided the usual acknowledgment is made of the source from whence it is taken." This is from his letter which we have before us at the moment, dated Oct. 29th, 1917, and you will observe we have done this, and a proof of our leaflet was sent to the publishers of *Science Progress* for perusal before we issued it.

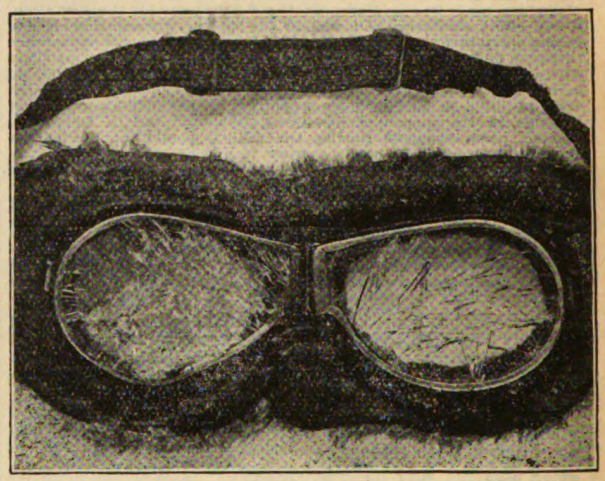
We remain, yours faithfully,
VITAMOGEN, LTD.

HOUSEHOLD ECONOMY.

THREE recently published little books will greatly help towards household economy in regard to the preparation and preservation of food. The first, *The Commonwealth Cookery Book*, by Muriel V. Palmer (London: Longmans, Green, and Co. Price 2*s.* 6*d.*), contains within the compass of 124 pages a large number of recipes, the result of many years of experience, the author being organiser of domestic subjects to the Birmingham Education Committee. This thoroughly practical little book gives instructions for the preparation of every-day dishes, including the requirements of invalids, and for the simple preservation of fruits and vegetables. A recipe supplied by Messrs. Cadbury Bros. for a cocoa-butter emulsion makes for economy in cake and biscuit making.——*Canning and Bottling*, with notes on other simple methods of preserving fruits and vegetables, by Helen P. Goodrich, D.Sc., late technical adviser on canning in the Food Production Department (Same publishers. Pp. 70. Price 2*s.*), deals with the subject in a very simple and thorough manner, the first part presenting all the information necessary for the successful preservation of fruits and vegetables, the last part being devoted to more technical and theoretical matters interesting to those proposing to can on a large scale. The author believes "that the saving of fruit and vegetables may not only be effected during the war, but, through the lessons in economy that we are learning now, a pleasant and financially sound occupation may be fostered as a permanent national village industry, which cannot but make agricultural life more attractive."——An enlarged edition of Miss Helen Wyldon's *Sugarless Jam Making*, published at 10, Glendale-terrace, Bideford, Devon, price 1*s.* 2*d.*, post free, also contains instructions on preserving fruit and vegetables as well as bottling and drying, corn syrup preserving, together with hints for canners. At a time when there is a shortage of sugar this little book, with a score of recipes, should prove useful.

TRIPLEX GLASS.

Mr. Charles Higgens recently called attention in this column to the properties of this glass and the protection which it offers to the eyes of our fighting men. We have received from the Triplex Safety Glass Co., Ltd.



(1, Albemarle-street, W. 1), a photograph, which we reproduce here, of a pair of safety-glass goggles which stood a severe test. A lieutenant in the R.A.F. writes that he was wearing the goggles when he crashed, and that they were the means of saving his eyesight.

MATERNITY FEES IN EAST RIDING.

THE county medical officer has reported to the Health Committee of the East Riding county council that he has been in communication with the acting secretary of the East Riding local medical committee with regard to the fees to be paid by the county council under the maternity and child welfare scheme to practitioners who were summoned in necessitous cases by a midwife employed by the council, and also to practitioners who attended, under arrangements made by the council, necessitous women at confinement. The fees suggested by the local medical committee were as follows:—

1. Where the practitioner is called in by the midwife in a necessitous case, and the distance is within three miles, not exceeding £2 2*s.*; where the distance is more than three miles, not exceeding £3 3*s.* The fee for subsequent visits to be 3*s.* 6*d.*, plus mileage of 1*s.* a mile or part of a mile one way.

2. Where the practitioner undertakes the case by arrangement with the council:—

	£	*s.*	*d.*
Where the distance is a mile or under	1	11	6
" " over one mile and under three miles	2	2	0
" " three miles and over	2	12	6

The committee approved of this scale.

SOMERSET CENTENARIANS.

Mrs. Russell, of Weston-super-Mare, celebrated the 100th anniversary of her birthday on July 19th. Weston-super-Mare has had four centenarians within the past four years.—Mr. F. W. Stabbius, of Worle, was 103 years of age on July 18th.

J. S. McW. has omitted to give the reference for the statement which he quotes.

The Lumleian Lectures
ON
CŒLIAC DISEASE.

BY G. F. STILL, M.A., M.D. CANTAB., F.R.C.P. LOND.,
PROFESSOR OF DISEASES OF CHILDREN, KING'S COLLEGE, LONDON; PHYSICIAN FOR DISEASES OF CHILDREN, KING'S COLLEGE HOSPITAL; PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

LECTURE III.*

MR. PRESIDENT AND FELLOWS,—In this, my third lecture, I propose to consider the treatment of cœliac disease.

This section of my subject I approach with considerable diffidence, for in face of the modern therapeutics which the brilliant investigations of laboratory workers in chemistry and bacteriology have made applicable to many diseases, one feels almost out-of-date in offering suggestions and observations based chiefly on clinical experience.

As, however, I have shown in the previous lecture, it has not been possible to trace cœliac disease to one specific cause. Until this has been done, or until the clinical grouping which has been called by this name is shown to be divisible into several different specific entities, the treatment must necessarily be more or less symptomatic and empirical. In the meantime experience has shown that certain lines of treatment are definitely valuable in many cases included under this heading, and these I shall try to indicate; moreover, as negative observations are sometimes hardly less important than positive, I shall refer also to the failure of various methods which on theoretical grounds have been thought worthy of trial.

DIETETIC TREATMENT.

One of the outstanding features of cœliac disease is failure of fat assimilation.

This failure has not only a negative result in depriving the child of important material for nutrition, but also a positive result in leaving in the food-residue in the bowel an excess of fatty substances which favours putrefactive change, and in this way may lead to local irritation and secondary infections, and more remotely may cause symptoms of toxic absorption. Possibly also the excess of fat remaining unabsorbed may interfere with the digestion of other food by covering it with an oily coating which digestive secretions have difficulty in penetrating. Failure of assimilation of any element of food is liable, in various ways, to have a more profound effect upon nutrition than the mere loss of that particular element would entail, for by its secondary effects in the bowel it may, and evidently does, interfere with the absorption of other food elements.

Reduction of Fresh Cow's Milk.

I suppose this to be the reason of the value of a diet from which fresh cow's milk is altogether excluded. I place this point foremost in the treatment of "cœliac disease," for I know of no other item of equal importance. Experience shows also that it requires emphasis, for the tendency is to put such a case upon milk and more milk, as the one thing needful, whereas nothing is more likely to retard recovery.

Dr. Gee's experience led him to the same conclusion. "Cow's milk," he says, "is the least suited kind of food for them"; but he attributes this intolerance of milk to the curd, not to the fat. "Nothing is more certain," he adds, "than that cœliac children cannot digest the hard curd of ruminants' milk."

I think the balance of evidence is against this explanation of the harmfulness of cow's milk in this disorder. As he himself points out, peptonising milk does not make it any more suitable for these cases, as it should do if the difficulty were chiefly or entirely curd indigestion. I would add that the use of dried milk, the curd from which is much less tough and consequently much more easily digested than that of cow's milk, produces little or no improvement in the stool unless the proportion of fat in the dried milk is much less than that in the fresh milk. The stools show no evidence of curd indigestion, whereas they do show very marked deficiency of fat absorption. Cream, even much diluted, is not tolerated, as it should be if the milk difficulty was due only to the curd.

My own observations, in agreement with those of other clinicians, show that the best results are to be obtained in the dieting of these children by reducing the fats to a minimum, and as the food in which fat is chiefly given at the age when these children come under treatment is cow's milk these observations have applied chiefly to this particular form of fat.

Dried Milk with Reduced Fat.

I have found most successful the replacement of fresh milk altogether by a dried milk containing only a small proportion of milk fat.

The particular brand—"Cow and Gate Half Cream"—which I have used is stated to contain half the proportion of fat present in milk.

Analyses showed that dried milk requires using with special precautions, otherwise the proportion of fat in the food may be very different from that intended. The very light, almost flaky, powder is very easily compressed, so that if on opening a full tin of this half-cream dried milk a fully-heaped, large-sized teaspoonful is taken and added to 1 oz. of water the resulting proportion of fat is no less than 3·1 per cent. (the amount of the powder taken thus was found to be about 75 gr.), whereas if the powder be turned out of the tin or shaken up, as it would be in a partially emptied tin, the same teaspoon heaped fully with the loose powder contains barely 50 gr. and gives with 1 oz. of water only 1·8 per cent. of fat.

Why the small amount of cow's milk fat contained in the dried milk should be better tolerated than the same proportion of fat in fresh cow's milk is not apparent.

Indeed, one would rather have expected the reverse, for the emulsion of the fat in a solution of dried milk is so imperfect that it tends to form into visible droplets on the surface and forms a greasy coating on the vessel in which it is given. Sometimes, indeed, I have wondered whether the loss of a certain amount of fat to the child in this way may not have facilitated the digestion of these preparations.

Human and Other Milk.

It might very reasonably be argued that if the fat is the difficulty then any milk which contains as high a proportion of fat as cow's milk should be equally unsuitable.

This, however, is not so. The difficulty of assimilating the fat of fresh cow's milk seems to be a specialised intolerance, for the fat of human milk, though present in larger proportion than is often found in cow's milk, is seemingly tolerated excellently by these children.

Usually their age makes it difficult to utilise this form of feeding, but in two cases where life seemed to be seriously threatened by cœliac disease, I was able to obtain human milk, which was used in one of them from the age of 2¼ years for nearly a year, and in the other from the age of 20½ months until the child was 2 years and 11 months old.

In both cases the human milk seemed to be the turning point in the illness, and its use was followed by great improvement in the stools and in the child's general condition, so that one case made a complete recovery, though with some stunting of growth, and the other, last seen at 3 years and 10 months, showed no arrest whatever of growth and was able by this time to take both cow's milk and goat's milk.

In connexion with this special value of human milk I would recall a fact which I have already mentioned, that none of my cases of cœliac disease began in an infant who was still at the breast.

One of the most successful substitutes for cow's milk is asses' milk.

This might be expected from the very low proportion of fat which it contains, commonly not more than 1 per cent. Whether this is the whole explanation may, however, be doubted, for cow's milk, even when diluted so as to reduce the proportion of fat to this extent, or when used in the form of whey, which contains usually not more than 1 per cent. of fat, is still much more liable to render the stools loose and offensive.

Apart from the proportion of fat present it is recognised that there are differences in the characters of the fat in the milk of different animals, notably in their melting point, also in the proportion of butyric acid present as well as in other respects, and it may be that these differences determine the digestibility of different kinds of milk fat, and therefore their relative suitability in such a condition as cœliac disease.

Fat Derived from Other Sources.

Fats other than those present in milks have also proved unsuitable.

I have tried the oil obtained from soya bean in the form of an artificial milk, Solac, containing 3·3 per cent. of fat according to one analysis, and 3·75 per cent. according to another, but in spite of good emulsion this was not successful; it aggravated the looseness of the bowels.

Cod-liver oil also is not available to replace the milk fats, for it is usually tolerated badly in this disorder.

Another form of fat which, though tolerated by some of these children in small quantities, increases the symptoms in others, is that present in the yolk of egg.

The evidence of intolerance of these various fats is the increased looseness of the stools and still more their offensive character. The reduction of the proportion of fat in the diet produces not only diminution of looseness but a better colour and less offensive odour of the stools, and therewith a definite improvement in the child's general condition, and particularly in the weight.

Carbohydrates.

The diet, however, must needs consist of something more than a milk very poor in fat if any continuous improvement of nutrition is to be obtained.

There is apparently some difficulty in dealing with starches, though much less than with fats.

Unfortunately, one form of starch which seems particularly liable to aggravate the symptoms is bread. I know of no adequate substitute. Rusks have seemed less harmful than bread, probably owing to the fact that the starch in them is partially dextrinised; they help to satisfy the child's craving for something solid. For this reason, though they contain very little carbohydrate, I have used biscuits made with dried

* Lectures I. and II. were published in THE LANCET of August 10th (p. 165) and 17th (p. 193), 1918.

milk, with just enough wheaten flour to give a crisp consistency; there have been at least two such in the market, "Nurso" and "Malac" biscuits. Sugar is allowable only in small quantity.

A form of carbohydrate which generally suits these cases is "Revalenta," prepared from lentils; this made thin with a solution of the dried milk and sweetened with sugar, though not very palatable, is generally taken well. Rice boiled in water for three or four hours so that it is almost a jelly is another form of carbohydrate which has usually succeeded.

These foods, with the addition of chicken broth or veal broth and sweet jellies, have made up the total dietary, in some cases, for a year or more, and if anyone tries to draw up a menu from this list he will find that it is meagre indeed. If eggs are tolerated it eases the difficulty considerably. Pounded chicken, or fish, or meat, or brains, generally make the looseness of the bowel worse, and are only suitable when the child is already improving.

Apart from the fact that such a diet is unsatisfying to the child, it is definitely scorbutic.

Five of my cases developed scurvy at ages varying from 4½ years to 10½ years. All of these were on dried milk and the diet I have mentioned, a proof incidentally that these dried milks, if they contain vitamines at all, do not contain sufficient to prevent scurvy. Obviously, it is important to give some antiscorbutic, and sometimes there is no difficulty, for grape-juice can be given to some without increasing the looseness of the bowels, but usually fruit juices and green vegetables have to be avoided on this account.

Other Diets.

Various have been the efforts to find a diet upon which these children will do well.

One of the most remarkable is that mentioned by Dr. Gee: "A child who was fed upon a quart of the best Dutch mussels daily throve wonderfully well, but relapsed when the season for mussels was over; next season he could not be prevailed upon to take them. This is an experiment," he says, "which I have not yet been able to repeat."

There may have been more reason in this method of feeding than at first appears, for, like most of the diets which have succeeded, it is one containing a low proportion of fat. Moreover, while containing a high proportion of proteid, it contains, of course, no carbohydrate. The mussel contains 12·5 per cent. of proteid and only 1·6 per cent. of fat.

I have tried in some cases a so-called "fat-free" diet with marked success.

From this even the dried milk and egg are excluded, and the diet consists of rusks, Robb's biscuits, jellies, chicken and veal broth, rice boiled in water, revalenta, mashed potato, pounded chicken or fish, barley water or weak tea with sugar. On this diet there has usually been great improvement and in six cases slow but steady recovery.

In this diet the potato fulfils a double purpose by not only providing a considerable number of calories, but also a most effective antiscorbutic. It has seemed to me to be better tolerated in this fat-free diet than when given in a diet including milk, dried or otherwise. This impression is confirmed by one's experience in some of the commoner digestive disturbances of childhood, where one has often noticed that the combination of oily substances—for instance, butter—with potato seems to render the potato particularly indigestible, possibly for the reason already suggested, that the fatty material forms an envelope around the starch granules preventing the diastasic action of the amylase of the salivary and pancreatic secretions.

Diet with Little or No Fat: Freedom from Rickets.

It might be thought that a diet practically devoid of fat, or even such a régime as that previously mentioned in which the fat is reduced to an extremely small amount without being excluded altogether, would, when continued for months, or, as has been necessary in some cases, for two or three years, produce serious harm; especially when it is used, as it is almost always in this disease, at an age which should be that of rapid development. I have already pointed out that in spite of the deficient fat assimilation caused by the disease rickets is strikingly absent in the large majority of children with cœliac disease; and now I will add that even when fat is eliminated entirely or almost entirely from the diet these children still show a remarkable freedom from rickets.

Other Routes of Introducing Fat: Inunction.

Admitting, however, that in this direction the low proportion of fat in the diet does no harm, it must still be desirable from the point of view of general nutrition to secure the absorption of fat if possible, and the question arises whether for purposes of tissue building fat can be introduced by any other route than the alimentary canal.

There is some evidence not only that it can be absorbed but that it can be used for tissue building when injected into the subcutaneous tissues. Such a mode of administration is obviously undesirable for children, especially as it would have to be repeated many times and for a long period.

Can fat be introduced by inunction?

If so, it would be simple enough to compensate for the deficiency of fat digestion. There is plenty of evidence that various substances applied in oils or ointments are absorbed—e.g., mercury in mercurial ointment or iodoform in oil or in vaseline; but this is no proof that the fat of the oily vehicle is absorbed also.

I have sought in vain for confirmation of statements that cod-liver oil and other fats can be introduced through the skin. The only experimental evidence which I have been able to find was that obtained by Lassar, who smeared the shaven skin of rabbits with rape-seed oil three times a day for two or three days, and found that the liver and kidneys after this short time were full of fat globules. He stated also that olive oil and cod-liver oil passed through the skin into the deep organs.

As far as I know, these experiments have not been confirmed, and it has been pointed out (Reid [13]) that the skin of mammals usually employed for such experiments is thinner than that of man and more vascular, and in the case of the rabbit in particular contains hair follicles with wide mouth, so that the conditions are not strictly comparable.

If fat can be absorbed through the skin it must presumably be without the fat-splitting and subsequent synthesising which are supposed to be necessary to its absorption through the bowel. It is difficult to believe that if with such special adaptation to absorption as is shown in the structure of the intestinal mucosa such an elaborate process is necessary to the absorption of fat it can be absorbed without any preparation at all through such a structure as the skin.

It is much to be desired that careful clinical observations under strict conditions could be made on this particular point.

Most of us have ordered inunctions of oil many times for wasting children, who sometimes have thereupon gained weight and sometimes not, but there are so many possible fallacies, and so few cases offer the exact conditions favourable to any decisive conclusion, that such inunctions are usually rather the therapeutics of hopefulness than the therapeutics of conviction. Personally, I have been under the impression that any good accruing was due rather to the friction and perhaps the warm covering of oil than to any real absorption.

It is important for investigation that the cause of the wasting should be mainly, if not entirely, failure of fat absorption by the bowel. The presence of some other cause of wasting, such as tuberculosis or any general failure of digestion, will make the results of inunction even more doubtful, as any gain from skin absorption may be counterbalanced by loss of nutrition from other causes. In "cœliac disease" we have a condition in which presumably the predominating factor in the failure of nutrition is failure of fat absorption from the bowel, and therefore a state of things particularly suited to this investigation.

Results in Cases Treated by Inunction.

With this point in mind, I tried the effect of inunction with peanut oil (oleum arachis), two drachms being rubbed in twice daily for about 15 minutes.

The patient was a boy aged 7½ years who had been under my care in hospital for five weeks with cœliac disease without gaining weight. On admission he weighed 28 lb.: at the end of five weeks only 25½ lb. At this stage the daily inunction was begun, and the boy's weight steadily rose so that in the next eight weeks he gained 8½ lb., and this in spite of the stool being often very pale and slimy and purpura appearing most of the time.

This observation is certainly suggestive of the possibility of fat absorption through the skin, but I am bound to admit that even with such a favourable opportunity for investigation as cœliac disease my results in other cases have been equivocal.

In one case the inunction, done with cotton-seed oil, and subsequently with peanut oil, produced no definite gain in weight, whereas in another case of cœliac disease in the same ward, where the weight had been stationary for many weeks, the weight began to rise almost steadily, and the child's condition improved enormously without any change in the treatment, and in particular without any inunction.

An unexplained improvement like this has happened in several cases where the disease had already lasted two or three years without any permanent progress. It behoves us, therefore, to be careful in attributing results to our treatment, whether it be fat inunction or any other.

TREATMENT BY DRUGS, ORGANIC EXTRACTS, AND VACCINES.

Another method of overcoming the fat difficulty which has been tried in these cases is the administration of digestive extracts.

In view of the striking results obtained by Dr. Byrom Bramwell in cases of pancreatic infantilism, a condition associated, like that we are considering, with failure of fat assimilation, it seemed possible that pancreatic extracts would be of value in cœliac disease.

I have repeatedly used them, trying in various cases the glycerine extract specially recommended by Dr. Bramwell, also the preparation sold under the name of "holadin," and that sold as "trypsogen," but none of them have appeared to me to have any obvious beneficial effect, a confirmation, incidentally, of the conclusions reached in my previous lecture that the failure of fat assimilation is not due to the failure of the pancreatic secretion.

I have also tried ox-gall on the theory that the biliary secretion was deficient, but without any improvement in the stools or in the child's condition.

Calomel.—Digestive Extracts.

Dr. Cheadle recommended calomel as stimulating hepatic secretion, as well as having some antiseptic value.

So far as my own experience goes, the facts certainly do not fit the theory, for calomel, and even grey powder, seem to aggravate the bowel disturbance and to be particularly unsuitable for these cases.

Dr. Cammidge quotes one observer as having found that calomel, so far from diminishing the number of bacteria in the fæces, may actually cause an increase, presumably by increasing the mucus which serves as a favourable nidus for bacteria. Whatever may be the explanation it certainly does not improve either the stools or the patient in cœliac disease.

The difficulty in digestion of carbohydrates, particularly of starch, which is only less than the fat difficulty, naturally suggests the administration of malt for its diastasic effect. This, however, is also found to be inadmissible in most cases, for it seems rather to promote flatulence and looseness.

It would seem, indeed, so far as any direct influence can be exerted upon the absorption of fats and carbohydrates in cœliac disease, it is rather to be accomplished by rigorous dieting than by any drugs or digestive extracts.

Astringents.

Drugs, however, even if they are of but little assistance in this affection to the digestive processes which prepare the food for absorption, may still be of real value if they can render the intestinal mucosa more healthy, and therefore more capable of absorbing.

Post-mortem examination has shown that, at any rate in a fatal case, there may be definite inflammatory change in the intestine, and the

presence of much mucus in the stools during life, especially when the disease has already been present for a long time, shows that there is at least much intestinal catarrh, and these changes are apparently due, in part at least, to bacterial irritation and partly to the irritating effect of putrefaction.

It might be supposed that this could be diminished in two ways, either by drugs which exert an astringent effect upon the mucosa, or by those which have some antiseptic value and in this way prevent bacterial growth and putrefactive changes.

Most of the astringents, whether vegetable or mineral, have proved useless in my hands; the only one which has an undoubtedly good effect is castor oil.

Given in small doses, three times daily, it usually causes more or less improvement.

A mixture of 5-minim doses of castor oil with salol 2 or 3 gr. in mucilage and water has such a pronounced effect in improving the stools and checking looseness that in several cases the child took it almost continuously for some years, and the parents stated that any attempt to discontinue it was usually followed before long by deterioration in the character of the stools, so that the medicine had to be resumed.

It has always seemed to me difficult to understand how five drops of castor-oil can have any astringent effect on 20 feet of intestine, but however it is to be explained there is no doubt that it has a very definite action in this respect.

Another astringent which, though much less reliable than castor oil, is certainly sometimes useful in cœliac disease is silver nitrate, which in doses of ¼ or ½ gr. ter die seems to reduce the looseness of the stools in some cases.

Bismuth has seemed to me to be usually of little, if any, value in these cases, perhaps because it was used in the traditional doses of 10 gr. or even 5 gr. three or four times a day, whereas the radiographers have taught us that bismuth can be taken by the ounce without ill effect, so that recently infants in my ward sometimes have 30 gr. of bismuth carbonate every three hours, and a child of three as much as 60 or 70 gr. several times a day.

Chromo-santonin.

Having in mind the resemblance in many points between cœliac disease and sprue, I have tried in three cases the chromo-santonin, which Dr. Charles Begg has found to have remarkably beneficial effects in sprue.

It was given, as he directs, in a gelatine capsule. There were no records from which the dosage proper to children of this age and suffering from cœliac disease could be gauged, so I was obliged to feel my way cautiously, beginning with amounts which, no doubt, were too small, and perhaps even finally not reaching a sufficient dose. A child 6½ years old, weighing 21 lb., took 2 grains twice daily without any definite effect.

In one case, the girl aged 17½ years whom I have mentioned before, the administration of the chromo-santonin was followed by immediate improvement of the stools, which became less offensive and less loose, and there was rapid gain in weight.

In another, a girl aged 3¾ years, and weighing 15¼ lb., there was no marked alteration of the stools whilst the chromo-santonin was given—increasing doses up to 1 grain twice daily were used—but just after the course of this drug was stopped there was great improvement in their character; they became firmer and a better colour than they had been for months.

Clearly, further observations are needed on the value of this drug in cœliac disease. In the doses used it produced no ill-effects of any kind; the greenish-yellow discolouration of the urine due to santonin was observed in 15 hours after it was taken, but this is of no importance.

Dr. Begg considers that the chromo-santonin has a bactericidal action.

Intestinal Antisepsis.

Other drugs have been tried in this affection with the idea of intestinal antisepsis.

In one, at the age of about six years, iodoform gr. ½ was given for six months, apparently with markedly beneficial effect.

Salol has also seemed to do good.

Perhaps in the same category should be mentioned ionisation with sodium salicylate at one electrode; this was done in one case under my observation. A 2 per cent. solution of sodium salicylate was used on one pole on the abdomen. During this treatment, which was carried out for many weeks, the child very definitely improved, though she subsequently relapsed and died.

In one case I tried radium water; half a pint was given daily by mouth, without the slightest benefit.

In one of the recorded cases appendicostomy was done with a view to overcoming intestinal infection by irrigation through the appendix. Some improvement of the child's general condition started after this was done. Autopsy, however, showed that there was inflammation involving the whole of the small intestine as well as the large, so that it could hardly be expected that this treatment could do more than palliate symptoms.

Vaccine Therapy.

The discovery that a considerable proportion of the cases examined gave evidence of intestinal infection with a dysentery bacillus, as shown either by the finding of the organism in the stools or in the mucus from the bowel, or by the positive result with the agglutination test, naturally suggested that a vaccine might be of value.

I have used an autogenous vaccine of the dysentery bacillus in two cases where the bacillus had been obtained from the stools and a stock vaccine of dysentery bacillus where, although the organism could not be found in the stools, the agglutination test gave a positive result.

In both the cases where the autogenous vaccine was used there was very definite temporary improvement both of the stools and of the child's nutrition for about a fortnight, after which the condition again deteriorated in spite of continued use of the vaccine. The vaccine was administered in the one case in doses of 5 millions, increased gradually up to 200 millions; in the other the initial dose was 60 millions, increased later up to 150 millions.

In the third case, where only a stock vaccine was available, and was used in doses increasing from 25 millions gradually to 150 millions, no effect whatever was observed.

In one case where the dysentery bacillus was absent, but the stools showed many streptococci and pneumo-bacilli, a vaccine was used of pneumo-bacilli and streptococci in increasing doses up to 100 millions of each; no effect whatever, either for good or ill, was observed.

Internal Secretions.

The striking arrest of growth in these cases has raised a suspicion that one or other of the internal secretions might be deficient.

In three cases under my observation thyroid was given, but without the slightest advantage. It did not seem to promote growth nor to improve the general condition; indeed, one of them seemed rather the worse while taking it. This symptom is one for which treatment is specially sought in the cases which reach convalescence. The child herself is distressed by the difference between herself and those of her own age.

In one such case the administration of polyglandin, a preparation of mixed organic extracts, was followed by an increase of height of ⅜ inch in 14 days and another ¼ inch in the next 12 weeks, but the child at the same time had improved so much in her power of assimilation that she was able to take an ordinary diet in place of the restricted special diet, so that growth might have been due to this rather than to the drug.

If we have no certain means of promoting growth in these cases where it has been arrested by the disease I suspect that we can do something to prevent the stunting by the diet adopted during the earlier and more acute stage of the disease, for I have noticed that cases fed on human milk or on asses' milk have shown much less interference with growth than those in which such feeding was not obtainable.

Anyone who has seen the remarkable stunting of growth which can be produced in rats by regulating the diet so as to exclude some elements will realise that there is no necessity, in children with this disease, to seek for the primary cause of the arrest of growth in any failure of internal secretions. Nevertheless, it is quite conceivable that the general interference with nutrition, caused by the failure of fat absorption, may affect also the internal secretions which are known to play a part in the regulation of growth.

The point is one of practical importance. For if the arrest of growth is due simply to deficiency of calcium absorption, through the loss of calcium in the soaped fat passed in the fæces, one might suppose an increase of the intake of calcium by administration of calcium salts—for instance, the lactate or the chloride—would compensate to some degree for the loss in the fæces, assuming that the wastage in the form of soap remains unaltered.

But I know of no evidence that growth is promoted by the giving of calcium in this way; I am not even satisfied that calcium salts given thus have any effect upon bone formation; certainly one's experience is that, judging from clinical evidence, calcium in the form of lime-water has little, if any, effect in the prevention or in the cure of rickets. Moreover, in some experiments upon the feeding of rats with a diet deficient in fat, the arrest of growth occurred in spite of the administration of calcium in the form of calcium lactate.

IMPORTANCE OF DIET.

To sum up, it would seem that drugs, while not entirely impotent in the treatment of this condition, have a very limited scope, and that chief reliance is to be placed upon scrupulous care in dieting. The element in the food which requires most consideration is the fat, and the form of fat which seems most obnoxious to children affected with cœliac disease is the fat of cow's milk. If this be borne in mind it is nearly always possible to obtain marked improvement in these cases, and a large proportion of them can be coaxed back after many months or years of patient perseverance with a very restricted diet, to health and even to an average power of assimilation.

CONCLUSION.

In conclusion, Gentlemen, I can only regret that I have not been able to throw more light upon the obscure problems raised by this group of cases, and that the working hypothesis with which I started, that it can be pigeon-holed as one specific morbid entity, cœliac disease or intestinal infantilism, name it what you will, remains still nothing more than a working hypothesis.

I have raised many questions, I have answered few, and if any apology is needed, I would say, in the words of Heraclitus, *χρυσόν οἱ διζήμενοι γῆν πολλὴν ὀρύσσουσι καὶ εὑρίσκουσιν ὀλίγον.*

THE TREATMENT OF WOUNDS.

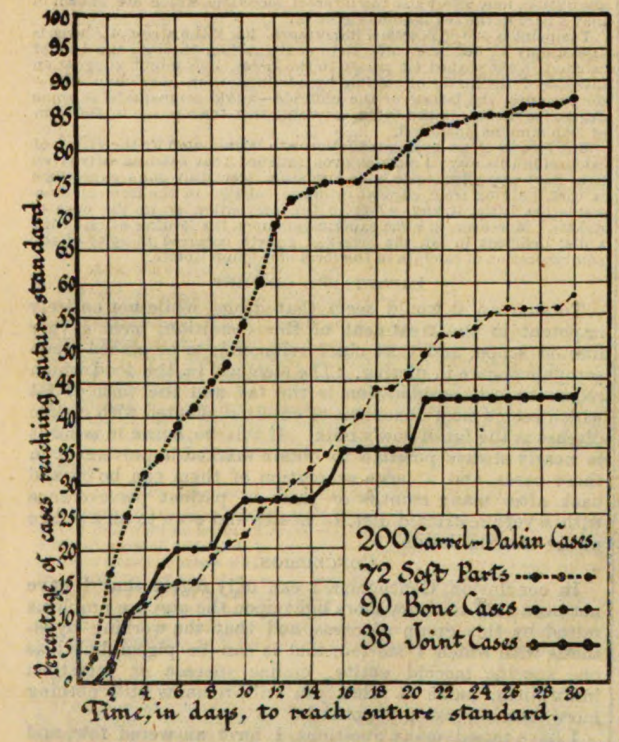
BY JOHN T. MORRISON, F.R.C.S. ENG.,
J. N. J. HARTLEY, F.R.C.S. EDIN.,
AND
E. F. BASHFORD, M.D. EDIN.,
CAPTAINS, R.A.M.C. (T.C.).
(*From the Surgical Observation Hut, attached —— General Hospital.*)

I.—THE CARREL-DAKIN TREATMENT OF WOUNDS: REVIEW OF 200 CASES.

DURING 1916 and 1917 a large number of cases were treated by the Carrel-Dakin method; detailed notes were kept, but for months at a time this was out of the question and no more than 200 form the basis of this paper. The first 100 were cases treated in a base hospital in the wards devoted to the most serious cases; the second 100 in the surgical observation hut attached to a general hospital. These last consist of severely wounded men, moribund cases being excluded. The following indicates the type of wounds dealt with:—

Wounds of soft parts, 37 per cent.
Compound fractures, 46 per cent.: Humerus, 9 per cent.; ulna and radius, 4·5 per cent.; femur, 6·5 per cent.; tibia and fibula, 11 per cent.; other bones, 15 per cent.
Wounds of joints, 17 per cent.: Shoulder, 4 per cent.; elbow, 2 per cent.; wrist, 2 per cent.; knee, 6·5 per cent.; ankle, 2·5 per cent.

Results vary greatly according to whether preliminary surgical treatment is undertaken in the pre-inflammatory period or after sepsis is established. The cases have therefore



been divided into (A) those operated on within 24 hours, and (B) those without preliminary operative cleansing, or in which this was not done till at least 24 hours had elapsed. More scientific classification is impossible; cases falling into Class B are becoming fewer and fewer.

Results.

The combination of mechanical cleansing with progressive sterilisation by means of a chemical agent has brought about an extraordinary advance in wound treatment, and evidence will be put forward which cannot fail to convince any who have had to deal with wounds since the earlier stages of the war. The evidence consists of a careful record of 200 cases typical of the ordinary severe injuries passing through any base hospital in France. The accompanying table shows the main results:—

	A, 114 cases.	B, 86 cases.
Temp. normal ...	in 95·9% after 9·7 days* ...	in 86·3%, after 8·2 days.
Suture standard reached in ...	,, 82·5% ,, 12 ,,	,, 67·4% ,, 15·5 ,,
Suture performed	,, 77·5% ,, 13·6 days ...	,, 53·5% ,, 17 ,,
Healed before evacuation...	... 67·5% of cases ...	44·2% of cases.
Average duration of treatment before healing ...	... 28·2 days	33·6 days.

Case mortality, 3%. Secondary hæmorrhage, 3%. Secondary amputation, 3%.

* In each case after treatment for number of days indicated.

The accompanying chart is instructive inasmuch as it shows the relative speed at which wounds of soft parts, bones, and joints attained suture standard.

Such facts speak for themselves and there is no doubt that similar results can be obtained by any who are familiar with the technique and apply it faithfully.

Treatment.

Treatment has followed closely on the lines laid down by Carrel. It has been possible to treat patients from the commencement in only a few instances and accordingly reliance had to be made for the early treatment on some unknown member of the profession working in an unknown casualty clearing station. This opportunity may be taken of saying how efficient that treatment is becoming in the great bulk of cases. In a series of close on 300 over 10 per cent. reached the base in a condition enabling suture précoce to be practised at once.

The main outlines of the Carrel treatment are now well known to surgeons in France; one or two points, however, must be alluded to.

Attempts at excising a wound in which the infecting organisms have already invaded the tissues do not hasten recovery, and at the same time materially increase the risk of septicæmia. In these cases operations should be limited to such incisions as are necessary to expose freely the furthest recesses of the wound, and the removal of such tissue only as is obviously necrotic.

In the pre-inflammatory stage, however, a radical operation secures the best results. Long incisions give a better chance of seeing and removing all contaminated tissues, and when it comes to closing the wound long incisions are just as easy to suture; they should always be planned, of course, to facilitate secondary closure. Partial closure of wounds at the primary operation almost always postpones the date of complete healing.

When a case treated by the Carrel-Dakin method arrives at the base the injection of the tubes is carried on until the patient is seen by the surgeon.

If the patient is comfortable and the pulse and temperature satisfactory, we are in no hurry to change the dressings. After 48 hours at the most, however, the bandages are removed and the superficial dressing at least changed. The skin is gently cleaned with neutral sodium oleate soap solution to which 2 per cent. chloramine-T is added and then covered with strips of bandage impregnated with sterile vaseline. If at this stage the general condition is good and the wound is free from pus and sloughs visible to the naked eye, smears and cultures are made from the parts most likely to give trouble, such as bone, fascia, tendon sheaths, or deep pockets. If the smears are satisfactory—i.e., not more than one organism per field, or one diplococcus in three—the wound is sutured next morning. If, however, the wound is not up to suture standard the Carrel-Dakin treatment is continued.* The essence of this treatment is to supply to every portion of the wound surface hypochlorite solution at stated intervals and to keep the solution as long as possible in contact with the surface. In order that every portion may be reached each wound must be studied separately and the tubes chosen must be suitably perforated. Individual recesses, if important, must each have a tube, or, if unimportant, a wick of gauze or lint. The influence of gravity must be taken into account in disposal of tubes. The original petticoated tube has been almost entirely given up. Lint is used in the dressing to a large extent instead of gauze.

Operative measures are undertaken only in response to some urgent indications during the first ten days.

* The results obtained by the surgeons in Depage's clinique go to show that in the presence of streptococci early suture—suture précoce—is not justifiable. A large number of observations have been made along these lines, but they are not yet sufficiently far advanced to show just what organism it is dangerous to leave in a sutured wound; even the streptococci are not uniformly pathogenic.

Removal of foreign bodies not giving rise to acute symptoms, of small pieces of badly infected bone, and secondary operations of all kinds are done, if possible, only when local reaction is well established and, as far as may be, after the general wound surface has reached suture standard. When infected bone is not essential to the ultimate usefulness of the part a portion is freely resected, but function is never sacrificed to secure early asepsis. Of the fractures of long bones included in this series which were retained for five weeks or more 82·5 per cent. were already consolidated. After eight weeks only 5 per cent. remained ununited.

Fifty consecutive cases were treated with eusol. Two-thirds of these were A cases and one-third B cases. The results were as follows:—

Temperature normal after treatment for 10·9 days in 92 per cent.
Suture standard reached after treatment for 15·9 days in 78·1 per cent.
Suture performed after treatment for 17 days in 70·9 per cent.
Healed before evacuation, 70·9 per cent.
Average duration of treatment before healing, 30·9 days.

Injection of Solution.

The solution has been prepared according to Daufresne's modified formula and carefully standardised. It has been injected into the tubes every two hours, either by a hand syringe or from an ampoule. The hand syringe is the only method at present in use which ensures that each tube gets its full dose every time. Nevertheless, the labour saved by the ampoule is very great, and the distribution of fluid is fairly uniform if the following points are attended to:—

1. Ampoule should be suspended as vertically as possible above wound.
2. The use of Y-shaped glass junctions is preferable.
3. The main tube of a three- or four-way glass connexion should be kept as horizontal as possible. This can often be secured by safety-pin attaching it to bandage.
4. The tubes should be inspected at intervals to make certain that none are kinked.

If the solution be injected into each individual tube by a syringe the free ends of the tubes should be gathered together and closed with a clamp after injection. Two squirts and two vessels containing Dakin's solution are all that are needed. While one is being used to inject the tubes of the first patient the other stands full of solution in the second vessel, and is thus sterilised ready for next patient.

The question of heating the hypochlorite solution has always been a vexed one. Observations show that the deterioration, judged by chemical standard, is inappreciable after addition of an equal volume of hot water at 90° C. to Dakin solution 1·043 per cent. In cold weather there has never been any hesitation in using this solution warmed to body temperature by diluting, as above.

The amount of fluid used varies according to the wound and number of tubes, but an average of 10 c.cm. per tube every two hours does not lead to overflow into bed. There should be a square of mackintosh under wounded part. A useful precaution also is to have a sphagnum-moss pad applied to dependent part of wounded area outside all the bandages.

Two hours has been chosen as the routine interval between injections, and experiments undertaken confirmed this practice. However, where pus is present the renewal of the fluid every hour is advisable.

Comparison with Other Methods.

The results recorded speak for themselves, but many of the cases which on paper look like failures really represent limbs saved and function preserved. The proportion of really successful cases (that is, where secondary suture in the first 10 to 12 days permits practically of a return to normal) is higher far than that attained under any other treatment thus far tested. Definite figures can only be quoted for cases treated by hypertonic saline, flavine, and dichloramine-T in eucalyptol. These figures should be contrasted with those under the heading Carrel-Dakin B for the reason that though given surgical treatment at the front they did not receive the special treatment till after arrival at the base.

Carrel-Dakin, A	77·5%	closed by suture.
,, ,, B	53·5%	,, ,,
Dichloramine-T (in eucalyptol) ...	43·0%	,, ,,
Flavine	22%	,, ,,
Hypertonic saline	12%	,, ,,

The only other method giving results at all comparable is that of early operation and primary suture with or without the use of brilliant green, bipp, flavine, soap, or other fashionable adjuvants.

[The disadvantages were here considered.] Most of the criticisms involve no insuperable difficulty. They are questions of management, possibly self-sacrifice. The plea that the method has difficulties should not weigh for a moment when the safeguarding of life, limb, and a man's future happiness and usefulness are considered. It is not too much to say that the very least which we can do for the wounded man is nothing short of our very best.

II.—A STUDY OF 50 CASES TREATED BY DICHLORAMINE-T IN EUCALYPTOL.

Dichloramine-T (or toluene-para-sulphondichloramide) (Dakin [5]), a substance closely related to chloramine-T and very like it in its antiseptic properties, is, however, very sparingly soluble in water and freely soluble in various oils. Thus it was hoped by means of an oily solution to provide a reservoir from which the antiseptic in the watery fluids of the wound could be maintained at an adequate concentration from one dressing till the next. Dichloramine-T, though resembling the hypochlorites in its germicidal action, differs in many other respects. Dakin showed that the chloramines have very little disintegrating effect on necrotic tissues. Further, dichloramine-T is a powerful coagulator of albumin, and even in a strength of 1–5000 precipitates some of the albumin present in serum. It was with the object of determining the value of the dichloramine-T in wound treatment that the following clinical study was undertaken.

Results of Investigation.

Persistence of the antiseptic action.—That the antiseptic passes slowly from the oily medium on to the wound surface can readily be demonstrated by the starch iodide test. A bacteriological method was also employed to throw light on this point.

Dichloramine-T 2 per cent. dressing, even if not still detectable by the available chemical tests, at least made its influence felt for about 12 hours in a lightly infected wound. Experiments on more heavily infected wounds showed less satisfactory results. In some cases the growth was quite as heavy within four hours as it had been before the application of the dressing. Nevertheless, the facts suggest that dichloramine-T in oily solution is a step in the right direction in so far as prolonged antiseptic activity on a wound surface is regarded as desirable.

In order to compare the dichloramine-T oil method with others in the actual treatment of wounds 50 consecutive cases arriving at the base with infected wounds were put under this treatment.

They were cases of gunshot wounds of varying severity; about half had bone injury. They were very closely comparable to the series of cases treated by flavine recently reported by us,[6] the results of which are here repeated for comparison, as also are those for a similar series of cases treated by the Carrel-Dakin method. It must be stated that practically every case in the flavine and dichloramine-T groups had had the benefit of early operation, followed by one or other established method of treatment—mostly bipp or Carrel-Dakin. Treatment by dichloramine-T was not started, however, till arrival at the base, anything from two to six days from infliction of wound.

Technique.—As a routine the 2 per cent. solution of dichloramine-T, as originally recommended by Dakin, was employed in this series. A stock of 12 per cent. in chlorinated eucalyptol was kept, and each day a sufficient quantity was diluted down with chlorinated paraffin. The stronger concentrations were not used, partly because it was found that the duration of the antiseptic action was not thereby materially increased, but chiefly on account of their deleterious effects as described later. The wounds were dressed daily with loose packs of lint wrung lightly out of the dichloramine-T oil, every effort being made to reach all parts of the wound surface. Where necessary the wound was further opened up to make this possible; otherwise surgical interference was restricted to a minimum, especially during the first ten days. In certain cases where there was much purulent discharge a piece of tubing was employed to renew the solution in the deepest part of the wounds every 8 or 12 hours.

Clinical results.—When judged from the standpoint of ordinary clinical experience the wounds as a whole could be described as doing well, passing fairly quickly through the usual stages. Sloughs separated and granulation of a moderately bright red colour soon appeared. Pus formation as a rule was comparatively small, and spread of infection to surrounding parts was not common. Epithelial growth at the skin margins was somewhat slow. Despite the good appearance of the wounds it was observed that many did not attain the bacteriological suture standard. In a few cases these were closed, with, however, no greater percentage of successes than is usual when wounds are closed upon clinical grounds without reference to the bacteriological control.

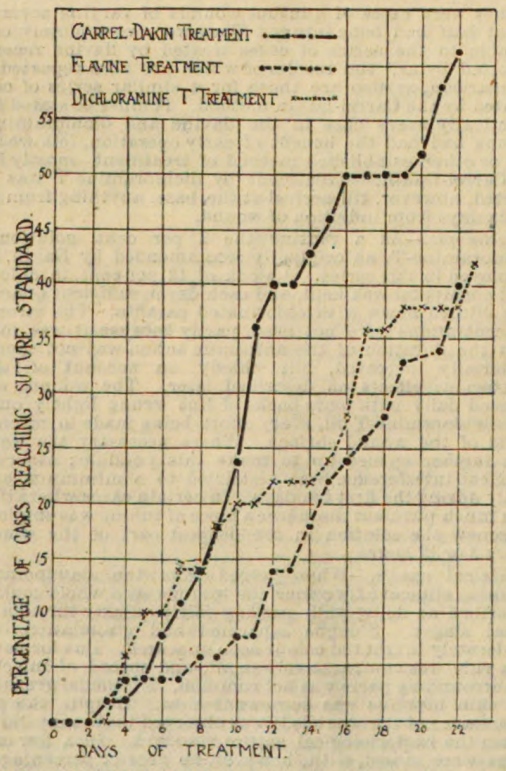
A troublesome complication which occurred very frequently was the skin irritation around the wound. In 24·5 per cent. of the cases there were œdema, redness, formation of papules, and sometimes blistering and excoriation, while in 10 per cent. the treatment had actually to be abandoned on that account. The irritation could only be controlled by diminishing the quantity used, and to a less extent by protecting the skin around by strips of bandage cloth permeated with vaseline. The authors have met certain surgeons who declare they have had little or no skin irritation from the use of dichloramine-T. These surgeons, however, have been found to use only minimal amounts of the solution, either with a spray or by dressings wrung dry before application. Experiment goes to prove that such small quantities of this antiseptic are very evanescent in their action. It has been stated lately that by the use of a chlorinated paraffin wax (chlorcosane) as a solvent for the dichloramine-T the skin irritation is greatly diminished, but as to that we have no experience.

Results Obtained by Dichloramine-T Oil, Flavine, and Carrel-Dakin Methods.

—	Dichloramine-T.	Flavine.	Carrel-Dakin.
Total	53	50	50
T. normal in...	94% after 6·4 dys.	86% after 8·8 dys.	94% after 11·7 dys.
Suture standard reached in ...	48% after 16 dys.	38% after 15·6 dys.	68% after 12·5 dys.
Sutured	44·2% after 17·2 days.	34% after 17 dys.	54% after 14·9 dys
Healed	38% after 32·4 dys.	22% after 26·5 dys.	56% after 28·6 dys.
Mortality... ...	Nil.	Nil.	Nil.
Secondary amputations ...	2%	2%	4%
Secondary hæmorrhage..	Nil.	4%	Nil.

The results obtained by dichloramine-T, though better than those in the flavine group, fell behind those in the Carrel-Dakin series. The average date at which the temperature became normal was earlier in the dichloramine-T series, but the cases in the Carrel-Dakin series, as a whole, were more serious. Several cases considered too serious for the trial of a new method were added to the Carrel-Dakin series. Yet the Carrel-Dakin series shows 20 per cent. more cases sutured and 32 per cent. more healed before evacuation than in the dichloramine-T oil series.

The relative speed at which the wounds in the various series reached suture standard will be best appreciated by the following Chart:—



Graph showing relative rapidity with which septic wounds treated by various methods reached suture standard.

Histology.—Portions of granulation tissue with the adjoining skin edge have been excised from the series both of cases that came up to suture standard rapidly and in which this was delayed or not reached. They were excised at intervals varying from 3 to 30 days, and after treatment with the different concentrations. Dichloramine-T dissolved in chlorinated paraffin eucalyptol in a concentration of 2 per cent. induces an evident reaction both on the skin and granulation tissue, which can, however, only be recognised as certainly deleterious after prolonged application. This is due either to the action of the free chlorine given off or the essential oil or to both, and occurs more rapidly and is more marked with higher concentrations. It ultimately leads to delay in the processes of healing, the ingrowth of skin epithelium becoming aborted and the formation of scar tissue irregular and imperfect. With higher concentrations these changes are exaggerated.

Conclusions.

The dichloramine-T oil method of wound treatment is simple of application, and the claim that the action of a single application is prolonged is substantiated. The results, even when judged by modern standards, are not to be disregarded.

Dichloramine-T oil is not indifferent to granulation tissue or to the skin edges of wounds, but has, especially if used for a long time, a deleterious action on both. The ingrowth of skin is retarded, and the natural tendency for granulation tissue to disorganisation is aggravated.

The use of an oily menstruum does not altogether prevent the adhesion of dressings to the surface or obviate the repeated, if minute, insult to the tissues inseparable from each dressing.

Though an improvement on some other methods in vogue, dichloramine-T oil has not yielded the improvement on Dakin's solution that was anticipated, perhaps because it is neither innocuous to healthy granulation tissue, nor a solvent of dead tissue, perhaps, possibly, because an oily application is not so efficacious as a watery solution in the treatment of wounds.

POST-DIPHTHERITIC PARALYSIS.

NOTE ON A FORM FOLLOWING CUTANEOUS DIPHTHERIA.

BY F. M. R. WALSHE, M.D. LOND., M.R.C.P. LOND.,
MAJOR, R.A.M.C.; CONSULTING NEUROLOGIST, E.E.F.

Introduction.

THE nervous sequelæ of diphtheria constitute a very characteristic symptom-complex. The initial palatal paralysis and the striking symptoms it occasions, the affection of accommodation, and the frequent polyneuritis are familiar to all clinical observers.

The mode of development and the topography of this condition are commonly regarded as dependent on a selective action of the diphtheria toxin on certain cranial nerves and their nuclei; that is, on a selective hæmatogenous toxæmia of the nervous system.

However, when experimentally produced in animals diphtheritic paralysis is not characterised by the cranial nerve involvement so typical of the condition in man, and this fact has led certain observers (C. Bolton, Crocq) to postulate specific differences in the action of the toxin in man and in animals respectively. Thus, Bolton [1] concludes—

"That in the higher mammals the poison especially attacks the medullary centres and the cranial nerves, and in the lower mammals the spinal centres and spinal nerves."

In a comparative analysis [4] of the factors concerned in the production of diphtheritic paralysis in man and animals I have sought to show that a simple physical factor—namely, the seat of toxin formation—is an adequate explanation of these apparently specific differences. For it is noteworthy that in man the structures initially, and frequently alone, paralysed are closely related anatomically to the infective focus in faucial diphtheria, not only in the matter of actual proximity, but, and as Orr and Rows [2] have shown this is far more significant, in that of innervation. For the afferent innervation of tonsils and fauces and the motor nerve-supply of the palatal muscles are both part of the glossopharyngeal-vagus-accessorius nuclear system and its peripheral nerves.

In animals a similar anatomical correspondence between the evolution of the paralysis and the site of the experimental infective lesion is seen.

Aubertin, Babonneix, and Guillain and Laroche have all drawn attention to this significant relationship between primary lesion and initial paralysis. On the other hand, several observers (Remak, Oppenheim, Bolton, and Brewer) record the absence of palatal involvement in certain cases of paralysis following extra-faucial diphtheria.

These exceptional instances, however, do not appear to have determined any change in the current view that the underlying process is a selective blood-borne intoxication of the nervous system. If this hypothesis be correct, the syndrome of diphtheritic paralysis should be independent of the site of the infective focus and relatively constant in type. If, on the other hand, as Guillain and Laroche have suggested, we are dealing with an ascending neuritic process comparable with that occurring in tetanus, the study of the nervous sequelæ of extra-faucial (wound and cutaneous) infections should reveal the anatomical relationships mentioned above, and at the same time help to elucidate the pathogenesis of diphtheritic paralysis. To an adequate appreciation of the problem a consideration of the work of Orr and Rows [2] on "lymphogenous toxi-infections of the nervous system" and that of Meyer and Ransom [3] on tetanus is an essential preliminary.

Clinical.

During the past 15 months (1917–18) there has been an unusually favourable opportunity for the clinical study of this question. A form of localised superficial cutaneous ulceration on hands, forearms, and other exposed parts known as "septic sores" has been extremely prevalent among troops in this field of operations (E.E.F.). Occurring simultaneously has been an outbreak of faucial diphtheria of a relatively mild type, but associated for reasons inseparable from active service conditions with a large proportion of nervous sequelæ of the usual character.

In these circumstances a large number of cases of polyneuritis were observed, not associated with any previous illness, and under conditions in which beri-beri, arsenic, alcohol, and other causal factors could be excluded, but definitely connected with "septic sores," infected cuts and wounds. They gave no history of sore-throat.

An analysis of a series of these cases revealed three constituent elements in the fully developed symptom-complex; a local paresis related to the infective focus, when this was not multiple, a paralysis of accommodation like that seen after faucial diphtheria, and a polyneuritis. Of these three elements, the local paralysis occurred in 27 per cent. (8) of a series of 30, the paralysis of accommodation in 33 per cent. (10), while the polyneuritis was constant.

The local phenomena were associated in 6 cases with a single infective focus, the remaining 24 of the total showed multiple "septic sores."

In the majority of the observed cases the cutaneous lesions were healed when nervous symptoms appeared, but in 6 bacteriological examination revealed in pure culture an organism morphologically and culturally indistinguishable from the Klebs-Löffler bacillus.

In one of these the source of infection was a fatal case of laryngeal diphtheria. A résumé of this particular case will stand as a fair example of the series, though in it there was no ocular defect and constitutional symptoms were unusually severe.

A medical officer in performing tracheotomy on a case of laryngeal diphtheria scratched his right thumb; a small ulcer appeared from which the diphtheria bacillus was grown. During convalescence numbness and paræsthesiæ of the right thumb, weakness and clumsiness of hand movements, and cramp in hand and forearm muscles developed, and preceded a typical polyneuritis of moderate severity. At no time were any palatal symptoms noted.

The local onset related to the infective focus was an early and prominent feature of this case.

In considering the much greater frequency of a local onset in faucial diphtheria, there must be borne in mind the much shorter course of the peripheral nerves in this instance, a factor which, as Orr and Rows have shown, largely determines the intensity of the central nervous lesion. Yet even after faucial diphtheria a certain proportion of cases of polyneuritis are seen preceded by no local phenomena.

In all over 50 cases of this type were observed, and for the following reasons, it was concluded, might confidently be regarded as post-diphtheritic:—

1. Their association as to time and place with the occurrence of faucial diphtheria.

2. The isolation with considerable frequency, by pathologists in the field and at base laboratories, of organisms morphologically and culturally indistinguishable from the Klebs-Löffler bacillus, from the type of cutaneous lesion with which these cases were unquestionably associated. In addition, their isolation in six observed cases of polyneuritis.

3. The occurrence of paralysis of accommodation as a symptom—this being peculiar to post-diphtheritic paralysis.

4. There was evidence of a time relationship between development of primary lesion and neuritis; the latter appearing from the fourth to the sixth weeks of infection in such cases as afforded indications of onset of infection.

5. The absence of any other known causal agent.

The Pathogenesis of Diphtheritic Paralysis: A Comparison with Tetanus.

The resemblances between this symptom-complex, with its three elements, and the modern conception of tetanus we owe to Meyer and Ransom will be at once apparent. The local, specific, and generalised forms of tetanus may be compared with the local, ocular, and generalised phenomena seen in these cases.

While the theory of a selective hæmatogenous intoxication may account for both generalised and ocular (specific) symptoms in post-diphtheritic paralysis, it is inadequate to explain the local phenomena with their varying incidence in faucial and extra-faucial diphtheria. The following hypothesis may therefore be put forward to account for the processes underlying the genesis of diphtheritic paralysis. This has been more fully discussed elsewhere,[5] but may be briefly resumed thus:—

The initial local paralysis is the result of a "lymphogenous" intoxication (Orr and Rows) of the nervous system, the toxin being carried from the infective focus along the perineural lymphatics to the corresponding cranial or spinal centres. In the case of faucial diphtheria the palatal musculature being innervated from the cranial nerve concerned is earliest affected.

The specific (ocular) and generalised (polyneuritic) symptoms cannot be accounted for thus, but must be due to the toxin circulating in the blood stream and thus reaching the whole nervous system, central and peripheral, simultaneously. Accommodation paralysis may be regarded as the manifestation of a selective affinity of the diphtheria toxin for certain elements of the nervous system, while the polyneuritis is the expression of the general toxæmia of the nervous system.

The analogy with tetanus does not extend to the underlying pathological processes; diphtheria toxin is not so specific in its action as is tetanus toxin, and the ascending lymphogenous process suggested here is not peculiar to diphtheria, but occurs with numerous other toxins and organisms (Homéo, Guillain, &c.).

Viewed in the light of this hypothesis, the obscurity surrounding the question of the essential nervous lesion in diphtheria largely vanishes. A pathological and experimental confirmation of this clinical hypothesis on the lines indicated in the work of Orr and Rows is clearly needed. The inconclusive results of past investigations of this nature may be traced to the absence of any clear or guiding conception of the nature of the processes involved in the production of diphtheritic paralysis.

Appendix.—At the Neurological Section of the Royal Society of Medicine on Feb. 21st, 1918, Dr. Henry Head showed a case of "toxic polyneuritis of the trenches." This man, it is recorded, was "treated for boils" at or about the onset of his nervous symptoms. It is worthy of consideration from the point of view now presented.

ROYAL FREE HOSPITAL.—A grant of £10,000 has been made to the Royal Free Hospital by the American Red Cross Commission for Great Britain for an extension of the maternity department, and it has been decided to take over and extend the maternity hospital hitherto entirely supported by the Duchess of Marlborough which at present provides for the treatment of 20 patients. It is intended, as soon as the necessary arrangements can be carried through, to provide 50 beds for maternity cases. It is also intended to extend at this centre maternity training for the nursing staff of the Royal Free Hospital and other pupils. The spirit which has animated the representatives of the American Red Cross Society in making this grant is keenly appreciated by English medicine.

THE TREATMENT OF STAPHYLOCOCCAL INFECTIONS BY STANNOXYL:

"MIXED INFECTION" OF PULMONARY TUBERCULOSIS.

BY ARTHUR COMPTON, B.A., M.B. R.U.I., D.Sc. N.U.I.,

CAPTAIN, R.A.M.C. (TEMPORARY); OFFICER IN CHARGE, BACTERIOLOGICAL LABORATORY, DORSET DISTRICT; FORMERLY RESEARCH ASSISTANT, INSTITUT PASTEUR, PARIS.

IN a previous communication [1] I gave an account of the first cases in this country of furunculosis and acne treated by the new drug stannoxyl, recently put forward by Frouin and Grégoire,[2] as a specific for staphylococcal infections. So far the employment of stannoxyl with successful results in staphylococcal infections has been recorded only for furunculosis (Frouin and Grégoire,[2] Hudelo,[3] Compton [1]), acne (Frouin,[4] Compton [1]), chronic suppuration of bone (Grégoire and Frouin [5]), traumatic osteomyelitis (Phocas [6]), suppuration in gunshot wounds (Phocas [6]).

In view of the fact that the staphylococcus is more or less constantly met with in the microbial flora constituting the "mixed infection" of pulmonary tuberculosis, it has occurred to me to test the influence of stannoxyl on this condition. The present paper deals with three clinically definite cases of phthisis so treated, a short preliminary account of which has already appeared elsewhere.[7] The stannoxyl for the investigation was kindly placed at my disposition by M. Frouin.

Broncho-pneumonia (? Tuberculous).

CASE 1.—Pte. L., aged 23, half-caste Australian aboriginal. Sent back from France on Feb. 17th, 1917, suffering from pleurisy; left side affected. Admitted to hospital at Norwich, where he stayed five weeks, from which he was sent to Dartford, where he remained eight weeks. Arrived eventually at Weymouth in May, 1917, feeling pretty well. Next comes a history of three or four days' pain in chest on right side; cough, with frothy expectoration (no blood), and a difficulty in keeping his food down. Readmitted to hospital May 29th, with the provisional diagnosis of tuberculous broncho-pneumonia. Moist sounds scattered throughout the chest, with harsh breathing at both apices. Following admission, morning temperature was 100–101° F., evening temperature 102–103°; pulse 100–140 per minute; respiration 32–40 per minute. Tepid sponging was practised throughout June to control the temperature.

First seen by me about July 10th, when, with the idea of clearing up the "mixed infection"—on the assumption that the case was tubercular, which it was clinically—and, thereby, bringing down the temperature, stannoxyl treatment was begun. Frequent examinations of sputum for T.B. were carried out over the period May 30th to August 16th; but T.B. were never found; the pneumococcus was constantly found. The bacteriological findings in regard to a specimen of sputum of July 2nd, examined by culture on serum-agar for the presence of staphylococci, were as follows: No staphylococci isolated; but colonies of three sorts of Gram-negative bacilli, one being Friedländer; also a Gram-negative diplococcus. Another specimen of sputum was examined from this point of view on August 7th, when *Staphylococcus albus* was found to be present.

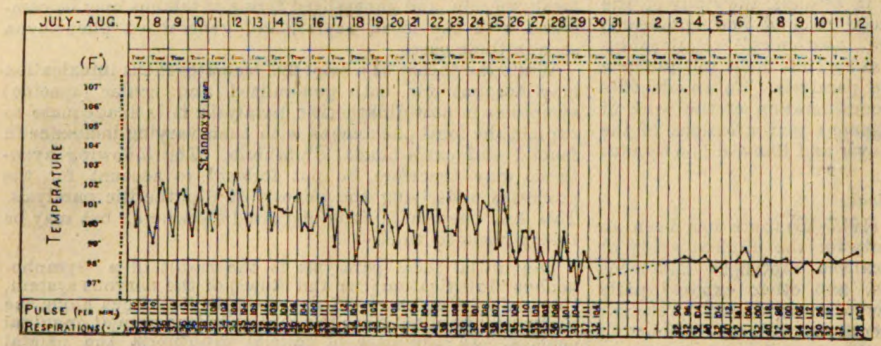
Chart 1 indicates the progress of the case from the time stannoxyl treatment began, or just a little previous to this, until the temperature became normal and remained thereafter at or about the normal level. The dotted portion of the chart between July 30th and August 3rd corresponds to a missing temperature chart, unfortunately lost during a change of hospital.

Only four stannoxyl tablets (about 1 g.) were taken per day at the commencement of treatment, and sometimes even less, as the patient was so ill, and one was uncertain what the effect of the stannoxyl might be. Indeed, on July 19th, his condition was so bad that an injection of pituitrin had to be resorted to.

Seventeen days after treatment with stannoxyl had begun the temperature fell sharply to or about normal, and remained so until his discharge from hospital on Sept. 7th to return to Australia. Although still in a weak condition at the time of his discharge his temperature, with the exception of evening rises to 100·8° recorded on three occasions, had only oscillated 0·5° on either side of the normal all through August; his pulse-rate had become on the average 94, his respirations 26; the amount of sputum expectorated had greatly diminished; his appetite had become good, and his general condition had altogether improved, the patient being able to get up and move about his ward a few hours daily.

Before his departure he was taking regularly eight tablets of stannoxyl per day.

CHART I.



Pulmonary Tuberculosis.

CASE 2.—Private W., aged 19. Joined the Army in January, 1917. He caught a cold in February during his training in a camp at Ripon; when he had a cough and frequently spat up blood; but he did not report sick to his medical officer. The cough eventually passed off, and he arrived in France in June, 1917. He was wounded at Ypres on August 15th by a bullet in the left forearm, which necessitated amputation of the arm. He was sent to Boulogne, where he remained in hospital a few days, and was eventually transferred to Weymouth, arriving here on August 28th. He then had a cough and complained of always sweating (chiefly in the daytime). His physical signs at this time (examination Sept. 4th) were: Right lung, in front, dullness and bronchial breathing at the apex; behind, crepitations scattered all over the lung. Left lung, in front, breathing good at the apex, dullness and crepitations over lower lobe; behind, dullness, especially at the base, bronchial breathing at the level of the spine of the scapula, and coarse crepitations at the base. A specimen of sputum examined on Sept. 6th revealed the presence of T.B.

Stannoxyl treatment was begun on Sept. 8th, 4 tablets (1 g.) being taken the first day, 6 the second, and 8 per day ever since. Chart 2 gives a graphic representation of the progress of the case, showing the response to treatment.

Systematic examinations of sputa were carried out during the course of treatment, to ascertain the effect in vivo of stannoxyl on the microbial flora constituting the "mixed infection." Table I. resumes the findings.

During the fourth week of treatment, as Chart 2 indicates, the temperature fell to normal, and after oscillating for a fortnight more or less widely about the normal eventually ran a subnormal course for three weeks before settling down about Nov. 7th to oscillate less than 0·5° on either side of the normal. At the same time the pulse- and respiration-rates improved, the quantity of sputum became less, the appetite became very good, and the patient visibly put on flesh. The physical signs also showed improvement, as the following examination of Nov. 9th shows: Right lung, at the apex, dullness, prolonged expiration but no crepitations in front; behind, dullness, prolonged expiration, and some crepitations on deep inspiration; lower lobe, breath sounds not very clear, but no crepitations. Left lung, breathing normal.

Since Sept. 29th the patient began to get up, and that no doubt is the explanation of the rise of temperature of that date. Since Oct. 6th he has been going out every day for a short walk.

CASE 3.—Private D., aged 19. Joined the Army in November, 1916. Admitted to hospital on August 30th, 1917, complaining of "tightness in the chest and cough." For the few days following admission his morning temperature was 100–101° F., and that of the evening 102–103°; pulse-rate 88–110, and respiration-rate 22–24. Physical examination on Sept. 7th revealed marked dullness at the right base, diminished fremitus and vocal sounds, with deficient air entry. A sputum examination of Sept. 9th showed the presence of a few tubercle bacilli, while this was confirmed in a second specimen of Sept. 13th, in which more bacilli were found. On Sept. 24th there was marked dullness in the right axillary space extending from the fifth to the eighth ribs, vocal resonance and tactile fremitus were diminished, and the breath sounds were distant; the patient had profuse night-sweats.

Stannoxyl treatment, as indicated on Chart 3, was begun on Oct. 2nd, and throughout the treatment numerous bacteriological examinations of the patient's sputum were carried out to ascertain the effect of the treatment on the flora constituting his "mixed infection." Table II. indicates the findings.

Two weeks after his having been put on stannoxyl we find the temperature reduced to normal, or rather subnormal, in which region it remained more or less until his discharge from hospital on Oct. 30th. He was discharged on this date to proceed to a sanatorium, since when he has been lost to view.

In addition to the patient's temperature becoming normal under the influence of the treatment, his general condition showed almost daily improvement. His night-sweats disappeared, his sputum became markedly less, his pulse- and respiration-rates became more nearly normal, and he was rapidly putting on flesh, having gained 8 lb., as indicated on Chart 3, between Oct. 11th and 25th. He had been getting up ten days and had been taking walks outside five days previous to his discharge from hospital.

Remarks.

These three cases—one of broncho-pneumonia (? tubercular) and the other two of pulmonary tuberculosis—are of particular interest. As cases they constitute a record of the first attempt, so far as I am aware, to combat by means of stannoxyl the "mixed infection" of pulmonary tuberculosis—infection long recognised as the agent responsible for the temperature and which really kills and carries off the patient in phthisis.

In all three cases under the influence of stannoxyl treatment the temperature sooner or later fell to the region of normal; in three weeks for the first, in four weeks for the second, and in two weeks for the third. At the same time, a corresponding improvement occurred in the general condition; the pulse and respiration rates became more nearly normal, the sputum expectorated steadily became less, the appetite improved, and the patients put on flesh.

Considering, therefore, the results achieved in the above three cases, out of five which I had at my disposition for the investigation, the publication of their notes to-day seems justifiable. The other two cases, in a dying condition when first seen by me and put on stannoxyl, did not survive long enough to permit of the drug having a fair trial, their disease carrying them off within a week of the commencement of treatment. Case 1 has for the time being been lost sight of, owing to his discharge from the army and return to Australia; as also Case 3, having been discharged to a sanatorium. Case 2 is still under observation and treatment.

These therapeutic studies, and those already published on furunculosis,[1] constitute a complete confirmation of Frouin and Grégoire's original in vitro observations.[2] The more the conditions of culture in the body are anaerobic, the more the stannoxyl would appear to act by rendering the soil unfit for staphylococci to live and survive in. That is the condition met with more particularly in furunculosis. On the other hand, in the "mixed infection" of pulmonary tuberculosis the conditions of life for the staphylococci and associated microbes approach more and more aerobic conditions. At any rate, that would afford an explanation of the bacteriological findings recorded in Tables I. and II., where, although quantitative diminution in the amount of sputum occurred under the treatment, yet qualitatively the "mixed infection" remained more or less constant throughout. This is suggestive that the curative action of the stannoxyl may have been in attenuating the virulence of the microbes present.

How stannoxyl in the soil may bring about the attenuation of virulence is unknown; but certain experiments of Frouin as bearing on the question may be quoted. When metallic tin is incorporated in a nutritive medium containing alcohol, which is then inoculated with *Mycoderma aceti*, the production of acetic acid in the medium is diminished or totally hindered, although the growth of the microbe is not interfered with.[4] Also metallic vanadium or a salt of vanadium, when added to a nutritive medium inoculated

with *B. pyocyaneus*, favours the development of the microbe while hindering the production of pigment.[8] These experiments permit one to suppose that the attenuation of virulence is possibly due to some reaction akin to that which electrolytes play generally in activating and in inactivating enzymic activities.[9] The question is both an interesting and important one, opening up, as it does, new vistas of research.

I wish to express my thanks to Lieutenant-Colonel E. Carroll, I.M.S., Captain K. B. Clarke, R.A.M.C. (T.), Dr. James Miller, and Dr. S. Penny Snook for kindly placing the above patients at my disposal for the purpose of this investigation.

BLOOD-PRESSURE MEASUREMENTS:

USES AND LIMITATIONS IN MODERN MEDICINE.*

BY MAJOR EUGENE S. KILGORE,

MEDICAL OFFICERS' RESERVE CORPS, UNITED STATES ARMY, SAN FRANCISCO.

THIS review confines itself necessarily to a limited number of points in the broad field covered by the title—points which appear to be specially worth consideration by the practitioner because they are clinically valuable and insufficiently recognised or because they are widely talked about and over-rated.

Technic.

Blood-pressure technic has become fairly well standardised and its use practically universal. It is still well to insist, however, upon the necessity of using a cuff 12 cm. wide, a mercury column for pressure gauge or one of the spring instruments which is checked up from time to time against mercury, the securing of mental and muscular relaxation by the patient when measurements are taken, and the use of the simplest indices for locating systolic and diastolic reading points. The exact relation of clinical readings, both systolic and diastolic, to the true blood pressure is still a matter of academic interest and discussion, but the important thing clinically is very simple—merely the establishing of definite normal standards and the interpretation of figures within or without these limits accordingly. So long as our technic gives results with a fairly uniform relation to the true pressure clinical demands are met, and the test of a good index is its ability to give constant results.

Normal standards for systolic pressure have long been established according to the simple palpatory technic, and I fail to see justification for the recent tendency to resort to more complicated methods. The oscillatory method, still used with some of the graphic instruments like Erlanger's and with spring instruments like the Tycos and von Recklinghausen and by some even with mercury manometers, and still referred to by certain writers as the standard of accuracy, I have shown to be particularly untrustworthy in clinical work.[1] The auscultatory method, as shown by Berkley, Rowe, Stabler, and myself,[2] gives results most of the time which are just about as good as those of simple palpation; but not very infrequently there are cases in which the arterial sounds are far from clear, and occasionally those in which auscultatory readings are definitely lower than those made with the finger. Published recognition of this long-observed fact has recently appeared in an article by Taussig and Cook.[3] As shown in Fig. 1, auscultatory readings are usually higher by 5 to 15 mm. Hg than palpatory readings, and for this reason the feeling has gained ground that auscultatory readings are nearer the true blood pressure. As already indicated, however, it is not the absolute truth of the readings which is of clinical value but only definiteness and constancy in the relation of the readings to the true pressure; so that even if the supposition about increased absolute accuracy of the auscultatory readings were true, it would not mean that they are superior for clinical use. As a matter of fact, however, it is probable that the auscultatory readings are actually farther from the truth than the palpatory readings, since in the reported experiments in which palpatory readings were compared with actual intra-arterial pressure in human subjects the former were found to be too high ([4] [5]). For this reason, as well as for simplicity and convenience, the palpatory systolic method is prescribed for use by interns and students in the University of California Hospital.

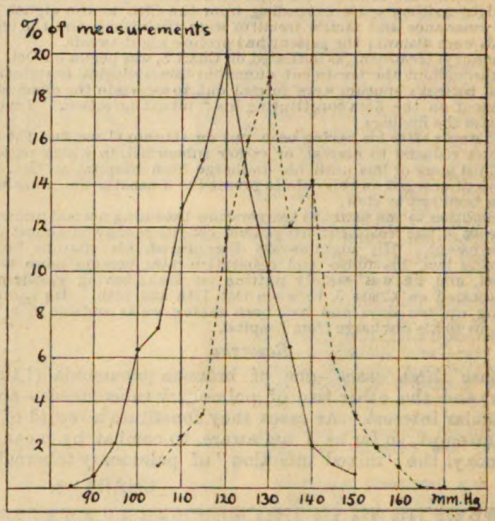

FIG. 1.—Systolic measurements of normal young men. Solid line shows result of 915 palpatory determinations on 314 individuals; dotted line 908 auscultatory measurements on 186 individuals. Recumbent position. Ages 16 to 36 years, mostly 17 to 19 years.

Diastolic readings are best made by the auscultatory method, the "change of sound," or fourth phase, being used when it is clearly marked, otherwise the disappearance of sounds. Which point most nearly corresponds to true diastolic pressure is still a matter of dispute, but is not of great clinical importance. Record is made of the criterion used, and in comparing cases it is understood that the change of sound represents a point usually 5 to 10 mm. of mercury higher in relation to the diastolic pressure than the disappearance of sounds.

Practical Applications.

The practical applications of blood-pressure measurements are few in comparison with the number and size of the volumes written on the subject. Certain associations are of the greatest importance, particularly that of high pressure with nephritis, pregnancy toxæmias, and acute cerebral pressure; and abnormally low pressure with Addison's disease.

Since myocarditis, cachexia, and other conditions responsible for low pressure are as a rule outspoken, a decidedly subnormal pressure is of great value in the diagnosis of Addison's disease. The lower limit of normal systolic pressure, however, as indicated in the books, is as a rule too high. Thus the lower limits of normal for young adults, according to Janeway, is 100, to Wiggers 100, to Norris 103, and to Goodman 120. Fig. 1 shows the results of systolic pressure measurements of healthy young adults taken during the course of medical examinations for admission to the State university. It is in substantial agreement with the results obtained by Lee[6] at Harvard University, and shows that while with the palpatory method the majority are within the commonly assigned limits of normal, a not inconsiderable number are below 100, and an occasional one as low as 85 or 90.

The upper limit of normal systolic pressure also needs a little more elasticity than is usually given to it in the books, especially if the auscultatory method is used. Fig. 1 shows that in a considerable proportion of healthy young men under the conditions of a first examination, at least, the auscultatory systolic pressure is above 140 and occasionally considerably higher. By the palpatory method only 2 per cent. are as high as 145 to 150. It should be stated that the men who showed these high figures were followed until we

* From the Department of Medicine and the Students' Infirmary, University of California.

were satisfied that they were normal; and the extreme figures shown in Fig. 1 would not appear if first measurements were excluded.

Even after ruling out high figures due to excitement, &c., the diagnostic significance of hypertension is frequently in doubt between nephritis, arterio-sclerosis, and so-called "idiopathic hypertension." The diagnosis "idiopathic hypertension" or "hyperpiesis" will have at times to be made; but if the pressure is sustained at a high level—180 mm. of mercury and over—the chances are great that kidney lesions are present. Almost all autopsies of individuals who have carried habitually a pressure of 200 mm. Hg or over show renal changes (Lee[7]), though at times it is problematic how far these changes are chargeable as causes. Many are undoubtedly minor incidents in widespread arterial disease. The importance of blood pressure to the obstetrician and the brain surgeon is well recognised and need not be discussed here.

The peculiar increase of leg over arm[8] systolic measurements when the patient is horizontal and the increase in pulse pressure are at times of considerable value as confirmatory evidence in the diagnosis of doubtful cases of aortic insufficiency. They are also useful in estimating the extent of aortic valve damage.

A valuable and little known[9] use of the blood-pressure apparatus is found in the recognition of pulsus alternans, which for prognosis is the most important and, at the same time, the most easily overlooked form of cardiac irregularity. In such cases, at times even those difficult to recognise by other means, it is simple to adjust the cuff pressure between that of the large beats and the alternate smaller ones, so that only every other pulse sound is heard.

In these instances blood-pressure determinations are of great positive value in clinical medicine, playing as they do an essential part in diagnosis, and also helping in prognosis and treatment. Their value is tremendously enhanced by the fact that in the earlier stages of arterial and renal disease hypertension is often the only sign of trouble. And when to this is added the extreme simplicity and definiteness in making the observations as contrasted with the uncertainty of blood-pressure guesses from feeling the pulse, the importance of the sphygmomanometer is seen to be very great.

A sharp distinction should be drawn, however, between the few conditions already mentioned and the many others in which blood pressure is of distinctly minor or negligible importance, notwithstanding the amount of writing on the subject. Many facts have been contributed concerning blood pressure in a large number of conditions—tuberculosis and many other fevers, ductless gland disorders, nervous and mental diseases; blood-pressure in high altitudes, in the tropics, in various races, &c.; but while many of these researches have academic interest, little of positive clinical value has come from them. Blood-pressure findings which have been supposed to be characteristic of this or that disease have too many exceptions or tend to show the characteristic changes only in the advanced cases when other clinical features are distinctive.

Blood Pressure in Functional Diagnosis.

The hopes that blood pressure would be a reliable functional index, and therefore a guide in the treatment of febrile and other circulatory disorders, have mostly met with disappointment. And the disappointment might have been predicted if the significance of blood pressure had been more clearly recognised. The rate of blood flow, the number of cubic centimetres per minute passing through the capillary system, is the thing which determines the efficiency of the circulation, and this may undergo extensive changes without any corresponding alteration of pressure, at least of systolic pressure. The reason for this is that one of the factors (increased heart output) making for increased rate of flow also elevates the pressure, while the other (vasodilatation) tends to lower pressure. So that, while it is often true that heart failure is accompanied by a reduction of blood pressure from a previously normal or elevated level, it also frequently happens that, together with a weak heart contraction and small output, there is enough peripheral obstruction to keep the pressure high. It is not unusual even to see moderately high pressure, when a patient enters the hospital with cardiac decompensation, changed to normal pressure with improvement of the circulation.

In fevers, particularly typhoid fever and pneumonia, little practical value has resulted from the many efforts to interpret the condition of the circulation from blood-pressure readings. For several years at the University Hospital we have undertaken a continuous study of these cases, systolic and diastolic-pressure readings being made every four hours, the same as the pulse and temperature records, but so far it is not possible to say that these pressure determinations have proved of much value in the conduct of the cases. Gibson's rule[10] in the prognosis of pneumonia has attracted much attention, and several investigators have confirmed Gibson's statement that "a pressure appreciably below the normal in pneumonia is invariably of evil omen, and any considerable fall bodes disaster. When the arterial pressure, expressed in mm. Hg, does not fall below the pulse rate expressed in beats per minute, the fact may be taken as of excellent augury, while the converse is equally true." Our experience, however, is that, while Gibson's rule may be true in many desperate cases, where the prognosis would be very guarded anyway, in the more doubtful cases it is of no particular value, as the unfavourable picture, according to Gibson, will not develop until an hour or so before death. Newburgh and Minot[11] recently have come to similar conclusions.

Diastolic Pressure.

My remarks so far have related mainly to systolic pressure. Increasing interest in the last few years has been taken in diastolic and pulse pressures. Some have thought diastolic pressure a better index than systolic pressure of what is normal or abnormal, for the reason that it is nearer the mean pressure and in a given case is usually more stable and less affected by excitement or other accidental disturbing influences. To my mind, however, this advantage, if it be such, is offset by the greater uncertainty which we[2] have found to be connected with the diastolic readings. Moreover, after a considerable number of researches on the subject there is still lack of agreement as to which auscultatory phenomenon indicates diastolic pressure, the change from a loud to a dull tone or the final disappearance of arterial sounds. In most of these studies the standard for comparison was the oscillatory method, which, as already indicated, is highly unreliable itself. The two criteria, though usually 5 to 10 mm. apart, have no constant relation, and may differ by a large amount or by practically nothing.[2] And if one attempts to confine himself to either index, many cases will be encountered in which it is anything but clear cut.

These facts argue rather strongly for retaining systolic pressure, with its long-established normal standards, as the most important blood-pressure determination. The diastolic

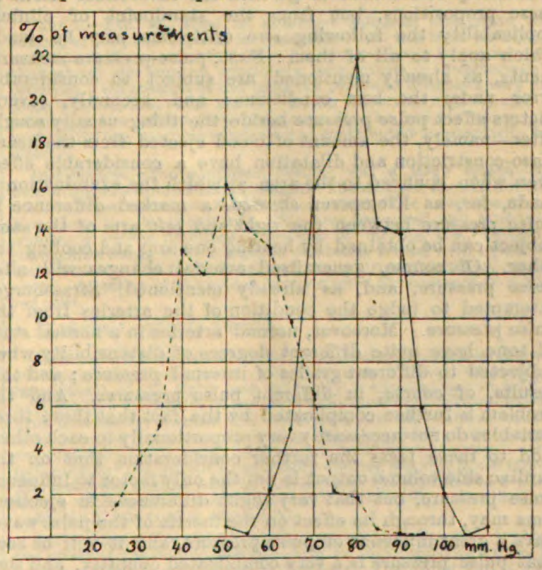

FIG. 2.—Diastolic and pulse pressure measurements of normal young men. Solid line shows results of 542 diastolic determinations (change of sound criterion) on 183 individuals; dotted line 720 measurements of pulse pressure on 177 individuals (difference between auscultatory systolic readings and "change of sound" diastolic readings). Recumbent position. Ages 16 to 36 years, mostly 17 to 19 years.

pressure as found in a series of normal young men entering college is shown in Fig. 2. It will be seen that the absolute range of variation among these measurements is practically

as great as among the systolic measurements shown in Fig. 1, so that relatively the dispersion among the diastolic measurements is greater.

Pulse Pressure.

The same considerations naturally speak for conservatism in the use of pulse pressure; for, being the difference between systolic and diastolic pressures, its error is a composite of the errors from both of these readings. So that before making any attempt to interpret pulse pressure, in the absence of a large series of concordant readings, we should discount deviations probably up to at least 10 or 15 mm. of mercury.

But even after liberal allowances for observational errors the field is by no means clear for making pulse pressure the basis for unrestricted deductions about the behaviour of the circulatory organs. The temptation to use pulse pressure in this way is natural enough and has often been yielded to. Indeed, on theoretic grounds such attempts are quite justifiable. Thus, many years ago Strassburger[12] claimed that the quotient of pulse pressure divided by systolic pressure was of value in showing the part played by cardiac work and also vascular resistance. According to him, if the quotient remains unchanged increase in systolic pressure means increased heart work, and vice versa; while increase in systolic pressure with an approximately equal fall in the quotient means increased vaso-motor tonus. In a similar way Fuerst and Soetbeer[12] suggest the use of a modified Strassburger formula, viz.:—

$$\frac{\text{pulse pressure}}{\text{diastolic pressure} + 1/3 \text{ pulse pressure}}.$$

In 1904 Erlanger and Hooker,[13] and in 1906 von Recklinghausen,[14] proposed the product of pulse pressure multiplied by pulse rate as an index of the rate of blood flow, and hence of heart activity. Three years ago Barach[15] suggested the use of a so-called "energy index" to indicate the expense of cardio-vascular energy. He multiplies the pulse rate by the systolic pressure and by the diastolic pressure, and adds the products to obtain the index (S.D.R. index). Stone[16] excited considerable interest in this country by proposing to use the quotient of pulse pressure divided by diastolic pressure as an index of so-called "heart load." Later he modified his claims for this formula.[17]

It is impossible here to go into the theoretical merits of these propositions, but from the standpoint of clinical applicability the following two criticisms may be made which apply to all of them: First, pulse-pressure measurements, as already mentioned, are subject to considerable error under the best conditions; and, secondly, several factors affect pulse pressure beside the thing usually sought after—namely, the amount of blood ejected from the heart. Vaso-constriction and dilatation have a considerable effect even when confined to the area at which the examination is made, for, as Klemperer showed, a marked difference in pulse pressure between the right and left arm of the same subject can be obtained by heating one arm and cooling the other. Of course, generalised arterial changes will alter pulse pressure, and, as already mentioned, Strassburger attempted to judge the condition of the arteries from the pulse pressure. Moreover, normal arteries in a normal state of tone have quite different degrees of distensibility when subjected to different grades of internal pressure; and this results, of course, in different pulse pressures. And the problem is further complicated by the fact that these three variables do not necessarily vary proportionally to each other. Add to these facts the further consideration that on the cardiac side volume output is not the only factor to influence pulse pressure, but that very slight differences in ejection-time may, through its effect on the inertia of the pulse wave, have a great influence on pulse pressure, and it will be seen that pulse pressure is a very complicated quantity, and that its exact interpretation would be difficult even if its determination were a matter of great accuracy. Fig. 2 shows the wide range of pulse pressures obtained in the examination of healthy young men. In Fig. 3 is shown the distribution of the same measurements after each pulse pressure is divided by the corresponding diastolic pressure—i.e., this figure represents the variations among normals of "heart load" according to Stone's formula. The dispersion is still great. The various other relations of pulse pressure to systolic and diastolic pressures have not been worked out in these cases; but it is evident that any set of ratios constructed from these figures would show great variation.

It appears justifiable, therefore, to regard with scepticism any formula which proposes in terms of any moderate alterations of pulse pressure to classify clinical cases as normal or abnormal. And even in following the progress in a given case, as, for example, a case of internal concealed hæmorrhage (Wiggers[18]), much caution must be exercised.

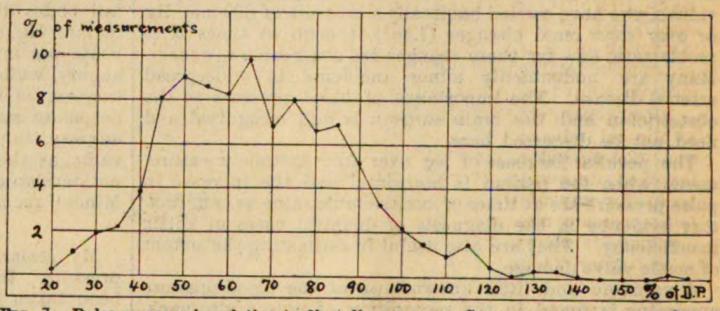

FIG. 3.—Pulse pressure in relation to diastolic pressure. Same measurements as shown in Fig. 2, but here in each case the pulse pressure is expressed as a percentage of the corresponding diastolic determination (change of sound).

Another attempt to gauge heart efficiency with the blood-pressure apparatus was the method described in 1910 by Goodman and Howell.[19] With falling cuff pressure the so-called "tone phases" were auscultated below the cuff, and the second and third phases (the murmur and the following clear sound) were considered to be related to heart strength, and the first and fourth phases to heart weakness. Normally they considered that the sum of second and third phases should be about 75 per cent. of the total pulse pressure. Fig. 4 shows large variations above and below this amount obtained in observations on normal young men.

In addition to these attempts to utilise blood-pressure readings in functional diagnosis several functional heart tests have been proposed which involve, among other observations, measurements of blood-pressure responses to exercise or other manœuvres. It is impossible here to discuss these tests further than to suggest that their failure to come into more general use will probably be found to be due to the fact

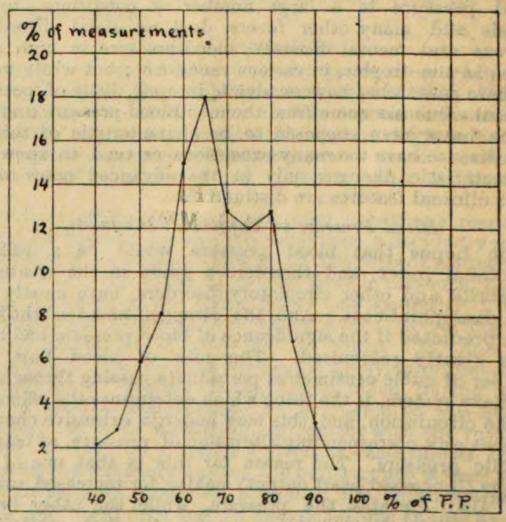

FIG. 4.—"Tone phases." In each case the sum of second and third auscultatory "tone phases" is divided by the pulse pressure, and these quotients are charted as percentages of the pulse pressure. Based on 221 observations on 104 normal young men from 16 to 36 years of age. Subjects recumbent.

that the responses of normal subjects vary considerably and overlap the results which are supposed to indicate heart weakness. And it is doubtful if such tests of the circulation will ever compare in value with a careful history and physical examination, including due consideration of the patient's own sensations after exercise.

Summary.

Experience has shown great practical clinical value of blood-pressure measurements in connexion with a limited number of conditions—namely, arterial and renal diseases, cerebral pressure, pregnancy toxæmias, Addison's disease, and, to less extent, aortic insufficiency. Before attributing pathological significance to the measurements, however, wider normal limits (both systolic and diastolic) should be recognised than those generally indicated in the books. Figures from normal young adults are presented in substantiation of this statement. An important and little-known application of the blood-pressure apparatus is its use in the detection of pulsus alternans. It is urged that systolic pressure be retained as the most important measurement, and that the simple palpatory technic be used.

Blood-pressure determinations in general have fallen short as clinical indicators of circulatory function. Pulse pressure, and consequently the various formulas in which it is involved, depends upon too many factors to be a very useful index for any of them. Great variation is shown among pulse-pressure measurements of normal persons. The same criticism is shown to be applicable in the case of the auscultatory "tone phases."

FIVE CASES OF RAPID DECEASE IN YOUNG MEN.

BY ADOLPHE ABRAHAMS, M.D. CANTAB., M.R.C.P. LOND.,

MAJOR, R.A.M.C.; OFFICER-IN-CHARGE MEDICAL DIVISION, CONNAUGHT HOSPITAL, ALDERSHOT;

AND

N. F. HALLOWS, M.D. OXON., D.P.H.,

PATHOLOGIST, CONNAUGHT HOSPITAL, ALDERSHOT.

THE five cases described below appear of sufficient interest to publish, partly because of the clinical and pathological details which they individually supply, and partly because of certain accidental features which, notwithstanding essential differences, justify their collection in a group. Their occurrence in comparatively young men in rapid succession—they were admitted to the Connaught Hospital, Aldershot, within one week—is also of interest.

CASE 1.—Pte. F. R., aged 26, was admitted as a case of bronchitis on account of "dyspnœa." No history was forthcoming save that he was said to have been ill for several days. Interrogation was impossible owing to the patient's extreme deafness; he was a sufferer from chronic otitis media. The "dyspnœa" in question was soon recognised to be air hunger, and a provisional diagnosis of uræmia was made, partly upon this feature and partly upon the condition of a heart clearly hypertrophied to the left without showing cardiac disease of any kind. No urine was obtained. The blood pressure was not taken. The patient suddenly and unexpectedly collapsed and died within two hours of admission.

Post-mortem.—The kidneys exhibited very little renal substance and were obviously in a state of chronic interstitial nephritis, the weight of the pair being 4¾ oz. The heart weighed 18½ oz., and except for great hypertrophy of the left ventricle was normal.

No history of antecedent renal disease was ever obtainable, but the presence of a chronic otitis media suggested the possibility of scarlet fever in childhood.

CASE 2.—Pte. S., aged 30, was admitted the following day, very livid and in a condition of extreme respiratory distress. The dyspnœa being identified as "air hunger" by the medical officer who had been in charge of the previous case, a diagnosis of uræmia was made (with precocious confidence), more especially as the left ventricle was much hypertrophied and the maximum systolic blood pressure was 180 mm. Again no urine was forthcoming, and the patient was far too exhausted to give the history of this or any previous illness. It was, however, noted that the temperature was 103° and that a distinct cardiac diastolic murmur was present. Owing to the patient's intense distress careful examination was impossible. Venesection was at once performed. Death occurred just 35 minutes after admission.

Post-mortem.—The kidneys were found healthy in size and structure. The heart was much hypertrophied, especially the left ventricle; weight 18 oz. The free edges of the aortic cusps were greatly thickened but not ulcerated; the mitral valve showed an extreme degree of button-hole stenosis. The lungs exhibited an early stage of red hepatisation.

This pair of cases seem to us to be an excellent example of two familiar fallacies. The first is the traditional expectation of encountering a second example of some relatively rare condition very shortly after one has appeared. The second is that of diagnosing a case on a general superficial resemblance to something one has recently seen. No amount of persuasion to the contrary will destroy the inclination to rely on a supposed tendency of rarities to run in couples and trios; and although teachers of medicine are perpetually pointing out the folly embodied in the second fallacy, no amount of experience appears to render one immune thereto.

CASE 3.—Pte. K., a German prisoner, aged 32, admitted intensely cyanosed and dyspnœic. T. 104°. There was a history of a recent illness of a few days' duration. Very few signs were present in the chest. Venesection was performed. Death occurred within 12 hours of admission.

Post-mortem.—The lungs showed acute general bronchitis and congestion. The other viscera were congested, but exhibited no obvious morbid change, save that scattered areas of early necrosis in the liver were visible. A pure culture of a streptococcus was obtained from the lung; culture from the spleen was negative.

Death in this case appeared to be due to a primary streptococcal toxæmia or septicæmia.

CASE 4.—Pte. M., aged 29, admitted collapsed and pallid with a history of frequent copious hæmatemeses. At the time no history of antecedent illness was obtainable, but subsequently it was ascertained that about six months previously hæmoptysis (? hæmatemesis) had occurred. On account of the patient's profound collapse a very incomplete examination was made. Death occurred eight hours after admission, the patient developing coma for the last six hours. In all probability the morphia administered contributed substantially to this state.

Post-mortem.—The dominant feature was a large spleen—30 oz., exhibiting subcapsular hæmorrhages. The stomach showed submucous hæmorrhages, mainly on the lesser curvature. The intestines contained blood from the ileum onwards. The liver was small and studded with numerous yellow umbilicated nodules of varying size. These were shown afterwards to be composed of fibrous tissue, with a peri-lobular distribution. The blood (examined post mortem) contained no myelocytes. A section of the spleen demonstrated the presence of nucleated red cells.

Diagnosis, splenic anæmia.

CASE 5.—Corporal H., admitted as influenza among a large number of apparently similar cases. Routine examination discovered great impairment of the right base, evidently due to presence of fluid. On exploration a syringeful of perfectly clear *colourless* fluid was extracted. This peculiarity, coupled with the feature that the patient was a New Zealander, led to an immediate diagnosis of hydatid of the lung. On examination of this fluid, however, no hooklets were found. On the following day the patient's respiratory distress was very much increased. The heart was pushed over to the left and the presence of a pneumothorax with most typical signs was unmistakable. Death occurred suddenly 24 hours after admission.

Post-mortem.—The right lung was found to be collapsed. On incision the whole of the middle lobe was seen to be occupied by a cyst, which on removal left a cavity 7 cm. in diameter. The lining wall of the cyst was extracted intact without difficulty. The cyst had pointed on the anterior surface, where pulmonary tissue was represented by nothing more than the external wall of the cyst. There was no evidence of daughter cysts. The lining membrane on incision was found to be a uniocular cyst containing some slightly stained turbid fluid. The wall was everywhere covered with granular bodies, shown microscopically to be scolices of *Tænia echinococcus*, both invaginated and extruded. The liver was carefully examined, but there was no evidence of other cysts either in this viscus or elsewhere.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF HYPOADRENIA SIMULATING INTESTINAL OBSTRUCTION.

BY H. M. RASHBROOK, M.B., B.S. LOND.,
MAJOR, R.A.M.C. (T.C.);
AND
F. W. CARTER, M.B., CH.B. ABERD.

THE difficulties of diagnosis of adrenal disease without the characteristic Addisonian syndrome are well recognised, and a typical case having come under our care it has been thought worth while to record it.

A soldier, aged 19, first came under the care of one of us in August, 1915, with a typical attack of acute appendicitis; appendix with gangrenous tip removed; uninterrupted recovery. Patient was re-admitted to hospital on Nov. 29th, 1917, and stated that on rejoining his unit after his last illness he had an attack of faintness on a march and was again in hospital for six weeks. Since then he had been subject to periodic attacks of abdominal pain and vomiting, accompanied by constipation. Pain usually was in epigastric region; occasionally radiated into right iliac fossa. The attacks had necessitated his being invalided from the service.

His illness when seen for the second time had started seven hours previously. On admission pale and collapsed; epigastric pain. Vomiting was present, at first bilious, later developing a somewhat fæcal odour. Constipation extending over previous day or two was also admitted by patient. T. 95° F., P. 110. Palpation of abdomen elicited tenderness in epigastrium and in right iliac fossa radiating from old operation scar downwards and inwards. A provisional diagnosis of intestinal obstruction due to adhesions from former attack of appendicitis was made.

The collapse was treated by rest, warmth, and stimulants. An enema gave a good though constipated result, and the general condition greatly improved. Vomiting ceased, though local pain and tenderness remained. The pulse also became less rapid and stronger, but still did not become quite normal in force.

In a day or two patient felt quite well except for feeling of fatigue on exertion. He was allowed up for a little each day and seemed to suffer no inconvenience, but retained to some extent a pinched and cold appearance. The bowels were kept moved regularly by administration of liquid paraffin each evening. Beyond slight diminution of percussion note and few fine crepitations at apices of lungs in front a general physical examination revealed no signs of organic disease. Examination of sputum for tubercle bacillus negative.

On Dec. 6th, another attack of abdominal pain with repetition of previous vomiting occurred. At this time it was noticed that deep palpation over abdominal scar produced a feeling of nausea. Same treatment as during previous attack; recovery equally rapid and marked. It was then decided to explore the abdomen, but it was not until the end of December, when the general condition had improved, that this procedure was considered advisable.

On Jan. 5th, two days before date of proposed operation, a third attack developed. The abdominal pain recurred; vomiting not so prominent as previously. Marked syncopal symptoms with great dilatation of pupils were also present. Patient's general condition became worse; death occurred same evening.

On account of our inability to understand the sudden termination of the case, permission was obtained for a partial post-mortem examination.

The abnormal findings in a routine examination of the abdominal and thoracic viscera were as follows:—

Pleura.—A few fibrous adhesions at right apex. *Lungs.*—In right apex a small fibro-caseous patch with some calcification about size of two-shilling piece. *Heart.*—Free margin of mitral valve showed fringe of organised granulations; valve appeared healthy.

Stomach.—Somewhat dilated; musculature thinned. *Large intestine.*—Few adhesions between lower end of cæcum and parietal peritoneum; not such as could cause any obstruction. A small healed dimple marked site of appendix. *Mesentery.*—Glands throughout palpable.

Kidneys and suprarenals.—Considerable fibrosis of perirenal structures, particularly in upper part; careful dissection was necessary to separate suprarenals from surrounding tissues. The adrenals were not altered in shape or increased in size. On section both were found to be the seat of caseous degeneration with a few scattered calcareous particles.

The mesenteric glands and adrenals were sectioned. Microscopic examination of glands showed only small round-celled infiltration. Sections of suprarenal bodies showed that for the most part the glandular cells had been replaced by degenerated caseous masses, but outside these giant-cell systems could be clearly distinguished. In a few places the cells composing cortex of glands could still be defined, but even these for the most part showed cloudy swelling and irregular staining.

Langlois, Gourfein, and others have demonstrated by animal experiments that ten-elevenths of the suprarenal bodies can be destroyed without the general body metabolism being so disorganised as to cause death. In the case here noted the adrenal destruction seems to have reached a very considerable degree before the final issue occurred. Lewin points out from an analysis of published cases that in 28 per cent. no pigmentation occurred. At the present time the exact cause of the pigmentary changes in Addison's disease does not seem to have been ascertained with any degree of certainty. In this case we suggest that it may possibly be due to the fact that not sufficient time elapsed between onset of disease and patient's death to allow it to occur.

Ebstein and Zaudy have recorded the occurrence of cases of suprarenal disease with predominant abdominal symptoms, but we have not be able to ascertain the frequency with which they occur. Owing to the previous abdominal history and the symptoms of partial obstruction which responded to the usual methods of treatment the probabilities seemed to point to the clinical diagnosis made. It was not until the post-mortem examination revealed disease of the suprarenal capsules that the symptoms here recorded were viewed in their proper perspective and recognised as another clinical entity—namely, hypoadrenia.

A DEVICE FOR PREVENTION AND TREATMENT OF ADENOIDS.

BY ISABEL ORMISTON, M.B.,
MEDICAL INSPECTOR OF SCHOOLS, TASMANIA.

WHEN in 1914 a non-operative method of treating adenoids, discovered by Mrs. E. Handcock, was brought under my notice, I was not merely sceptical, but openly scoffed at the idea. I was bound to admit, however, that after two years' residence in a children's hospital and three years' medical inspection of school children I was not satisfied with the results of the usual operative treatment; as such a large percentage of cases remained mouth-breathers and continued to suffer from nasal catarrh. In many cases also the growth returned.

Description of Method.

This new treatment consists in the production of a sneeze by lightly touching the nasal septum near the tip of the nose with a slightly irritant adhesive powder, made from powdered iris root and soap. The powder is not sniffed up into the nose.

The effect of the sneeze is to expel the catarrh or muco-pus from the nose and the adjacent sinuses. This stimulation should be repeated till a "dry" sneeze results. The free flow of lymph which accompanies the sneeze acts as a most efficient washout, and no doubt acts, too, as a natural protective fluid against the bacterial invasion present in adenoids.

The children who are old enough to blow their noses are then taught a handkerchief drill. They stand in line, and at the word of command they grasp the bridge of the nose and raise the elbow to the height of the shoulder, and then blow forcibly. The position of the elbow automatically expands the lungs and ensures a strong current of air being forced through the nose, which is held at the bridge to prevent pinching of the nostrils.

Results.

Under the supervision of Dr. Octavia Lewin an experimental clinic of this nature has been in existence for six months at the Roll of Honour Hospital for Children, Harrow-road. The committee is so satisfied with the results that it is to be continued as part of the hospital routine.

I have been observing this simple method of treatment for the past four years and have found the results most gratifying. The first marked improvement is curiously enough in the digestive system. The dyspepsia and constipation, which are so common an accompaniment of adenoids, are the first symptoms to disappear. Perhaps some student of reflex action could explain this. We know that the nose is an early indicator of indigestion, alcoholism, and gout; so perhaps it is not surprising if the digestive system can be reflexly affected by a nasal stimulus.

Deafness due to the blocking of the Eustachian tube also disappears quickly.

The time taken for the shrinkage of the growth varies. Generally speaking, the younger the child the quicker the results. A great deal depends on the intelligence of the mother, as the treatment must be carried out every day. In older children and adults with nasal obstruction a certain amount of manipulation of the head and neck is necessary to stimulate the lymphatic circulation.

One of the chief advantages of this form of treatment is that large numbers of school children should be treated simultaneously at little cost. School nurses could be quickly trained to carry out the treatment under the supervision of the medical inspectors of schools. At the present, when, owing to the shortage of staff, the out-patients' departments of the various hospitals find it impossible to cope with the number of cases from the board schools, it seems the ideal moment to introduce the system into our schools.

A clinic has lately been started at the Westminster Health Association, Greek-street, Soho, where the enthusiasm of the mothers over the improvement in their children is most encouraging.

Illustrative Cases.

The following are notes referring to a few of the cases treated:—

CASE 1.—Male aged 3½. Seen April, 1913. Difficulty in breathing; slept with mouth open; slightly deaf; one eye squinted slightly; frequently constipated; distended abdomen. Out-patient for two years at Royal Free Hospital and afterwards at Great Ormond-street. In April was taken to Central London Nose, Throat, and Ear Hospital, where operation for adenoids was advised. He was then treated by the above method for three months, and treatment was kept up for another three months by the mother at home. In August, 1913, the father wrote as follows: "Our boy is in splendid health. Eyes are straight; deafness gone. Sleeps well with closed mouth, and has grown considerably in height and increased in weight."

CASE 2.—Male aged 10. Suffering from asthma and adenoids. This boy was in such a generally weakened state that the medical man under whom he was placed for the treatment of asthma advised his mother to try the Handcock treatment for adenoids before resorting to operation. Was treated from June 18th to July 27th, having as a rule three treatments each week, which were afterwards carried on by his mother at home. In November the mother wrote as follows: "I feel sure it will interest you to know that I took M—— the other day to see the doctor who had examined him before, and found adenoids and advised operation. He was delighted with his improved appearance, and said the adenoids had totally disappeared, and that he was better and stronger in every way."

CASE 3.—Male aged 42. Passed on to me by oculist. Complained chiefly of headaches, which lasted from 8 to 12 hours daily. The condition had existed 15 years and was not relieved by spectacles. On examination patient found to have nasal obstruction due to a deflected septum and thickened mucous membrane. He also had a calcareous ridge round the occipital region and calcareous nodules in tissues of back of neck. These were broken up by manipulation and patient made to sneeze daily. At the end of a fortnight he had two days' complete freedom from headaches. The treatment was continued for another three weeks, during which time he rarely had a headache which lasted more than an hour. I then gave patient instructions how to carry on the treatment and have not heard from him since.

Reviews and Notices of Books.

Diseases of the Nervous System: A Text-book of Neurology and Psychiatry. By SMITH ELY JELLIFFE, M.D., Ph.D., Adjunct Professor of Diseases of the Mind and Nervous System, New York Post-graduate Medical School and Hospital; and WILLIAM A. WHITE, M.D., Professor of Nervous and Mental Diseases, Georgetown University, &c. Second edition, revised, rewritten and enlarged, with 424 engravings and 11 plates. Philadelphia and New York: Lea and Febiger. 1918. Pp. 938. Price $7.00.

APART from the larger and more ambitious systems and encyclopædias of neurology, this is one of the first text-books of one volume, we believe, to embrace the whole of neurology from diseases of the sympathetic system to insanity. The authors are surely justified in their contention that all mental disease is nervous disease and that the distinction between the two is artificial. Further, they have in downright fashion refused to admit the claims of certain internists to filch from neurology the diseases of the ductless glands, maintaining rather that the "endocrinopathies" are but a part of vegetative or visceral neurology, as indeed they are. The scheme of this stimulating volume accordingly follows a division of the nervous system into three levels of functional activity, the vegetative, the sensorimotor, and the psychic.

The first is a study in itself, of ever-widening importance; within its limits is found an immense variety of disturbances of visceral mechanisms as yet far from being adequately differentiated into recognisable syndromes. Impairment of function of glandular, gastro-intestinal, genito-urinary, vascular, respiratory, cutaneous, bony, and other systems on their nervous side has been sadly neglected as a subject of clinical study, but a glance at the hundred pages allotted to this in the text-book will serve to demonstrate the richness of the symptomatology that is growing up round these topics and at the same time reveal the serious gaps in our present knowledge. We notice that the authors place the muscular dystrophies or myopathies under the endocrinopathies, in our view, somewhat prematurely; even where there is more justification, as, for instance, in the case of myasthenia gravis and possibly myotonia congenita, the origin of the disease in a defect of endocrine glands cannot be said to be clearly established.

Sensorimotor neurology, the ordinary organic neurology of the schools, is, of course, much better systematised and more thoroughly investigated. The authors have succeeded in compressing a remarkable amount of information into the 450 pages of this section, and, on the whole, the material is well apportioned. The relative meagreness of certain paragraphs may, no doubt, be set down to the desirability of conciseness. More attention, we think rightly, has been given to the exposition of group syndromes than to particularities of individual diseases, a method which avoids much overlapping.

As for the third section, the "psychical or symbolic systems," comprising some 200 pages, it is also remarkably complete within its limits. The authors are frankly Freudian in their outlook, attributing neurasthenia, e.g., "in most instances," to "excessive masturbation or frequent pollutions"—a point of view which has little to commend it, and appears to us unworthy of the critical spirit the authors elsewhere evince. This slavish following of a "master" does not appeal to English neurology.

The volume is nothing if not up to date. All the newest work in neurology and psychiatry is at least touched on, and the student will find paragraphs on dystonia musculorum deformans, dyssynergia cerebellaris progressiva, apraxia, cyclothymia, Alzheimer's disease, and so on, which are not to be found in many other text-books. The illustrations are many and valuable, especially the diagrams. In this connexion the authors appear to have borrowed far more illustrations than are original; in fact, they seem to have been able to obtain from other sources the pick of neurological drawings. The charts that are the conspicuous feature of Dejerine's "Semiology" are all here also. The printing is clear and the index is good. As a compendium of our knowledge in neurology and psychiatry the book is unusually satisfactory and reflects credit on the industry and wide reading and research of its compilers.

Locomotor Ataxia: An Introduction to the Study and Treatment of Nervous Diseases. By WILLIAM J. M. A. MALONEY, M.D. Edin., Neurologist to the Central and Neurological Hospital, New York, &c. Illustrated. London and New York: D. Appleton and Co. 1918. Pp. 299. Price 15*s.* net.

THE avowed plan of this book is somewhat out of the common. Tabes dorsalis is taken as the "text," so to speak, from which to give an exposition of a great deal of clinical anatomy and physiology which may be subsequently applied to other diseases of the nervous system. Thus there are long chapters on disturbances of reflex motor function, sensory function, attitude and movement, of the vegetative nervous system—all as exemplified by tabes, and no doubt of value to the student. The book in its first part really constitutes a kind of introduction to the study of the nervous system, and as such is worthy of note.

The second part is devoted to an elaborate description of the treatment of tabes and of its symptoms, mainly ataxia, by the author's methods, which are modified from, and it may be an improvement on, those of Frenkel, of Heiden. In a word, the keynote of the method is the removal of competing visual images by blindfolding the ataxic patient, thereby ensuring his dependence on such postural images as he retains and facilitating their re-establishment. Apparently the author has had encouraging results.

Where there is so much attention given to the minutiæ of one disease we should have liked to see an attempt to explain the mechanism of the Argyll Robertson pupil. No reference is made to the experimental work of Karplus and Economo in this connexion. Among the visceral crises nasal and uterine varieties are not given a place. Gowers's work

on the auditory atrophy of tabes is omitted. The expectation of life of the tabetic is given as "at least two-thirds that of the average healthy man." Marie and Mocquot have shown that it is even higher than that. There are a fair bibliography and a number of good illustrations.

Diseases of Occupation and Vocational Hygiene. Edited by GEORGE M. KOBER, M.D., LL.D., and WILLIAM C. HANSON. London: Wm. Heinemann (Medical Books), Limited. 1918. Price 32*s.* net.

THE present war has brought home to nations as never before their dependence upon industry to supply them with material for offence and defence, and just now, when in this country the profession is looking forward to a Ministry of Health, attention is being specially directed to the effect of industrial occupation upon health and upon the production of disease. A new branch of preventive medicine is rapidly coming into being, a branch concerned with the environment of the workshop in contrast to the public health of the past concerned with the environment of the home. Development on these lines is needed to meet the altered conditions of the working classes; it is needed, and indeed is overdue, for industrial medicine has not kept pace with the advance in industry which took place in the last century. Those who recognise the need are looking for some standard source of information containing knowledge on the subject as it stands to-day, and the publication from America of the volume under review is opportune. Probably there will be few examining its contents who will not be astounded at the size of this new field of medical science, astounded at the advances made, astounded that they have practised among an industrial population in entire ignorance of it all. The day is past when a doctor can be content to treat his patients, the majority of whom are industrially employed, with no knowledge of how they spend their lives or of the influences injurious to health to which they are daily exposed. Industry and industrial processes are ever altering and expanding without consideration for the health of the workers. The living organism reacts to these influences in new and unexpected ways, which may even be associated with injury to limb and danger to life. "At hercule homini plurima ex homine sunt mala." The practitioner of the future must acquaint himself with what goes on within the factories in his district as well as within the homes.

This volume is undoubtedly of great value and will remain as a book of reference; but the editors set themselves a hard task by seeking contributions from among authorities living in different countries. Each author appears to be a law unto himself unchecked by the editors; considerable overlapping has occurred; divergence of opinion may be detected, and omissions are noticeable. Such matters, however, may be rectified in a subsequent edition and may only be taken as indications of the rapid increase of knowledge on the subjects discussed. Although English writers contribute we note that no reference is made to the following: Professor A. E. Boycott's work on ankylostomiasis among Cornish miners; the report of the Home Office Committee on the use of lead compounds in the painting of buildings; the report of the Royal Commission on Metalliferous Mines and Quarries (with its important conclusions on fibroid phthisis, which have justified the Act just passed giving compensation for silicosis of the lungs); the report of the Home Office Pottery Committee (the basis of the splendid code of regulations now controlling that industry); the work of H. C. Ross on pitch cancer; the report of the Compensation Committee on Dupuytren's contraction; Prosser White's book on Occupational Dermatitis.

Probably, although this book was only published this year, it was too late to contain more than a passing reference to the recent work put out by the Health of Munition Workers Committee. This is especially unfortunate, as the section devoted to industrial fatigue is somewhat inadequate to the importance of the subject. The food question also and the industrial canteen have received more attention in this country recently (particularly from Major Greenwood and Leonard Hill) than is indicated. The same reason may account for the omission of the whole question of toxic jaundice and aplastic anæmia due to tetrachlorethane and the nitro-derivatives of benzine—e.g., T.N.T., which has been so carefully worked out in England.

A general criticism may be made that the space devoted to descriptions of processes and industries is too great for those ignorant of the trades to whom descriptions without personal inspection are of little value and too small to be useful to those already acquainted with them. This fault is, however, one common to most treatises on occupational hygiene. The editors have aimed high, and if their aspirations have not been entirely fulfilled, nevertheless they are to be congratulated in getting together much useful knowledge on a subject of rapidly increasing interest and importance, and they should be rewarded by an early call for a second edition. Should this happily occur, the suggestion is worth making that the volume should be divided into two separate works—one dealing with the hygiene of industry and the means which it affords for healthy life to the community, and a second dealing with occupational disease and the way in which industry falls short of its high calling.

Hysterical Disorders of Warfare. By LEWIS R. YEALLAND, M.D., Resident Medical Officer, National Hospital, Queen-square, London. With Preface by E. FARQUHAR BUZZARD, M.D., F.R.C.P., Lieutenant-Colonel, R.A.M.C. London: Macmillan and Co. 1918. Pp. 252. Price 7*s.* 6*d.* net.

Dr. Yealland's readable volume on the hysterical disorders of warfare appears at a time when it is likely to prove of immediate and practical usefulness to the medical profession. Considerable numbers of cases of hysteria are being dealt with in special and in general military hospitals, large and small, and by boards, pension committees, and individual medical men. Such cases cannot be satisfactorily handled for therapeutic purposes except by active, intelligent, immediate, persuasive tactics on the part of the individual who will devote himself to each particular case. Treatment cannot be allowed to devolve on deputies if successful results are to accrue; the problem is that of one mind *versus* another, and its solution demands unremitting application on the part of the therapeutist. The reward is worth the mental labour, however, for in this field, above all others, nothing succeeds like success, and each cure is not merely an incentive for further triumphs, but is a potent factor in the establishment of that easy and reliable self-confidence the possession of which is half the battle.

Various methods of psychotherapy are in vogue at present for the treatment of hysteria. The exponent of hypnotism, or psycho-analysis, or of suggestion without apparatus may obtain results satisfying to himself and pleasing to his own views of the nature of hysteria; others, less concerned with psychological theories, may give the patient a whiff of ether and obtain just as good and as lasting effects. Dr. Yealland is an accomplished exponent of treatment by means of a combination of electricity and mental persuasiveness, which in his hands, judging by his records, has proved literally irresistible. Apparently he has not had one single failure out of hundreds of cases, for which he deserves cordial congratulations. Every variety of hysterical phenomenon has been met and successfully combated; not merely the simple case of flaccid palsy of short duration, already half-cured by auto-suggestion ere the seance begins, but the complex and difficult case of functional spasm of accommodation, which has required many hours of continuous treatment for its exorcism. Dr. Yealland enters into the minutest details of his particular technique, and a perusual of his selected cases will provide adequate information for all who desire to learn and practise this particular method. Incidentally, the author unconsciously reveals the secrets of his unfailing success—ingenuity of application of the method, nimbleness of mind in the presence of unforeseen hitches, imperturbability of temper, patience and persistence which have gone to almost incredible lengths, enthusiasm, above all, an insight into the mind of the sufferer without which no amount of electricity would effect a cure.

If there is no special analytical investigation of the phenomena from a psychological standpoint, the value of the method is not thereby lessened. Dr. Yealland shows how potent is the fact of relief of symptoms in itself re-enforcing and consolidating the therapeutic gain, so that instances of relapse are few and far between. The book is written in an easy, colloquial style, and, apart from the details of the method in a large variety of cases, also contains useful diagnostic criteria between organic and functional nervous disease.

THE LANCET.

LONDON: SATURDAY, AUGUST 24, 1918.

The Drug-supply after Four Years of War.

THIS country has depended upon overseas sources for its supply of most of the important vegetable drugs before the war; and before the war the whole world drew practically all it needed in the way of the so-called "newer remedies" from Germany. But when need drives we can do without Germany. It is true that all drugs are relatively scarce and many of them very costly at the present time, but among the thousand and one materials inside and outside the Pharmacopœia those which are absolutely unprocurable can be counted on the fingers of one hand, while it is perhaps safe to say that not a single essential drug has entirely vanished from the shelves of our chemists' shops—a tribute to the power of our Navy. When the market sections of the drug papers speak of a drug as being scarce it must not necessarily be inferred that the drug is being produced only in small quantities; the accurate inference is that the quantity available for distribution through the druggists to the civil population is greatly reduced, for we must remember that the demand for drugs from the medical services of our own and our Allies' Armies has to be met first. This is a not unimportant point, and we draw attention to it in order to emphasise the fact that when a drug is reported to be scarce it does not mean that sick and wounded soldiers lack the proper remedial agents. Then, again, it is common knowledge that glycerin is difficult to obtain and that castor oil of the best quality cannot be bought in the open market. But there is no intrinsic scarcity of either of these substances; they are being produced in quantities far exceeding the pre-war output, but the whole of the production is required for purposes other than those medicinal. Thus, taking a broad view, we have much to be thankful for. Notwithstanding the U boats, trading vessels are bringing to port those vegetable drugs that cannot be produced in our soil and climate, and though freights are amazingly high, cargoes much reduced in weight, and ships less frequent and longer in passage, the storehouse is never empty. If there is no Turkish opium to be had there is a sufficiency of Persian; if we do not import quinine from Germany we can secure a goodly proportion of the product of the Dutch factories, or we can make quinine here from the cinchona bark of Java.

The keeping up of a regular supply of synthetic products presents a wholly different problem. Germany had, as everybody knows, secured a practical monopoly of the dye industry, and the synthetic production of drugs was an offshoot of that industry. When war broke out nobody foresaw how long it would last, and nobody appears to have begun at once to make preparations to produce synthetic drugs on a scale adequate to supply the country's needs in the event of a long war. The American chemists were not hampered like our own manufacturers were, and they got to work before us. But the necessity of establishing a fine chemical industry in this country was recognised in due course, and, after the initial problems had been solved, our chemists were able to produce some of the more commonly prescribed compounds in commercial quantities. In France, Spain, Holland, Japan, and especially in Switzerland, and even in some of our own overseas dominions, the drug industry has now been established. The result is that the world has been able to make itself independent of Germany; and if it can do this in war-time we may be sure that it will be able to do it when labour becomes plentiful and the scarcity of raw materials is no longer a factor to be reckoned with. In his altogether admirable address at the Fifty-Fifth Annual Meeting of the British Pharmaceutical Conference, Mr. C. A. HILL, the President, mentioned salicylic acid, aspirin, phenacetin, hexamine, and saccharin as substances which are being produced here on a regular scale. He did not extend the list further, but he did something more reassuring; for he said flatly, that "whenever a particular substance has been required for a particular purpose, British chemical science *plus* British chemical industry have not failed to produce it in requisite amount and of requisite purity within a reasonable time." Now all this is true enough, but it is important, in view of the future, to add Mr. HILL'S proviso that, "questions of cost apart, the thing can be done." Lord BALFOUR'S Committee on Trade After the War recommended that during a specified period British manufacturing chemists should be given very generous protection, so as to encourage them to establish here the synthetic drug industry on a large and permanent basis. We hope that the "questions of cost" will not be too far "apart." This class of drug can and should be produced here at a price which will allow of the products being sold for sums approximating to those which they would fetch if imported from abroad.

We have sufficient confidence in the chemical skill and commercial acumen of our manufacturers to believe that the public would not suffer unduly as a result of the protection recommended. The President of the British Pharmaceutical Conference in his address did not make the mistake of leading us to think that we had made any remarkable progress in the synthetic drug industry. We have made a good beginning, it is true, but the manufacture of some of the drugs mentioned has been, as he told the Conference, an industry *ad hoc*. Obviously this will not meet after-war conditions, for the production of synthetic drugs on an economical scale must necessarily be part and parcel of a large and general scheme. It is in the imaginative lay mind that the danger lies, and it is to be hoped that the Exhibition of British Scientific Products now being held at King's College

will not have the effect of impressing the public with the belief that so far as the production of drugs is concerned our difficulties are over. Those behind the scenes will tell us that we are only at the beginning. Nevertheless, as an account of this exhibition in another column shows, a good beginning has been made, and there is no reason why progress should not go on provided that the movement receives the whole-hearted support of the public and the assistance of the Government when the strife is at an end. It is clearly demonstrated that British manufacturers are thoroughly capable of supplying us with products of a quality as good as, if not better than, those hitherto supplied from foreign sources. Their patriotic enterprise deserves all the encouragement it is possible to give. Medical practitioners need not be reminded how intimate is the relationship of the manufacture of dye for stuffs to the production of these drugs; and it is to the great dye factories, rather than to the druggists, that we must look for the development of the industry. Before the war we visited some of the most important of the German dyestuffs factories; the visit impressed upon us the fact that a successful synthetic drug industry depends upon a successful dyestuffs industry.

Industry and Medical Service.

FUTURE students of the social revolution of the nineteenth century, the result of sudden and unprecedented industrial development, will wonder at the blindness of the medical profession to the altering conditions around them; they will wonder that, even in the twentieth century, medical men continued to work on the plan handed down to them by their seventeenth- or eighteenth-century forbears, who practised among a clientèle busied with agriculture or home industries, and who were closely acquainted with the daily life of their patients, and thus able to dispense general advice as well as drugs and professional counsel. One definite opening occurred to keep the profession in touch with industrial patients, an opening of which but little advantage has been taken—doctors, when the Factory Act of 1833 fixed a limit of age to juvenile employment, at a time when birth certificates were unknown, were called upon to certify the age of children presenting themselves for employment, and were allowed to charge the child a fee of 6*d*. With the introduction of birth certificates the *raison d'être* of the work was changed, and the certifying surgeons were asked, in addition to inspecting the birth certificate, to certify the fitness of the child or young person for the proposed employment. The fee has remained the same, although in 1878 the employer was called upon to pay half of it, and since 1891 the whole. Controversy has centred round the place of examination, whether it should be at the surgeon's rooms or at the factory; but the controversy has been suspiciously associated with the fact that a visit to the factory is remunerated at 2*s*. 6*d*. for certifying five or less youngsters. Here the position stands to-day, and since the ridiculously low fee of 6*d*. produces the value of 6*d*., it has been aptly said that the certifying surgeon is paid either too much or too little. Too much for what he does, or too little for what he ought to do—certainly too little if the instructions now issued by the Home Office relating to the examinations are observed.

The truth is the medical profession has not seized the chance to make its weight felt when visiting industrial establishments, by examining the processes carried on and the places where they are carried on, and by advising on factory hygiene. Exceptions there have been, especially in recent years; and factory managers are here and there learning to appreciate the value of a doctor in connexion with employment. The services he can render are becoming obvious in these days of compensation for accident and disease, and of scientific management and standards of efficiency which call more and more for the alertness of health. And, as we have said elsewhere this week, in reviewing a valuable treatise upon occupational hygiene and pathology, the present war has brought home to all nations their utter dependence upon industry, while it is essential that this country, the mother of inventions and modern trade, should not fall behind in any organised plans for benefiting the medical conditions of the workers. Our feeling is that the certifying surgeon should examine not merely juveniles, but adults on engagement, organise first-aid treatment, point out unhygienic conditions of work—poor lighting and bad ventilation—advise on unhealthy posture and excessive weight-lifting and on hours of work in relation to rest, pauses, and meal-times. More should be given to the certifying surgeon to do, and the emoluments should rise accordingly.

At the present moment we should prefer to see development on these lines rather than some soothing of the ruffled feelings of certifying surgeons by granting them an increase of fees, up to possibly 1*s*. a head of those examined, a suggestion which, we understand, is being put forward. That the present fees are inadequate is obvious, but it is the work of the certifying surgeon which is to-day wrong, and is especially in need of being recast now that the whole system of medical practice is awaiting reorganisation. Good work never exists long without recognition, and we hope, even if the present grievances remain unremedied until the Ministry of Health is established, that ere long the medical profession will be brought closely in touch with industry, and that every factory will have its medical adviser, not merely certifying youngsters on engagement, but following them up by periodical examination and studying the effect of particular employment upon their physique and health—carrying on, indeed, the work of the school medical officer, with whose records the certifying surgeon should be acquainted. Here is a new field of medical activity the importance of which is already being tested and proved by the Ministry of Munitions with its whole-time medical services in certain factories; and it is a field which must be cultivated if health, which is the basic wealth of a nation, is to be raised to a level where industrial efficiency is given its best opportunities.

Annotations.

"Ne quid nimis."

THE CASE-MORTALITY OF INFECTIOUS DISEASES.

THE annual report of the Metropolitan Asylums Board for 1917 appears in the abbreviated form to which the exigencies of war have accustomed us. But the absence of charts and tables does not do much to diminish the interest excited by the changing values of the case-mortality for the various common infectious ailments. In the case of scarlet fever and diphtheria the death-rate has not altered materially. Together these two infections account for more than three-quarters of the total admissions to the hospitals of the Board, and the death-rate is therefore built on large numbers. The figures for 1917 were 1·9 and 6·7 respectively, being only a single point different from the 1916 figures, plus in the case of scarlet fever, minus in the case of diphtheria. It is apt to be forgotten that while in the last decade of the nineteenth century the case-mortality of diphtheria rapidly fell, as a result of antitoxic treatment, from over 30 to its present figure, the case-mortality of scarlet fever has fallen in about the same proportion, but more gradually, from year to year since the earlier "seventies," when it was above 12, to its present value below 2. In the case of the four other acute infectious fevers with which the Board has dealt during the year the death-rate shows in each case a rise of roughly one-quarter on the 1916 figure. Fortunately in the case of enteric and cerebro-spinal fevers the total number of admissions is but small—enteric, 172; cerebro-spinal, 101—but none the less the death-rate of 17·3 in the former and 53·7 in the latter is worthy of serious thought. Progress in regard to both has been on the side of prevention rather than of treatment. The total deaths are such as to warrant more continuous effort than has yet been given to improvement in the clinical treatment of these diseases. The numerical aspect is quite otherwise in the two remaining infectious fevers of uncertain etiology. 2951 cases of measles were admitted during 1917 to the hospitals of the Board, and of these 11·7 per cent. died; 391 cases of whooping-cough, and of these 13·4 per cent. died. The death-rate in the case of whooping-cough is the highest on record, in the case of measles higher than any figure since 1911. In neither instance, of course, does the death-rate of patients in the Board's hospitals give any clue to the average case-mortality outside, because it is only the cases with serious complications, for the most part broncho-pneumonia, which are admitted. But making all allowance for this circumstance, the figures in the 1917 report reveal measles and whooping-cough once again as the dangerous plagues which they are to the town child under present social and hygienic conditions, and justify any possible speeding-up of the scheme for home nursing which the Local Government Board has set in action and subsidised by grants-in-aid.

DRIED VERSUS CONDENSED MILK.

THE official résumé (THE LANCET, July 13th, p. 55) of Dr. F. J. H. Coutts's report to the Local Government Board on the rôle of dried milk in infant feeding has brought us an eloquent plea from across the channel for the claims of sweetened condensed milk for hand-fed babies, and at the same time for an international solution of such a many-sided problem as the artificial feeding of infants. Our correspondent, Dr. P. Lassablière, is chef de laboratoire to the Faculty of Medicine in Paris, and speaks on the basis of an experience of several years with more than a thousand hand-fed babies, of whom some hundreds were brought up exclusively on condensed milk. The passage in the Local Government Board's résumé on which he bases his remarks is as follows:—

> Sweetened condensed milk is often used for baby feeding. Dried milk has the advantage, when made up with the proper proportion of water, of containing the essential food elements in a proportion more suitable for the baby than when full-cream sweetened condensed milk is used. The latter, if made up so as to give the right proportion of fat, has a very excessive amount of sugar. This is not good for the baby, who usually becomes fat and flabby, and is liable to suffer from diseases such as rickets, &c.

Dr. Lassablière states that all the babies under his care brought up on condensed milk showed a normal growth and no signs of scurvy or rickets after 14–18 months or more of its use. More than this, in a number of babies whose growth had been retarded by digestive troubles, a change to condensed milk was accompanied by a return of digestive power and of normal development. He has seen no harm follow the excess of saccharose in the milk mixture, and agrees with Dr. J. I. Fanz, of Jefferson Medical College, in believing[1] that even in young babies saccharose is hydrolysed by the enzyme "invertine" to an extent not generally admitted. Dr. Lassablière finds in the laxative action of the saccharose a definite point of value for the hand-fed infant, which would justify the excretion of a certain quantity unchanged, if this is in fact what takes place. He quotes with approval Professor Lo Monaco's recent observations on the influence of saccharose on the digestive glands. Finally, he explains the divergent experience of medical men in regard to the effect of condensed milk on babies by the different dilutions adopted, and to some extent by the differing quality of the brands of milk on the market. Unsweetened condensed milk he considers positively dangerous. Dr. Lassablière concludes his letter with an excursus on fashions in medical theories and opinions, and asks to have condensed milk judged by the test of controlled clinical observation. In this country at the moment the shortage of sugar might stand in the way of such a test.

NASAL BREATHING IN THE TOWN CHILD.

To snivel or to snuffle is such a familiar habit of the small child in poorer town areas that it excites no interest and barely any annoyance in the family circle, the mother or elder sister being content to wipe away with any old rag the mucus or muco-pus actually visible outside the nose. But it is the secretion within the nasal cavities which alone is of importance, and its accumulation effectually prevents the free nasal breathing which is as important to healthy development as free nutrition and excretion. Some relation between adenoid vegetations in the naso-pharynx and chronic nasal catarrh is generally recognised, although doubt may arise as to which is cause and which is effect. In a clinical note which we publish this week Dr. Isabel Ormiston deals with a method of treating adenoids by means of a nasal drill designed to keep the

[1] New York Medical Journal, 1915, i., 253.

breathing passages free from obstruction by secretion. Older children are taught regularly to blow their noses without constricting the orifice in a way which expands the chest at the same time. In children too young to do this the same result is obtained by the application of an iris-root snuff to produce sneezing. Dr. Ormiston admits that she was sceptical of the method when it was brought to her notice by its inventor, but after trying it herself for four years and in an experimental clinic for six months with Dr. Octavia Lewin, she has become convinced of its value. In children with adenoids she finds the first improvement in the digestive system, followed by relief of deafness and by a steady shrinkage in the adenoid growths. Both the cases which Dr. Ormiston cites were found to be better in the summer, the usual history with such children, and it may be contended that the method is only likely to be successful in cases where ordinary systematic breathing exercises would also have succeeded. But there is no doubt that the drill is an effective way of performing the very necessary nasal toilet, and results on a larger scale will be looked for with interest.

SPIROCHÆTAL BRONCHITIS.

MORE than ten years ago Castellani discovered in Ceylon a form of bronchitis due to a microbe which he termed *Spirochæta bronchialis*. Since that time cases have been described in various parts of the world. At a recent meeting of the Académie de Médecine of Paris Dr. H. Violle reported what appear to be the first cases of this curious affection observed in France. During three months he has seen 30 cases in the naval hospital of Saint-Mandrier, Toulon. The sputum is bloody, viscid, and of a uniform rose tint resembling gooseberry juice. The colour is not observed in any other affection, and hence is diagnostic. Dr. Violle therefore proposes the title "bloody bronchitis." Some of the patients were admitted with the diagnosis of phthisis, but repeated examinations of the sputum failed to reveal the tubercle bacillus. On the contrary, smears stained with nitrate of silver showed spirochætes, sometimes innumerable, of all forms and dimensions, some long and fine, others thick and squat, with various undulations. Often these organisms were almost in a state of purity, sometimes they were associated with other microbes. Blood examination revealed slight anæmia, probably due to the repeated hæmoptysis. The affection is relatively benign; the onset is insidious, the general condition is good, there is no fever, but headache occurs. The pulmonary signs are slight and sometimes are absent. Often they are those of ordinary bronchitis, sometimes of apical bronchitis, or of congestion of the bases. Cough is frequent and may be painful. The sputum sometimes is abundant and may regularly be hæmorrhagic or muco-hæmorrhagic alternating with muco-purulent. Relapses are frequent. It is important to recognise the affection, as it is very contagious. It appears to have been introduced into France by Asiatic troops or workers, or by troops which had been in the Levant. The disease has become acclimatised in France—in the south, at any rate. A quarter of the patients were Frenchmen. The affection may be complicated by graver affections, such as tuberculosis, pneumonia, or broncho-pneumonia, the germs of which evidently enter the lung through the breaches made by the spirochætes. A look-out should be kept for the carriers.

THE REAL BOTULISM.

THE most recent monograph (No. 8, July 31st, 1918) of the Rockefeller Institute for Medical Research is devoted to a clinical and experimental study of botulism by Dr. Ernest C. Dickson, from the Stanford University Medical School at San Francisco. Dr. Dickson's interest in the subject dates from an outbreak which occurred in December, 1913, after a banquet in a students' club house, when the only article of food taken by all the 12 students attacked was a salad of string beans (presumably the equivalent expression for our runner beans) prepared at the home of one of the members of the club. The *B. botulinus* was not recovered from the organs of the one student who died, and all the salad had been eaten, leaving none to examine; but the clinical picture was typical of botulism, and the peculiar type of thrombosis in the blood-vessels of meninges and brain, since shown experimentally to be characteristics of botulism, was first demonstrated in the fatal case by Professor W. Ophüls, pathologist of Stanford University. Since this time Dr. Dickson has investigated a number of outbreaks on the Pacific coast of America, and has succeeded in isolating three strains of the infecting organism, twice from the crops or gizzards of chickens which had died after eating string beans or discarded maize, and the third time from a can of string beans, fellow to one which caused poisoning among a party of 15 at an hotel dinner at Escondido, California, in January, 1917. In this as in other outbreaks the most striking symptom was progressive muscular weakness, especially marked in the muscles of the head and neck and called by the expressive name "limber-neck" when it occurs in domestic fowls. In one outbreak the condition is described thus:—

> "There was extreme flaccidity of the muscles of the neck, allowing the chin to rest upon the chest or the head to fall backward if not supported when the patient was elevated. It was a common occurrence to see a patient move her head with her hands, and one girl who had long braids used them, with the head of the iron bed as a pulley, to swing her head into position when she wished to move. The head could be rotated and held from falling to either side, but the anterior and posterior supports were lacking."

The monograph will be read with keen interest by all those who found a close resemblance to the symptoms of botulism in the epidemic encephalitis of a few months ago. Dr. Dickson's monograph is of special value because it shows that botulism, while endemic in the United States and comparatively common on the Pacific coast, is not essentially a meat poison, but may also occur in canned vegetables and fruits. He advocates a campaign of education to inform those who can fruits and vegetables of the danger of infection with *B. botulinus*.

Colonel William R. Smith, M.D. Aberd., D.Sc., F.R.S. Edin., Sheriff of the City of London, professor of forensic medicine in King's College, London, and Principal of the Royal Institute of Public Health, is a candidate for the Parliamentary representation of the Universities of Scotland.

THE identity of Mr. A. Stanford Morton may not have been generally recognisable under his official description as Dr. Andrew Morton in the list of honours conferred by the King of Italy (THE LANCET, August 17th, p. 215).

BY an Order in Council, dated August 14th, the provisions of the Parliament and Local Elections Act, 1918, have been extended to the election of Members of the General Medical Council by registered practitioners resident in the United Kingdom, the effect of which is to extend the term of office of the existing Direct Representatives until Dec. 31st, 1919.

THE BRITISH SCIENTIFIC PRODUCTS EXHIBITION.

AN inspection of this interesting exhibition showed that there were in all 14 sections distributed amongst the class-rooms, theatres, hall, and corridors of King's College. Many sections related to great industrial processes, as those concerned in the production of textile fabrics, paper, ferrous and non-ferrous metals, glass, refractory materials (firebricks, carborundum). We confine ourselves, however, to brief notices of those products which have an important bearing on the position of medical science. These sections all told the same story; they served to illustrate our dependence for supplies in the past on enemy countries and our independence for these supplies in the future. It is obvious that the exhibits could not complete the tale of our scientific indolence in the past, since many products have been obtained which it would not be in the public interest to exhibit. The sections of direct interest to medical men were three in number: Section I., Chemical Products and Processes; Section IV., Optical Apparatus; and Section VIII., Surgical, Bacteriological, and Pathological Appliances.

SECTION I.—CHEMICAL PRODUCTS AND PROCESSES.

This section was perhaps more eloquent than any other of the resources of British science, particularly in the direction of building up synthetics. The Gas Light and Coke Co., of Beckton, E. 16, for instance, exhibited a most interesting series of chemical substances chiefly the products of coal tar, the parents of so many synthetic drugs, amongst which may be mentioned beta-naphthol, salicylic acid, acetyl salicylic acid (the aspirin of German manufacture), ammonium salts, and cyanogen products. In addition, there were fine specimens of carbolic acid in both glacial and detached form. Messrs. Evans, Son, Lescher and Webb, Ltd., of 56, Hanover-street, Liverpool, showed an attractive series of drugs, all evidencing careful scientific preparation. Amongst these were atropine and hyoscyamine, bismuth tribromophenol (hitherto familiarly known as xeroform), chlorophyl, hexamine, lanoline, salvarsan and sodium sozoiodolate, and thymol, formerly imported from Germany, but now obtained from raw material grown in India. Messrs. Evans, Gadd, and Co., of 100, Fore-street, Exeter, exhibited fine examples of lysol. The exhibit of the British Drug Houses, Ltd., of 22-30, Graham-street, City-road, N. 1, comprised some 80 samples of chemical preparations representative of the extension in the domain of fine chemical manufacture which this company has made during the war to meet the demand for products hitherto obtained from Germany. These included bismuth, tribromophenate of bismuth (German xeroform), thymol iodide (German aristol), iodatol (German iodopin). Similarly were shown microscopic reagents and dyes and standard analytical reagents, all formerly supplied from Germany. Altogether this exhibit was a quite impressive one, having regard to the object of demonstrating that what the Germans could do the British could do. Messrs. Boots Pure Drug Co., Ltd., of Nottingham, presented an interesting series of fine pharmaceutical products; amongst these were acriflavine, acetanilide, aspirin, atropine and its salts, butyl chloral hydrate, cantharadin, chloramine, and di-chloramine T, digitalin, halozone, hexamine, homatropine and its salts, hyoscyamine, phenetidin, proflavine, saccharin, salicylic acid, soluble aspirin, theobromine salicylate, and tropine. Amongst the exhibits of The Bradford Wool Extracting Co., Ltd., of Pit Lane Mills, were some fine chemicals, including phenacetin, salicylic acid and its derivatives, and acetanilide. As examples of chemicals illustrating the manufacture from raw potash material produced in this country, the British Cyanides Co., Ltd., of Oldbury, Birmingham, exhibited specimens of carbonate and bi-carbonate of potash, the permanganate, ferrocyanide, and chloride. The products of the "Wellcome" Chemical Works (Messrs. Burroughs, Wellcome and Co., Snow Hill Building, London, E.C.) formed an interesting exhibit of synthetics, notably kharsivan and neokharsivan, replacing the German salvarsan and neo-salvarsan. Similar replaced products were hexamine (syn., German urotropine), phenacetin, aspirin, among a number of fine chemicals used in medicine. Pilocarpine, atropine, eserine and homatropine and their salts were made on a commercial scale by this firm several years before the war broke out, and the researches carried out in their laboratories have produced "ernutin," a synthetic product presenting the active therapeutic principles of ergot, and emetine hydrochloride and emetine bismuth iodide. The Chemical Research Laboratory of the University of St. Andrews contributed some instructive specimens illustrating the manufacture of synthetic drugs in this country. No less than 25 fine chemicals, including novocain and orthoform, were shown and now prepared on the manufacturing scale by processes developed in the above laboratory since the outbreak of the war. Luminescence chemicals were the attractive feature of the exhibit of the Cold Chemical Co., of 13, Canal-road, Kingsland-road, N. 1. Amongst these were calcium tungstate, the basis of X ray intensifying screens, and cadmium tungstate and synthetic willemite fluorescent materials for the same screens. Sir William Crookes exhibited specimens of anti-glare glass, which, used in spectacle lenses for our troops and airmen, is doing good service, and also in munition work in which the workers are exposed to powerful light and heat rays. By the addition of various metallic oxides the glass acquires the dual property of arresting both the ultra-violet and the heat radiations. Messrs. Hedley and Co., of 120, Harrow-road, Leytonstone, showed specimens of ethyl chloride, bromide, and other related ethers used in anæsthetic practice. Ethyl chloride was manufactured in Germany to the extent of hundreds of tons both for the manufacture of pharmaceutical products and "intermediates" in dye production. An interesting series of organic compounds, the manufacture of which has been undertaken since 1914, was exhibited by Messrs. Thomas Kerfoot and Co., of Bardsley Vale Mills, Bardsley, Lancs. These included "kerocain" (Kerfoot's novocain), phenacetin, acetyl salicylic acid, and a number of chemical materials essential in the manufacture. Messrs. Boake, Roberts, of Carpenter's-road, Stratford, London, had a very interesting collection of organic salts, including acetates, formates, butyrates, and salicylates, and there were also shown specimens of formaldehyde, paraldehyde, and hexamine. Such is a rapid review of the more important preparations of medical interest in this section, all illustrating our independence of enemy supplies in the future, and the remarkable results which have followed our awakening to the need of applying science to the production of many essentials in medical practice.

SECTION IV.—OPTICAL APPARATUS.

The exhibits in this section are the outcome of this country finding itself at the outbreak of the war cut off from a supply of optical glass required in the construction of gun-sighting telescopes, field-glasses, and other service instruments. The essential constituent of certain glasses is potash, of which Germany possesses favourable sources. Now ample supplies of potash of high quality are produced by electrolysis in this country, with the result, as Professor R. A. Gregory says, that "glass-makers will never need to go to Germany again for this substance." We refer to the important results shown in this section because they clearly have a bearing upon the efficiency of medical investigation in which good lenses are a *sine qua non*, as in laryngoscopy, microscopic work, and bacteriology.

SECTION VIII.—SURGICAL, BACTERIOLOGICAL, AND PATHOLOGICAL APPLIANCES.

The importance of a supply of high-quality glass in medical practice was further illustrated in the exhibit of artificial eyes by Mr. Albert E. Waters, of the Empire Works, Mole-street, Sparkbrook, Birmingham. Prior to the war, it is stated, the major portion of the artificial eyes used in this country were imported from Germany. These eyes are now superseded by a British-made artificial eye superior to the German article in every particular. Messrs. Allen and Hanburys, Ltd., of 48, Wigmore-street, London, W., exhibited an improved cystoscope, giving large-field upright image and sharp definition. Constructed on the same principles is a cystoscope for the combined irrigation of the bladder and catheterisation of the ureters. It is fitted with channels through which ureteral catheters can be passed, and there is also an improved rubber valve which can easily be rendered sterile and

replaced when necessary. The British Laboratory Ware Association, Ltd., of 24, Martin's-lane, Cannon-street, London, E.C., exhibited well-known forms of apparatus used in bacteriological practice; all testify to the excellence of British manufacture. Amongst the exhibits of Messrs. Chas. W. Cook, Ltd., of University Works, Bridge-street (Owens College), Manchester, were a hand-press and filter designed by Professor Delepine for aseptically extracting pulp of juices from fresh tissues, and a microtome by the same designer for cutting large sections of animal tissue and for paraffin wax and other sections when using the freezing method. The manufacture of fluorescent and intensifying screens used in X ray work was practically a German monopoly, but Messrs. Harry W. Cox illustrated in their interesting exhibit how the enemy has been beaten in this direction. Messrs. Hawksley and Sons, of 357, Oxford-street, London, W. 1, exhibited their hæmacytometer, the feature of which is the special form of counting chamber. An all-glass hypodermic syringe, an ampoule syringe, a blood "extractor," and double-channel glass catheters, formed the novelties on the stall of Hyposol Limited, of High-road, Wealdstone, Harrow, while Messrs. S. Maw, Son, and Sons, Ltd., of 7–12, Aldersgate-street, London, E.C. 1, showed hypodermic syringes, together with antiseptic dressings and the "limpet" nail-brush for one-armed men. A very representative and up-to-date collection of surgical instruments was shown by Messrs. Mayer and Meltzer, of 71, Great Portland-street, London, W.1, most of them referring to war surgery and made since the war began. The exhibit included Shipway's warm anæsthetic vapour apparatus, already described in our columns. Mr. W. J. D. Roberts, of 81, Mortimer-street, London, W. 1, showed an improved stretcher, the chief claim of which is that the canvas is easily removed for the purpose of cleaning and sterilising, thus reducing the risk of infection to the patient. The exhibit of the Surgical Requisites Association, of 17, Mulberry-walk, Chelsea, referred chiefly to splints, as, for example, the papier-mâché splint, made on an actual cast of the affected part, so securing an accurate anatomical fit. The material is light, non-inflammable and waterproof, and, what is of some importance, transparent to X rays. A thoroughly representative exhibition of typical serums, vaccines and tuberculins was given at the stall of Messrs. Burroughs, Wellcome, and Co., all these being products of their research laboratories at Herne Hill, London.

We have attempted to deal with only those sections of the exhibition which give ample illustration of what British scientific effort is doing to ensure for medical science the efficiency of its material and equipment and to secure them entirely and satisfactorily within our own country or dominions. It need hardly be added that the other sections included industrial developments of the greatest importance to the nation's position in the world, developments which will advance more and more as science is brought to bear on the methods of production.

REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1916.

THIS annual report on the health of the population of India is as comprehensive and clearly arranged as in former years. It deals with the health conditions of 315 millions of people (about three-fourths of the population of the British Empire), including those of the European and Indian armies, the prisoners in jail, and the civil population generally, and gives an account of the various medical institutions, hospitals, dispensaries, medical schools and colleges, and laboratories for research work throughout the country.

Health of the European Army in India.

It is pointed out by the Director of Medical Services in India at the commencement of the portion of the report dealing with the health of the European troops, that, on account of the war conditions prevailing, any "comparison with statistics previous to 1914 must take into account the following factors: a continual outflow of healthy individuals to overseas forces, while soldiers unfit for active service are retained in India; this automatically raises the proportion of unfit men to the total strength; the lower standard of physique required for garrison battalions; a continued ingress into India from overseas forces of debilitated men who are more susceptible to disease; and the advent of large numbers of unacclimatised men straight from Europe with a susceptibility to tropical diseases." The average strength of troops (Regulars and Territorials) during 1916 was 60,737 warrant and non-commissioned officers and men. The admissions to hospital from all causes were in a ratio of 772 per 1000, the number constantly sick averaged 39·75, the deaths 6·54, and the invalids sent home 22·11 per 1000. Compared with 1915, when the admissions had been 823·1, the constantly-sick 39·08, the deaths 5·95, and the invalids 19·80 per 1000, all the ratios except that for admission to hospital are higher, and compared with the ratios for the preceding five-year period (1911–15) there is a considerable increase in every case, the quinquennial ratios having been 601·2, 31·06, 4·51, and 8·68 respectively. There is, however, no return to conditions such as prevailed in the period, 1881–1890, when the constantly sick averaged 73 and the deaths 14·79 per 1000. The chief causes of death from disease in 1916 were heat stroke (45 deaths), enteric fever (33), pneumonia (33), cholera (19), malaria (19), and dysentery (18). The healthiest parts of the country appear to have been Southern India and Upper Burma; in the former region (including Bangalore and Madras) the admission and constantly-sick ratios were only 501·9 and 28·7 per 1000 respectively; in Burma Inland (or Upper Burma) these ratios were 598·5 and 29·5 per 1000. The troops on the western coast, mostly at Colaba (Bombay), showed the highest constantly-sick ratio (58·7 per 1000), the admissions being in a ratio of 886·5; while those on the North-West Frontier (Peshawar, Nowshera, &c.) had the highest admission ratio (1116·5), the constantly sick averaging 45·7 per 1000. The chief large stations (with over 1000 effective strength) that showed excessive sickness were Sialkot (1326·3 admissions per 1000, of which 543·5 were due to malaria), Nowshera (1291·0, of which 457·8 malarial), Peshawar (1270·8 and 679·2), Ahmednagar (1070·9 and 380·6), Lahore (1009·9 and 162·6); the constantly sick ratios in these stations were 62·9, 56·1, 47·1, 41·1, and 50·6 respectively. On the other hand, Poona had only 610·1, Secunderabad 544·3, and Bangalore 481·9 admissions per 1000, the constantly-sick ratios being 46·7, 30·8, and 27·7 respectively.

Malaria was in 1916, as always, the predominating cause of inefficiency among British troops in India, and was more prevalent than in any year since 1909: there were 186·0 admissions and 0·31 deaths per 1000, compared with a quinquennial average of 123·1 admissions (1911–15) and 0·23, respectively, for 1911–15. The North-West Frontier group of stations suffered most with an admission ratio of 442·4 per 1000, Peshawar itself, with a garrison of 2363 European troops, having 679·2 per 1000, the most severe prevalence in the past seven years. Owing to frontier disturbance the troops had to be brought down from the hills earlier than usual. There was also an excessive rainfall. The general increase in malaria throughout the country is considered to have been largely due to the endemicity of the disease in certain garrisons of Northern India; the existence of active "carriers" among troops returning from overseas; the presence of a large proportion of young, unacclimatised soldiers, category B men, and garrison battalions; abnormally high rainfall at certain stations; and frequent and unavoidable changes of medical personnel. In addition sandfly fever caused 45·9 and pyrexia of uncertain origin 7·4 admissions per 1000, compared with 41·1 and 9·8 respectively in 1915; 6 deaths were due to the latter disease. Enteric fever caused 5·2 admissions and 0·54 deaths per 1000; in the decennium 1906–15 these ratios had been 7·3 and 1·28 respectively. The admission ratio was higher than in 1915 (3·7); higher, indeed, than in any year since 1909, the year in which effective inoculation was introduced. At certain stations there were actual epidemics, though on a small scale compared with those of former years; thus, at Bangalore there were 59 admissions for fevers belonging to the "enterica group" (16·7 per 1000), 5 only being actual enteric, while 51 were paratyphoid A and 3 paratyphoid B; at Nowshera there were 28 cases (13·9 per 1000) and at Peshawar 30 cases (12·7 per 1000); at Bombay there were 17 cases (10·6 per 1000). Carrier infection was suspected at each place and fly infection also at Nowshera. There was an increase in the prevalence of dysentery (8·2 admissions per 1000), the quinquennial ratio (1911–15) having been 6·0

per 1000 (though the ratio for 1906–15 was 9·1); it prevailed chiefly in Southern India, as at Bangalore, where there were 24 4, and at Secunderabad 23·5 admissions per 1000. Plague caused 8 admissions and 4 deaths; 4 of the cases occurred at Poona, none of which were fatal. For cholera there were 50 admissions and 19 deaths; 8 of the cases (with 5 deaths) occurred at Meerut. The incidence of venereal disease was higher (36·8 per 1000) than in 1915, but lower than in any previous year in recent times; for the decennium 1906–1915 it has averaged 66·3. At Calcutta the admissions were 151·1 and at Bombay 114·5 per 1000; while, on the other hand, at Lucknow this ratio was 47·9, at Jubbulpore 42·4, and at Rawalpindi 37·1 per 1000. Some explanation should surely be forthcoming as to these wide variations in prevalence. At Poona (where the venereal admission ratio was 54·6 per 1000) it was noted that 50 per cent. of the infection had been contracted in the United Kingdom, France, or Egypt. Heat-stroke (including sunstroke) accounted for 347 admissions and 45 deaths, giving ratios of 5·8 and 0·74 per 1000 respectively. At Ferozepore there were 94 6 admissions per 1000 for this casualty, at Lahore 62·0, at Multan 32·7. A large number of cases (136) occurred on a troop train travelling between Karachi and Peshawar in June, which were admitted to various hospitals en route; 19 of these were fatal. The mortality ratio for all India from this cause (0·74 per 1000) was more than double that for the decennium 1906–15, which had been 0·35 per 1000. Thirty-five victims of dog-bite were treated at the Pasteur Institutes at Kasauli and Coonoor; only 2 cases of hydrophobia occurred; one was treated at Kasauli, but subsequently developed the disease and died; the other, also a fatal case, who had been bitten by his own dog, did not report sick until the disease had developed.

Health of the Indian Army.

The average strength of Indian troops, including 2531 in China, Ceylon, and Somaliland (but excluding those on field service) was 139,076. The ratio of admissions to hospital was 757·4 per 1000, the constantly sick 37·7, and the deaths and invaliding 8·97 and 24·5 per 1000 respectively. All these ratios, except that for invaliding, were higher than in the previous year, and all were very considerably in excess over the quinquennial averages for 1910–1914, when the admissions averaged 546·9, the constantly sick 20·7, the deaths 4·39, and the invaliding 5·39 per 1000. There was a notably increased prevalence of malaria, venereal disease, dysentery, and pneumonia. For malaria the admission and death-rates were 200·7 and 0·69 per 1000 respectively; at Miranshah the admissions were as high as 1710·9 per 1000, the cases being mostly of the malignant tertian type. There was, however, much less pyrexia of uncertain origin (12·4 admissions per 1000, compared with 22·3 in 1915), and sand-fly fever (6·8, compared with 13·9). There were 86 cases of plague, 38 being fatal, the ratios per 1000 being 0·6 and 0·27 respectively; small outbreaks occurred at Poona (11·2 per 1000), and at Pindi (7·3 per 1000), the death ratios being 3·50 and 3·80 respectively. The most fatal disease attacking Indian troops was, as usual, pneumonia (16·9 admissions and 3·35 deaths per 1000); in the Peshawar Division these ratios were 23·7 and 5·57, both much in excess over recent years. Pulmonary tubercle caused 2·8 admissions, and 0·42 deaths per 1000, being most prevalent in the Gurkha regiments, where the admissions were 4·2 per 1000.

Health of the General Population.

The dry weather of the first four months of 1916 affected the wheat crops, especially in the unirrigated areas of the west and north-west; but the rice crops were the highest on record. A further decline in the birth-rate (37·13 per 1000, compared with 38·87 for the preceding quinquennium) applies to the greater part of the country, but not to Madras Presidency, the Punjab, or Lower Burma. The total death-rate of 29·10 per 1000 is slightly lower than that of the preceding quinquennium (30·08). Considerably more than half the deaths (17·13 per 1000) are returned under the head of "fevers," a very vague term. The highest mortality ratio occurred in the Central Provinces and Berar (39·95), the lowest (21·90) in Madras Presidency. Cholera prevailed in the Central Provinces (2 82 deaths per 1000), Bihar and Orissa (2·60), and Assam (2·16); for the whole country the death ratio was 1·21 per 1000. Plague was most severe in Bombay Presidency (4·06 deaths per 1000) and in the Central Provinces (2·06). Taking India as a whole, it was a mild plague year.

The jail sickness and mortality ratios (594 admissions to hospital and 19·78 deaths per 1000) were somewhat in excess of the decennial averages of 584·4 and 19·11 (1906–15), and of those for 1915 (586·1 and 18·74 per 1000). There was great variation in the statistics of different jails: in Bengal the admissions to hospital were 1113·3 per 1000, in Madras they were only 262·8, and in Burma 301·0 per 1000. The death-rates also varied greatly between 60·72 in the North-West Frontier jails and 13·18 in Madras. In Assam jails the improvement has been most marked; for the decade 1906–15 the mortality had averaged 36·87 per 1000; in 1916 it was only 18·97. Sanitary improvements are in progress at Delhi, now the capital of India, and the municipal boundaries of the city have been extended. Pathological and research work in various directions is carried out at the Central Research Institute and at the various Pasteur Institutes, the King Institute, Madras, and the Bombay Bacteriological Laboratory.

This valuable report is submitted by Major F. Norman White, C.I.E., I.M.S., Officiating Sanitary Commissioner with the Government of India, who succeeded Major W. W. Clemesha, I.M.S., in 1917.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Coming Congress of Surgery.

THE Twenty-seventh French Congress of Surgery will meet in Paris from Oct. 7th–10th next in the large amphitheatre of the Faculty of Medicine. Three subjects appear on the agenda, but on this occasion without preliminary abstract—viz.: (1) extraction of intrathoracic projectiles; (2) treatment and remote results of gunshot lesions of the nerves by projectiles; (3) esquillectomy and repair of bony loss.

Serum-therapy of Gas Gangrene.

At the same time that Professor Vincent acquainted the Academy of Science with his discovery of a new preventive serum for gas gangrene the Society of Surgery took a keen interest in the question and several communications were made to it upon the subject. M. P. Duval and M. Vaucher employed at one and the same time on a series of patients three serums, prepared from the bacterial agents commonly met with in this deadly complication—viz., *B. perfringens*, *B. œdematiens*, and the septic vibrio. The serums were prepared at the Pasteur Institute by M. Weinberg and M. Séguin. The injections were first made in the case of 50 men whose wounds seemed most likely to incur the danger of gangrene, and were administered on an average 5–6 hours after receipt of the wound, occasionally 10, 12, or even 18 hours after. None of these cases contracted gas gangrene; 25 died in the first 24 hours owing to the severity of the injury, but without sign of gangrene. None of those who recovered had symptoms of gangrene. After the battle of Flanders 37 men were treated in similar wise on an average 16 hours after being wounded. The three serums were injected at the same time in equal doses of 10–30 c.cm. A first group of 21, whose wounds, though grave, were in good condition, recovered without incident. Another series, who did not arrive at the field hospital until 20 hours after being wounded and whose wounds were already copiously infected, gave the following result: 2 deaths from streptococcal septicæmia without gas gangrene; 4 with wounds in very bad condition in which gas gangrene developed, of which 2 died, and 2 recovered after fresh injections of serum; 2 more seriously wounded and inoperable on arrival who died in spite of large injections. These two authors concluded in favour of the method, used as a complement to surgical operation. Professor Delbet reported on a case of antigangrenous serum-therapy with recovery in the case of a patient reaching hospital with gangrene of 24 hours' duration. He is satisfied that serum-therapy on the lines described is a most effective measure. M. Veau and M. Baudet reported each a similar case. M. Rouvillois has employed serums prepared from *B. bellonensis* and the septic vibrio. Among 12 cases of gangrene not treated with serum only one recovery occurred, and that one following operation; 25 other cases were treated with serum, of which 5 died of wounds without evidence of gangrene, while of the remaining 20 14 recovered and 6 died.

Aviators' Heart.

M. G. Etienne and M. Lamy, of Nancy, have systematically examined with the aid of radioscopy the hearts of a series of aviators, finding evidence of the existence of considerable hypertrophy. The hypertrophy sets in early, being demonstrable after five months of flying, and persists even in the case of aviators who had long ceased to fly. Its degree is roughly proportional to the altitude habitually reached. Simple examination on the screen serves to distinguish between chasers and bombers flying at 5000–6000 metres, and pilots and machine-gunners keeping within the 1000–3000 metre limit. The hypertrophy is progressive, beginning with a phase of rapid development, remains of moderate degree, and involves principally the left ventricle. Compensation nearly always remains perfect. The maximum tension is slightly raised in proportion to the increased muscular strength of the heart; the minimum tension remains normal. This cardiac hypertrophy is practically a physiological adaptation brought about by the effort of the heart to adapt itself to circulatory modifications, especially those of vascular pressure, determined by the varying conditions of the atmosphere crossed in flight, and by the incidents of aviation in general.

August 19th.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

SUBSCRIPTIONS TO THE SECOND APPEAL.

THE following subscriptions and donations to the Fund have been received during the week ending August 17th:—

	£	s.	d.
Dr. Alfred Cox (monthly)	1	1	0
Lt.-Col. W. M. Dawson, R.A.M.C.	2	2	0
Dr. S. W. Carruthers ...	1	1	0
Dr. F. S. Palmer	2	2	0
Messrs. Steel Brothers and Co., Ltd.*	105	0	0
Sir James Barr	5	5	0
Staff-Surg. W. Kenneth Wills, R.N.V.R.	5	0	0
Messrs. Burroughs Wellcome and Co.	100	0	0
Dr. H. E. Belcher	2	2	0
Dr. L. B. Poole	2	2	0
Dr. J. R. Keith	1	0	0
Capt. H. E. H. Oakeley, S.A.M.C.	10	0	0
Capt. R. M. Stewart, R.A.M.C.	1	1	0
Dr. Percy Hughes† ...	3	3	0
Dr. W. H. Rowlands† ...	2	2	0
Dr. C. L. Hawkins† ...	2	2	0
Dr. Ambrose†	2	2	0
Dr. Williams†	1	1	0
Dr. Coaker†	1	0	0
Mr. Beilby†	1	1	0
Small sums†	0	11	0

* Per Dr. Herbert Spencer.

† Collected by Dr. Cameron Kidd.

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W. 1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

A. Patton to be temporary Surgeon.

ROYAL NAVAL MEDICAL RESERVE.

To be temporary Dental Surgeons: J. G. Townsend, W. G. Bowie, G. K. MacLennan.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. W. Bennett to be temporary Colonel whilst employed as Assistant Director of Medical Services of a Division.

Temp. Major A. Chartres to be acting Lieutenant-Colonel while in command of a Medical Unit.

Major J. A. Anderson to be temporary Lieutenant-Colonel whilst specially employed.

Temp. Major A. W. Nuthall (Capt., R.A.M.C. (T.F.)) relinquishes his temporary commission on re-posting.

H. E. Durham to be temporary Major whilst specially employed.

R. S. Turton and T. W. Shaw to be temporary Majors.

Temporary Lieutenants to be temporary Captains: G. A. Ticehurst, H. Holt, J. Raffan.

Late temporary Captains granted the honorary rank of Captain: T. MacHardy, H. W. Ward, J. H. Paterson, L. M. Davies.

To be temporary Captains: A. M. Ross, W. Edgecombe, E. F. Buckler, J. McI. Falkiner, J. B. O. Richards (late Captain, Devon Regt.), Hon. Capt. M. R. MacKay, D. Cotterill, G. Birch, Hon. Capt. V. M. Fisher, O. G. Morgan, J. A. Hadfield, R. L. Moorhead (late Surgeon-Captain, Yeo., T.F.), temp. Lieut. R. A. Attridge.

Temp. Hon. Lieuts. J. F. Harvey and J. V. Ricci to be temporary Honorary Captains.

To be temporary Lieutenants: A. C. Brown, W. N. Leak, C. J. L. Palmer, C. V. Macnamara, R. Price, J. Butterworth, J. Paxton, E. H. Milson, O. H. Woodcock, P. C. MacRobert, J. Clarke, J. Good, Z. M. H. Ross, T. S. Macaulay, J. M. Reid, G. H. Dunn, J. C. Carr, F. McF. Fellows, G. Smith, H. S. Roberts, C. M. Smith, W. G. MacArthur, V. D. Pennefather, I. Clarke, L. P. MacK. Gardner, N. B. Benjafield, A. G. L. Smith, R. M. Rendall, J. McClellan, B. D. Merrin, J. L. Phibbs, J. A. Aitken, B. Blacklock, A. P. Mitchell, R. Clark, G. H. Dart, O. Marriott, S. McClure, J. C. Warrick, G. B. Woodroffe, A. E. Hodgkins, H. P. Fairlie, R. W. Gilmour.

S. A. Moor to be temporary Honorary Lieutenant.

V. P. G. Pedrick, late temporary Lieutenant, to be honorary Lieutenant.

Temp. Lieut.-Col. R. B. Graham (Lieut.-Col., ret., T.F.) relinquishes his temporary commission.

Officers relinquishing their commissions: Temp. Majors H. C. T. Langdon and S. R Scott. Temp. Capts. H. J. Norman, A. McP. Warner, W. Clow (on appointment under the Ministry of National Service), A. Paterson, W. J. Macdonald, H. F. MacKendrick, O. De Muth, J. B. Anderson, H. G. Coulthard, T. H. Crews, S. Waddell, R. R. Scott, E. H. Lawson, S. H. Calnek, C. G. Sutherland, H. B. Lawson, A. M. Cowie, G. M. DeVine, D. S. Page (on account of ill-health and are granted honorary rank of Captain), W. C. Mayo, R. H. Dix and R. P. Kennedy (on account of ill-health contracted on active service and are granted the honorary rank of Captain), J. Mitchell (on account of ill-health caused by wounds received in action). Temp. Lieuts. R. J. Archibald and W. M. Hume (on account of ill-health and are granted the honorary rank of Lieutenant), and G. S. Ewen.

SPECIAL RESERVE OF OFFICERS.

Lieutenants to be Captains: C. C. Chesterman, J. C. Collins, W. I. FitzG. Powell, C. G. Irwin, J. B. S. Lewis, T. H. McLeod, A. G. E. Wilcock, C. V. Pink, H. W. Leatham, W. G. Woolrich, C. K. Mowll, H. J. C. Churchill, A. O. Bolton, D. Cameron, A. Rose-Innes, J. P. Williams, J. Rowland, H. Gainsborough, R. S. Corbett, I. Braun, R. L. Robinson, J. H. Wiseman, H. G. V. Mence, T. W. Shaw, J. W. Bowman, C. A. Harvey, J. Irvine, J. Kinnear, F. J. Charlton.

Capt. M. W. H. Miles relinquishes his commission on account of ill-health and is granted the honorary rank of Lieutenant.

M. Jackson and G. P. W. Staunton (from University of London Contingent, O.T.C.) to be Lieutenants

D. O. Macdonald to be Lieutenant.

TERRITORIAL FORCE.

Temp. Hon. Lieut.-Col. E. W. White to be temporary Lieutenant-Colonel.

Major E. J. Maclean to be acting Lieutenant-Colonel whilst specially employed.

Major A. F. Fergus relinquishes his commission on account of ill-health and is granted the honorary rank of Major.

Capt. G. M. A. Thomas relinquishes his commission on account of ill-health and is granted the honorary rank of Captain.

Capts. L. A. Avery and R. Thornton to be Majors.

Capt. (Brevet-Major) C. H. S. Frankau is seconded whilst holding a temporary commission in the R.A.M.C.

Capt. W. A. Phillipps relinquishes his commission on account of ill-health and is granted the honorary rank of Captain.

Capt. W. C. Hodges to be acting Major whilst specially employed.

Capt. (acting Major) L. Milton relinquishes his acting rank on ceasing to be specially employed.

L. F. Wallis, A. R. Ward, A. W. Bartlett, E. Jones, and F. Rae, to be Lieutenants.

Temporary Captains relinquishing their commissions: F. N. B. Smartt, J. Tichborne, R. J. Morgan, H. Whitwell, and P. S. MacLaren, who is granted the honorary rank of Captain.

Temp. Lieut. F. H. R. Heath relinquishes his commission.

Lieut. J. Jackson to be Captain.

Attached to Units other than Medical Units.—Capt. J. D. Wells to be a Deputy Assistant Director of Medical Services, and to be acting Major whilst so employed.

ROYAL AIR FORCE: *Medical Branch.*

H. J. Leviseur (late temp. Surgeon, R.N.), C. L. Birmingham (late temp. Lieutenant, R.A.M.C.), H. L. H. Greer (late Captain, R.A.M.C.) are granted temporary commissions as Captains.

The undermentioned are granted temporary commissions as Lieutenants: N. Homewood, R. G. J. McCullagh, S. A. Nield-Faulkner, P. C. Parr, N. Rumboll, G. Meadows, T. Montgomery, V. A. Spong.

INDIAN MEDICAL SERVICE.

Col. C. R. M. Green has been appointed to succeed Col. Robinson as Inspector-General of Civil Hospitals in the Central Provinces.

Lieut.-Col. A. D. Jameson, R A.M.C., has been appointed to succeed Major F. W. W. Dawson, R.A.M.C., Commandant of the Rangoon Station Hospital, who has left Rangoon on transfer in command of a hospital ship.

Major N. Walker, Professor of Medicine at the King George's Medical College, Lucknow, has been posted to Mussoorie as Civil Surgeon; Major J. W. D. Megaw, the Principal of the College, will act as Professor of Medicine in addition to his other duties.

Major R. A. Needham has been appointed Assistant Director-General (Sanitary) at Headquarters, and Major H. Ross succeeds him as Assistant Director-General (Stores).

Lieut.-Col. S. C. Evans has been appointed to act as Principal, Grant Medical College, in addition to his own duties.

URBAN VITAL STATISTICS.

(Week ended August 17th, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had steadily declined from 21·1 to 10·4 in the five preceding weeks, was again 10·4 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 9·8, or 0·7 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 4·9 in Carlisle, 5·0 in Wallasey, and 5·1 in Hornsey, to 17·3 in St. Helens, 18·5 in West Hartlepool, and 25·0 in Barnsley. The principal epidemic diseases caused 289 deaths, which corresponded to an annual rate of 0·9 per 1000, and included 168 from infantile diarrhœa, 39 each from measles and whooping-cough, 31 from diphtheria, 8 from scarlet fever, and 4 from enteric fever. During the past five weeks the deaths from

diarrhœa have shown a progressive increase, but were below the numbers recorded in the corresponding period of last year. The 739 cases of scarlet fever and 903 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 7 and 1 below the respective numbers remaining at the end of the previous week. Of the total deaths in the 96 towns 116 resulted from violence. The causes of 33 deaths were uncertified, of which 8 were registered in Liverpool and 5 in Birmingham.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 10·0, against 13·1 and 11·8 per 1000 in the two preceding weeks. The 233 deaths in Glasgow corresponded to an annual rate of 10·9 per 1000, and included 27 from infantile diarrhœa, 6 from whooping-cough, and 3 from diphtheria. The 51 deaths in Edinburgh were equal to a rate of 8·0 per 1000, and included a fatal case each of whooping-cough and diphtheria.

Irish Towns.—The 135 deaths in Dublin corresponded to an annual rate of 17·6, or 2·3 per 1000 above that recorded in the previous week, and included 22 from infantile diarrhœa, 2 from whooping-cough, and 1 from enteric fever. The 118 deaths in Belfast were equal to a rate of 15·7 per 1000, and included 13 from infantile diarrhœa, and 1 each from enteric fever and whooping-cough.

VITAL STATISTICS OF LONDON DURING JULY, 1918.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 3·5 per 1000 of the population, estimated at 4,026,901 persons; in the three preceding months the rates had been 3·9, 4·1, and 4·5 per 1000. The lowest rates in July were recorded in Chelsea, the City of Westminster, Hampstead, Islington, Stoke Newington, Holborn, and Wandsworth; and the highest rates in Shoreditch, Bethnal Green, Stepney, Southwark, Bermondsey, and Greenwich. One case of small-pox was notified during the month, against 5, 21, 4, 3, and 0 in the five preceding months; this case belonged to Islington. The prevalence of scarlet fever was about 15 per cent. less than in the preceding month; this disease was proportionally most prevalent in Kensington, Finsbury, Shoreditch, Southwark, and Deptford. The Metropolitan Asylums Hospitals contained 753 scarlet fever patients at the end of the month, against 898, 786, and 846 at the end of the three preceding months; the weekly admissions averaged 105, against 105, 129, and 127 in the three preceding months. The prevalence of diphtheria was about 25 per cent. less than in the preceding month; the greatest proportional prevalence of this disease was recorded in the City of London, Shoreditch, Bethnal Green, Stepney, Southwark, Bermondsey, and Greenwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1358, 1232, and 1179 at the end of the three preceding months, numbered 918 at the end of July; the weekly admissions averaged 122, against 143, 202, and 165 in the three preceding months. The prevalence of enteric fever was slightly less than in the preceding month; of the 35 cases notified in July, 4 belonged to Hammersmith, 4 to Fulham, 3 to St. Marylebone, 3 to Hackney, and 3 to Lambeth. There were 23 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 23, 32, and 40 at the end of the three preceding months; the weekly admissions averaged 4, against 3, 5, and 6 in the three preceding months. Erysipelas was proportionally most prevalent in St. Marylebone, Shoreditch, Bethnal Green, Poplar, Southwark, and Camberwell. The 12 cases of puerperal fever included 5 in Lambeth. Of the 18 cases of cerebro-spinal meningitis 3 belonged to Battersea, 2 to Poplar, and 2 to Wandsworth; while of the 7 cases of poliomyelitis 2 belonged to St. Marylebone and 2 to Bermondsey.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the five weeks ended August 3rd the deaths of 5724 London residents were registered, equal to an annual rate of 14·8 per 1000; in the three preceding months the rates had been 17·1, 13·7, and 11·8 per 1000. The death-rates ranged in July from 9·9 in Wandsworth, 10·0 in Lewisham, 10·8 in Hampstead, 11·6 in the City of London, 12·0 in Kensington, and 12·1 in Paddington, to 18·0 in Greenwich, 18·6 in Finsbury, 19·1 in Bethnal Green, 19·9 in Bermondsey, 20·4 in Holborn, and 21·4 in Southwark. The 5724 deaths from all causes included 376 which were referred to the principal infectious diseases; of these, 139 resulted from measles, 13 from scarlet fever, 48 from diphtheria, 129 from whooping-cough, 4 from enteric fever, and 43 from diarrhœa and enteritis among children under 2 years of age. No death from any of these diseases was recorded during the month in the City of London. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in Kensington, Hammersmith, Deptford, and Lewisham; and the highest in Finsbury, Bethnal Green, Southwark, Bermondsey, Lambeth, and Greenwich. The 139 deaths from measles were 34 above the average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in Fulham, St. Pancras, Bethnal Green, Southwark, Bermondsey, Lambeth, and Greenwich. The 13 fatal cases of scarlet fever were 4 below the average number, and included 4 in Lambeth, 2 in Kensington, and 2 in Southwark. The 48 deaths from diphtheria exceeded the average number by 2, and included 6 in Stepney, 5 in Islington, 4 in St. Pancras, 4 in Lambeth, 4 in Camberwell, and 3 in Hackney. With the exception of the preceding month, the mortality from whooping-cough was considerably lower than in any other month of the year, the deaths numbering 129 against an average of 58; this disease was proportionally most fatal in Paddington, Fulham, Finsbury, and Southwark. The 4 deaths from enteric fever were 6 less than the average; of these 2 belonged to Camberwell. The 43 fatal cases of diarrhœa and enteritis among children under 2 years of age were less than a third of the average; 5 deaths belonged to Bermondsey, 4 to Islington, and 3 each to Kensington, Southwark, Wandsworth, Camberwell, Greenwich, and Woolwich. In conclusion, it may be stated that the aggregate mortality in London in July from these principal infectious diseases was 3 per cent. below the average.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JULY, 1918.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated civil population, 1917.	Notified Cases of Infectious Disease.											Deaths from Principal Infectious Diseases.								Deaths from all causes.	Death-rate per 1000 living.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cerebro-spinal meningitis.	Poliomyelitis.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping-cough.	Enteric fever.	Diarrhœa and enteritis (under 2 years).	Total. "Audi alteram partem."

THE FUTURE OF THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—I am not sure that it is worth while my discussing with Mr. Charles Parker what was the exact position of "the extreme Left party" in medical politics a few years ago. We may take it, however, that Mr. Parker, as an officer of the State Medical Service Association, is an authority on the present position of the party, and I am bound to say that its position, as stated in his letter to you last week, seems less logical and less practical than that which I assigned to it in my recent address on Medicine and the State. In pleading for more satisfactory relations between general practitioners and consultants I pointed out that "competition and coöperation cannot go hand in hand." Mr. Parker seizes on this phrase, states that it expresses a truism of universal application, and claims as a chief advantage of his party's ideals that they will completely abolish competition. But surely if it is now proposed to allow each medical man upon qualification to choose between becoming a whole-time servant of the State or a private practitioner, there will indeed be introduced between these two sections of the profession a very fierce form of competition. How otherwise indeed than by competition to the uttermost is Mr. Parker's belief "that private practice would then die a natural death" to be fulfilled? So long as man is allowed to be possessed of private property and to have any option in its disposal, large numbers of individuals will undoubtedly desire to make use of their wealth in order to purchase the private advice of such medical men as are allowed to compete for practice with the State Medical Service. If the extreme Left party desires to eliminate this form of competition it will be necessary to absorb into the State service every practitioner as and when he is qualified and to protect the service by making it illegal for any other persons to practise medicine.

The policy of the "extreme Left party," as re-stated by Dr. Benjamin Moore and Mr. Parker, is to abolish competition, and they believe that a whole-time salaried service will secure this. But will it? Does it do so in other whole-time salaried services? Is there not competition for more honourable or better paid whole-time jobs? Might there not be competition for less responsibility and lighter work? Might not a salaried doctor by cultivating the smiles of his Administrative Board instead of his patients compete with his fellows for early promotion? Might he not by want of sympathy and indifference to his troublesome patients and by constant reference to a higher authority compete with his more conscientious colleagues for ampler leisure to devote to scientific research or even to recreation? Elimination of competition is a party shibboleth, which, human nature being what it is, is not within our capacity to attain. In our present attempt to reconstruct medicine we shall be seriously handicapped if we follow any such will-o'-the-wisp. Let us by all means endeavour to eliminate obviously evil forms of competition such as underselling, profiteering, and qualified quackery, but let us recognise that amongst the most honest and honourable men there must always exist varying powers which may justifiably be used to increase one's opportunity of useful service.

My contention that coöperation and competition cannot go hand in hand as the basis of the relationship between consultants and general practitioners is founded on actual experience of everyday conditions. Few general practitioners will deny that they are constrained from seeking specialist advice for their patients, on every occasion when they would value it, by the fact that most specialists undertake independent, as well as consultative, practice, and thereby place themselves in competition with general practitioners. Few specialists will deny that they would prefer always to act in coöperation with a general practitioner, if by so doing their professional time were sufficiently occupied and an adequate income could be earned. To admit that a mixture of coöperation and competition between these two sections of the profession does not make for the public good, and to urge that in any scheme of reconstruction an attempt should be made to eliminate the competition, is not the same thing as asserting that all professional competition is undesirable. The belief that by proper organisation competition between consultants and general practitioners could be eliminated does not commit one to the proposition that in our present stage of civilisation the total abolition of competition is praticable. Even if total abolition of competition were practicable and desirable a whole-time salaried service would not secure it.

I am, Sir, yours faithfully,

August 11th, 1918. LAURISTON E. SHAW.

40 D.

To the Editor of THE LANCET.

SIR,—The powerful leading article which you publish in your number of August 17th on the subject of 40 D must convince everyone that the maintenance of the law as it at present stands is undesirable. It does not therefore follow that no attempt should be made to attain the object of 40 D by other means; indeed, such an attempt appears imperative in the interest of public health. May I suggest an alternative?

You state that some clinicians go so far as to regard the cure of gonorrhœa in the female as impossible and that the difficulty of a cure is admitted by all. Surely, this leads to the conclusion that we must aim at prevention and not cure. At the present moment facilities for prophylaxis are established for soldiers and very large sections of the male population, and these have diminished in a greater or lesser degree the danger of infection, but in the case of women such facilities either do not exist or are not availed of to any material extent. Are not women entitled to at least equal facilities for the prevention of infection? Indeed, arguing the matter from the national health standpoint, it would be easy to contend that facilities for them should not be equal but greater, as cure in their case is infinitely more difficult, while the presence of disease constitutes among certain classes an infinitely greater danger to the community. It is no argument against this procedure to say that its success will render promiscuous intercourse less dangerous for men, for this result would occur in all events which improve the general exemption from disease.

The main cause of failure, up to recent years, of all attempts to solve the drink problem was the fact that reformers mixed up physiology and morality, and judged physiological measures in the coloured light of their supposed moral effect. Let us not make the same mistake in the case of the venereal diseases. Morality and physiology have both their claims, but they must be treated separately and not in confused conjunction.

I am, Sir, yours faithfully,

August 20th, 1981. X. Y. Z.

HARVEY AND THE PLACE OF PATHOLOGY IN MEDICINE.

To the Editor of THE LANCET.

SIR,—The present-day inadequate instruction in pathology would have been criticised by Harvey. In the first of his Anatomical Exercitations concerning the Circulation of the Blood Harvey says:—

> "And I dare say the opening and dissection of one consumptive person, or of a body spent with some ancient or venomous disease, has more enriched the knowledge of physick than the dissections of ten bodies of men that have been hanged."

This dictum of Harvey, which might well serve for the text of a Harveian orator, has not, so far as I know, received the attention which it deserves. It occurs in a letter to John Riolan, professor and dean of anatomy in the University of Paris, expressing the desire which the publication of Riolan's "Encheiridion" had excited in Harvey to put forth a work on medicinal anatomy similar to Riolan's "Treaties concerning Anatomy and Diseases." Amongst other things, Harvey says, in close connexion with this, that "from pathology the use and art of administering physick, and occasions of inventing many new remedies do occur."

It is clear even at this time, in about 1650, that the man whom Harvey calls "the Prince of Dissectors of Bodies," and the discoverer of the circulation of the blood were at one as to the importance of pathology to the practitioner of

medicine, without depreciating the necessity of a knowledge of anatomy and physiology, but certainly does not place pathology behind them, when he makes this comparison. Indeed, this would seem to be a truism which one would have thought no teacher of any portion of the medical curriculum would have denied, yet it is often denied by the self-styled "pure physician." Even a layman such as Francis Bacon saw this, and in his philosophical work on the Advancement of Science (Bk. II., X. 5) he says:—

"In the enquiry which is made by anatomy (that is, by post-mortem examination), I find much deficience: for they enquire of the parts and their substances, figures, and collocations; but they enquire not of the diversities of the parts, of the secrecies of the passages and the seat or nestling of the humours, nor much of the footsteps and impressions of diseases. And for the humours, they are commonly passed over in anatomies as purgaments, whereas it is most necessary to observe what cavities, nests, and receptacles the humours do find in the parts with the differing kind of humour so lodged and received. And as for the footsteps of diseases.....they ought to have been exactly observed by a multitude of anatomies and the contribution of men's several experiences. ..... I will not doubt to note as a deficience that they enquire not the perfect cures of many diseases, or extremities of diseases, but pronouncing them incurable do enact a law of neglect, and exempt ignorance from discredit."

These words of Bacon apply especially to the so-called practical pathology as taught nowadays, in which considerable attention is paid to staining methods and the examination of microscopic sections, while true experimental pathology is hardly taught at all. In fact, I doubt whether there are any teachers of pathology who are aware of the possibilities of instructing the student in experimental pathology by the use of decerebrate animals. To those unaware I would suggest that they should study the course of experimental physiology as carried out in the University of Oxford, and would counsel them to adapt it to the course of experimental pathology.

But even at the present time there are several learned institutions in which the time devoted to the teaching of pathology is hopelessly insufficient, and proposals for its increase meet with opposition, and consideration of the matter is deferred for the duration of the war, as if the war could make any difference as to the amount of teaching required in any particular subject. One might as well defer all alterations in teaching until the war is over on this line of argument. That would be recognised as an obviously silly proposition, yet the other is on a level with it.

Some years ago I took the trouble to inquire of various universities the amount of time which was devoted to the teaching of this subject. The result obtained was approximately as follows:—

Leeds	120 hours.	Cambridge ...	200 hours.†
Liverpool	140 ,,	Birmingham ...	220 ,,
Guy's Hospital	160* ,,	Oxford	250 ,, about.
Manchester	170 ,,	Edinburgh ...	300‡ ,, ,,
Glasgow...	180 ,,		

* Plus extra for University candidates. † For Part I. pathology only.
‡ Two hours daily during three terms.

It was difficult to ascertain the amount of time spent in the dead-house, and it seemed occasionally not to be actually, even if it was nominally, compulsory.

In other medical subjects at Leeds (I quote Leeds as being the University with which I am best acquainted):—

Physiology ...	310 hours.	Surgery*	900 hours.
Anatomy	800 ,, about.	Gynæcology*	450 ,,
Medicine*... ...	900 ,,	P.M.	50 ,,

* Exclusive of school lectures.

Roughly, the estimation in which the degrees of these bodies are held may be said to be in proportion to the time spent on pathology.

In estimating the value of Harvey's opinion in this matter it is to be remembered that he was professor of anatomy and surgery at the Royal College of Physicians and also physician to the King, and consequently of considerable clinical experience and practice. Conversely, many physicians of repute have also been expert pathologists—for instance, Addison, Bright, Moxon, Goodhart, Bristowe, and many others.

If we regard, as Harvey also does, physiology as the science of health and pathology as the science of disease, there does not appear to be any reason why more time should be devoted to the former than to the latter in the medical curriculum. Nor is there any reason why the *art* of medicine should receive such a comparatively excessive amount. I mean by that excessive beyond the *science* of disease; it is not excessive for what is required, as seen by the above table. Inasmuch as pathology covers a similar area of knowledge as physiology or anatomy, there is no ground for supposing that the acquisition of this necessary knowledge would take less time in one case than in the other.

I plead, then, for more extended teaching of the subject which Harvey calls "the doctrine of diseases" (i.e., pathology) "by which actions of the body are hurt." "In this range sickness and its causes and accidents are handled, but the physician performeth his cure by preserving health and restoring it (if it so please God) when it is lost."

I am, Sir, yours faithfully,

August 10th, 1918. A. S. LEYTON.

WAR DEAFNESS.

To the Editor of THE LANCET.

SIR,—In your last issue Major Hurst, R.A.M.C., has criticised the article by Dr. Logan Turner and myself on "War Deafness." Nothing would please me more than to find that we have been unduly pessimistic, but, on the other hand, nothing adduced by Major Hurst has in the smallest degree affected my belief in the accuracy of the conclusions we have arrived at by clinical study of a large number of cases.

Major Hurst says, "My own 'opportunities of studying ear diseases' before the war were fortunately nil, and I was therefore able to face the problem of war deafness with an unprejudiced mind." Now from his letter I much fear that he has not studied the question from a scientific point of view even now, and that, as a consequence, his mind has remained not only unprejudiced but uninformed. To be perfectly candid, it occurred to me on first reading his letter that it required no reply, because it consisted of statements resting not upon the production of a definite series of properly observed cases but upon an *ipse dixit* and a certain number of inaccuracies. On consideration, however, it suggested itself to me that some of your readers might not compare our original paper with Major Hurst's letter, and might in consequence be influenced by the views he has expressed, so for this reason it has seemed necessary to reply.

To put the matter briefly, general statements are not of the slightest value in a controversy of this kind, and unless Major Hurst is able to produce a series of cases in support of his views these views will remain valueless. If and when he does so we shall all no doubt be prepared to give them the attention they deserve.

If he will consult otological literature Major Hurst will be able to convince himself of the fallacy of his statement that "it is very unlikely that the cochlea should be so damaged that complete deafness results without the adjacent semicircular canals being affected." I fear that his criticism of our two cases in which he has arrived at a diagnosis of hysterical deafness is rather characteristic of his methods. In one of them the injury which produced the deafness (Case 1, Group D) caused perforation of the tympanic membrane as well as a concussion lesion of the cochlear apparatus. Does he then think that the objectively demonstrable middle-ear suppuration was also hysterical, and if not, why not? Of course, I do not deny that hysterical deafness may occur in soldiers who have been exposed to shelling, only I believe it to be rare, and I hold that the cases recorded by Dr. Logan Turner and myself have proved that vestibular tests are not of great value in diagnosing between functional and organic deafness.

I am, Sir, yours faithfully,

Edinburgh, August 18th, 1918. P. MCBRIDE.

THE DISAPPOINTMENTS OF VACCINE THERAPY.

To the Editor of THE LANCET.

SIR,—I have read without surprise Dr. H. G. Adamson's paper with the above title in your issue of August 10th. His disappointment in the therapeutic results of vaccine therapy is, from the quotations he gives, evidently shared by Sir Almroth Wright, and, indeed, is general amongst those who follow the orthodox method of administration.

I have frequently pointed out during the last 13 years the common causes of failure. Let me repeat them:—

1. Inadequate dosage.
2. The use of the wrong or bad antigen.
3. Bad spacing of the doses.
4. Very rarely, incapacity of the patient to react.

Dr. Adamson says he rarely cures a case of sycosis barbæ or of acne vulgaris. I very rarely fail to do so. I may say the same of gonorrhœa, gleet, and lupus. These last three are practically always mixed infections, so that a single antigen is not likely to succeed. I have had the most rapid and dramatic results in two cases of paratyphoid B and three of *B. typhosus* infection, but again not with the specific antigen alone; it is necessary to include the patient's *B. coli* as well.

As to the dangers of abnormal reaction they are chimerical, as they can be controlled by the exhibition of iodine.

I ask Dr. Adamson to read my book "Therapeutic Immunisation" and to try again. I shall be much surprised if he does not get greatly improved results. I always feel myself that if I fail it is generally my own fault, that I have missed some essential microbe or that I have failed to adapt my immunisation to the reactivity of the patient. I am not so foolish as to think that the use of vaccines precludes the use of other methods of treatment, on the contrary; but I know that by its means results can be attained which can be obtained by no other known method.

I am, Sir, yours faithfully,

University College, Dublin, August 17th, 1918. W. M. CROFTON.

TRANSIENT HEMIPLEGIA.

To the Editor of THE LANCET.

SIR,—Enjoying a brief holiday, I have only just read the clinical note and your annotation upon my case of transient hemiplegia. The cerebro-spinal fluid was not examined, as owing to the rapid recovery of the patient to a condition of good health one did not feel justified in pursuing a very active investigation. There are none of the usual evidences of arterio-sclerosis, although an interesting cardiac condition was verified by autopsy in the patient's father, who died at a comparatively early age.

If I may say so, this case illustrates fully the need of a better coördination of work, happily called "team-work" by Sir Bertrand Dawson in his recent and most opportune manifesto. Many of his suggestions were published in the memorandum of the London Local Medical and Panel Committee in June, 1917. Those ideas were dominant in the minds of those who, in 1912, urged the profession to accept the modified terms of the National Insurance Act as a first great instalment of State coöperation, as applied to civilian medical services. The principle of mutual aid which the words "team-work" so happily express seems to me the only hope for both humanity and civilisation.

I am, Sir, yours faithfully,

Studland, Dorset, August 20th, 1908. H. H. MILLS.

A NEW REFLEX SIGN IN SPASTIC PARAPLEGIA.

To the Editor of THE LANCET.

SIR,—In THE LANCET of June 1st last, on p. 777, there appeared an editorial note under the above heading. The sign has been described recently by Dr. Bing, the neurologist of Basle, and consists of *plantar* flexion of the ankle when the *dorsum* of the foot is struck at any point along an imaginary line between the malleoli. It is stated that the sign occurs constantly in organic spastic conditions of the lower extremities, and that Dr. Bing claims that this "paradoxical" Achilles jerk can be elicited in cases in which the more common reflex signs of spasticity from cortico-spinal impairment appear to be absent.

Since June 1st I have made a point of testing this sign in every one of a large number of patients and I have found that, whereas it is certainly present in the conditions mentioned above, it is present also in cases of non-organic disease in which the tendon-jerks are exaggerated, and also in a considerable proportion of cases which, to my examination, are neurologically normal.

The matter can readily be tested by everyone for himself, and I think that it will be found that the sign has not quite the significance which has been claimed for it by its distinguished describer and by the author of your note.

I am, Sir, yours faithfully,

HILDRED CARLILL, M.A., M.D., M.R.C.P.,
Neurologist to the Royal Navy; Assistant Physician, Westminster Hospital, &c.

R.N. Hospital, Haslar, August 17th, 1918.

The War.

THE CASUALTY LIST.

THE following medical officers appear among the casualties announced since our last issue:—

Killed.

Capt. W. H. Lister, D.S.O., M.C., with bars, R.A.M.C., was a student at University College, London, and qualified in 1913. At the time of the outbreak of war he was holding an appointment at University College, which he at once resigned, and joined up. He saw service in France and in Italy, in which latter country he was killed. In the Balkan War he served as a dresser in the British Red Cross Unit with the Greek army, for which he was awarded the Balkan Medal. The awards of the D.S.O., the M.C., and bars were recorded in THE LANCET respectively of June 26th, 1915, p. 1373; Oct. 28th, 1916, p. 770; Dec. 2nd, 1916, p. 595; and Dec. 22nd, 1917, p. 951.

Capt. G. H. H. Almond, R.A.M.C., received his education at Loretto, at Oxford, and at St. Bartholomew's Hospital, London, and qualified in 1906. After holding appointments at St. Bartholomew's Hospital and at the West London Hospital, he practised at Bath, where he was honorary assistant pathologist at the Royal United and Mineral Water Hospitals. He served in the South African War in a combatant capacity.

Lieut.-Col. A. J. A. Menzies, D.S.O., R.A.M.C., qualified at Edinburgh in 1912, and joined the R.A.M.C. prior to the outbreak of war. At the time of his death he was in command of a cavalry field ambulance. The award of the D.S.O. was recorded in THE LANCET of Nov. 13th, 1915, p. 1112.

Capt. W. H. Lloyd, R.A.M.C., attached London Regiment, was a student at the Middlesex Hospital, London, and qualified in 1915. He joined up shortly afterwards.

Surg. L. A. Martin, R.N., was a student at University College Hospital, London, and qualified in 1912.

Previously Reported Missing, now believed Killed.

Capt. C. W. Bond, R.A.M.C., was a student at St. Mary's Hospital, Paddington, and qualified in 1901. A few years later he qualified in dentistry from the Royal Dental Hospital, London. He took part in the Boer War.

Died of Wounds.

Capt. R. C. Rogers, R.A.M.C., attached H.A.C., qualified at Edinburgh at the close of the year 1914. He held an appointment at the Royal Infirmary in that city prior to joining up.

Capt. M. A. McKechnie, Canadian A.M.C.

Capt. T. Whitmore, Canadian A.M.C.

Wounded.

Lieut.-Col. D. Donald, Canadian A.M.C.
Major J. Hughston, R.A.M.C.
Capt. I. M. Barrow, Australian A.M.C.
Capt. D. St. C. Campbell, Canadian A.M.C.
Capt. E. A. McCusker, Canadian A.M.C.
Capt. J. D. H. W. Barnett, Canadian A.M.C.
Capt. D. A. Morrison, Canadian A.M.C.
Capt. J. A. C. Scott, M.C., R.A.M.C., attd. Durham L.I.

Wounded and Prisoner in German Hands.

Capt. G. Perkins, R.A.M.C.

Previously reported Killed, now reported Prisoner in German Hands.

Lieut. A. M. Clare, R.A.M.C., attached Durham L.I.

Previously reported Missing, now reported Prisoners in German Hands.

Lieut.-Col. A. C. H. Gray, R.A.M.C.
Capt. R. M. Handfield-Jones, M.C., R.A.M.C.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Second Lieut. J. H. Wybrants, London Regiment, died of wounds, only son of the late Dr. R. B. Wybrants, of Wincanton, Somerset.

Temp. Capt. T. P. Muspratt, M.C., Worcestershire Regiment, died of wounds, second son of Dr. C. D. Muspratt, of Bournemouth.

Lieut. (acting Major) R. H. Collyns, M.E., Royal Engineers, died of wounds, second son of Dr. R. G. Collyns, of Dulverton, Somerset.

Lieut. R. O. C. Macdonald, M.C., R.F.A., accidentally killed whilst flying in England, son of Dr. R. J. J. Macdonald, of Wuchow, China.

Capt. W. B. Young, R.A.F., accidentally killed whilst flying in England, only son of Dr. J. Young, of Earlston, Berwickshire.

T. S. Keith, Cameron Highlanders, killed in action, youngest son of the late Dr. A. D. Keith, of Aboyne, Aberdeenshire.

Surg. L. A. Martin, R.N., accidentally killed at sea, youngest son of Dr. E. F. Martin, of Weston-super-Mare.

Corp. K. A. Clark, killed in action, elder son of the late Dr. A. W. Clark, of Wisbech, Cambs.

Lieut. R. A. Edwards, West Yorkshire Regiment, died of wounds, youngest son of Lieut. E. H. Edwards, R.A.M.C., of Rochdale, and formerly of Tai Yüan Fu, China.

Capt. O. Horsley, M.C. and bar, Gordon Highlanders, attached R.F.C., killed whilst flying in England, youngest son of the late Sir Victor Horsley, of Cavendish-square, London.

THE HONOURS LIST.

The following are the statements of service for which the decorations recorded in THE LANCET of March 9th, 1918, p. 386, were conferred :—

Bar to the Military Cross.

Temp. Capt. GEORGE LESTOCK THORNTON, M.C., R.A.M.C.—For conspicuous gallantry and devotion to duty. After his two orderlies had been killed he continued to attend to the wounded with complete disregard for his personal safety.

Military Cross.

Temp. Capt. ROBERT DANIELS BELL, R.A.M.C.—For conspicuous gallantry and devotion to duty. On the battery positions being heavily shelled with gas shells one shell struck a dug-out occupied by three men, badly wounding two of them and gassing the third. This officer immediately proceeded to their assistance, extricated them from the débris, and proceeded to bind up their wounds, removing his own gas mask in order to see more clearly. The men were successfully evacuated to a dressing station, but he, unable to find his mask, became badly gassed. Despite this he persisted in carrying out his duties for some time until he had to be evacuated. His absolute lack of fear was undoubtedly the means of saving the lives of the three men.

BROUGHT TO NOTICE.

The names of the following medical officers have been brought to the notice of the Secretary of State for War for valuable services rendered in connexion with the war :—

Army Medical Service.—Surg.-Gen. W. S. M. Price.

Royal Army Medical Corps.—Lt.-Col. H. J. Barnes, R.P. (late R.A.M.C.); Temp. Capt. D. J. Bedford; Lt.-Col. U. J. Bourke; Temp. Capt. A. E. Boycott; Temp. Maj. F. S. Brereton; Temp. Capt. R. Bruce-Low; Capt. G. A. Child (T.F.); Temp. Capt. W. A. Clayton; Temp. Capt. F. Corner; Temp. Maj. W. B. Cosens; Temp. Capt. S. E. Denyer, C.M.G.; Temp. Capt. J. Fairley; Capt. R. A. Freeman (T.F.); Temp. Lt.-Col. H. French; Lt.-Col. (temp. Col.) C. T. Green, T.D. (T.F.); Capt. L. C. Hayes; Temp. Hon. Maj. T. G. Hine; Capt. (temp. Lt.-Col.) E. A. Houchin (T.F.); Maj. H. A. Howes (T.F.); Temp. Maj. G. P. Humphrey; Capt. (acting Maj.) A. Jackson; Maj.-Gen. O. R. A. Julian, C.B., C.M.G. (formerly R.A.M.C.); Capt. G. E. Kinnersley; Capt. W. P. MacArthur, D.S.O.; Temp. Capt. E. F. W. Mackenzie, M.C.; Temp. Capt. D. W. Maclagan; Temp. Capt. J. A. Marsden; Capt. (local Maj.) A. T. J. McCreery, M.C.; Lt.-Col. H. M. Nicholls; Capt. G. W. S. Paterson; Temp. Capt. R. A. Peters, M.C.; Temp. Capt. (temp. Maj.) H. T. L. Roberts; Temp. Maj. W. V. Robinson; Temp. Capt. T. Russell; Capt. T. Sheedy (S.R.); Lt.-Col. W. F. Somerville, T.D. (T.F.); Maj. C. B. Turner (T.F.); Temp. Maj. R. Wilson; Capt. C. W. Wirgman (T.F.); Temp. Maj. S. W. Woollett; Lt.-Col. J. R. Yourdi, R.P.

Canadian Army Medical Corps.—Maj. S. C. Chown; Lt.-Col. W. H. Delaney; Lt.-Col. P. G. Goldsmith; Capt. (acting Maj.) J. R. Goodall; Lt.-Col. (acting Col.) L. E. W. Irving, D.S.O.; Col. S. H. McKee, C.M.G.; Lt.-Col. K. D. Panton; Capt. E. L. Warner; Capt. C. R. Wilson; Maj. C. A. Young.

Australian Army Medical Corps.—Maj. (temp. Lt.-Col.) J. K. Adey; Lt.-Col. C. E. Dennis; Lt.-Col. W. E. Grigor; Capt. (temp. Maj.) H. O. Lethbridge; Lt.-Col. F. Marshall; Lt.-Col. B. M. Sutherland; Maj. H. H. D. Turnbull; Maj. G. C. Willcocks, M.C.

New Zealand Medical Corps.—Capt. (temp. Maj.) W. Bruce; Capt. D. E. Fenwick; Col. W. H. Parkes, C.M.G.; Maj. T. R. Ritchie; Capt. W. S. Wallis.

South African Army Medical Corps.—Lt.-Col. H. H. Balfour, M.B.E. (temp. Maj., R.A.M.C.); Temp. Maj. J. C. A. Rigby.

United States Medical Corps.—Lt.-Col. W. J. Le H. Lyster.

Jersey Medical Corps.—Maj. A. C. Stamberg (temp. Maj., R.A.M.C.).

Queen Mary's Auxiliary Army Corps.—Dr. A. M. Roberts, Medical Rectg. Controller.

Dr. Mary E. Phillips has been granted permission to wear the Insignia of the Fourth Class of the Order of St. Sava conferred upon her by His Majesty the King of Serbia in recognition of her services with the Scottish Women's Hospitals in Serbia.

THE CHAIR OF SURGERY AT ZURICH.—Professor P. Clairmont, of Vienna, is to succeed Professor F. Sauerbruch as professor of surgery and director of the Surgical Clinic at Zurich.

OBITUARY OF THE WAR.

JOHN DOVER PROUD, M.B., B.S. DURH.,

MILITARY CROSS WITH BAR.
MAJOR, ROYAL ARMY MEDICAL CORPS.

Major J. D. Proud, who died on active service on August 1st, was 26 years of age and the only son of Dr. Frederick Proud, of Maryport. Educated at Charterhouse and Durham University he graduated M.B., B.S. in 1915, and at once joined the R.A.M.C. as a lieutenant in the Special Reserve, from which he later transferred to the Regular Army. Going at once to the Western front he was appointed to a field ambulance attached to a famous Highland division and saw constant fighting for three years. He was awarded the Military Cross in April of last year and a few months later a bar to the cross for conspicuous gallantry and unwearying exertions under heavy fire. He was wounded on July 28th, while acting as bearer officer for the forward clearing of wounded of an infantry brigade, dying at a casualty clearing station four days later.

When a student Major Proud represented his university in all branches of sport, and was a good game shot and keen ornithologist. His colonel writes of him in the field: "He was quite fearless and one of the best officers I have ever had serving under me."

ERIC NEWTON, M.B., CH.B. ABERD.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain E. Newton, who died of wounds in East Africa at the age of 32, had been reported missing since August, 1917, but official intimation of his death was only received recently. He received his early education in India, where his father was a medical officer, continuing at Aberdeen University, and graduating M.B., Ch.B. in 1915. After a brief period as assistant to Dr. A. E. Jones, of Prestwick, he obtained a commission in the R.A.M.C., and was sent out to East Africa in charge of a hospital.

Captain Newton had some reputation as an all-round sportsman. At hockey he was a good full-back, playing on several occasions in international matches, and his quickness and sureness of eye stood him in good stead at lawn tennis and cricket. He was unmarried.

WADE SHENTON GARNETT, M.B., B.S. MELB.,

MAJOR, AUSTRALIAN ARMY MEDICAL CORPS.

Major W. S. Garnett, who was recently killed in France, graduated M.B., B.S. at Melbourne University in 1910 with honours and was appointed to the resident medical staff of the Melbourne Hospital for 12 months. Later on he was resident at the Women's Hospital and at the Children's Hospital, where he became senior resident before commencing practice in Prahran. In April, 1916, he enlisted in the A.I.F., going overseas in August. He was for some months

attached to the staff of an Australian general hospital in France, and later was transferred to a field ambulance and then to the 45th Battalion, with which he was serving when he was wounded fatally by a shell whilst dressing men in the open. His loss is keenly felt amongst a large circle of Australians and others.

WILLIAM McCALL, M.B., C.M. GLASG.,
DISTINGUISHED SERVICE ORDER,
LIEUTENANT-COLONEL, ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel W. McCall, who died in the 1st Southern General Hospital at Birmingham in his forty-seventh year, was the elder surviving son of William McCall, of Irvine, Ayrshire. Educated at the Irvine Royal Academy, where he was a medallist, he went on to Glasgow University, where he graduated M.B., C.M. in 1894. Three years later he settled in Birmingham as assistant in a practice which he eventually bought. In 1908 he joined the R.A.M.C. (T.F.) and was attached to the 1st South Midland Field Ambulance. On the outbreak of war he was mobilised with the Territorial Force and given the rank of major. In March, 1915, he was sent to France, and in 1917 was given command of an ambulance with the rank of lieutenant-colonel. Last November he went with his unit to Italy and was stationed for some time in the neighbourhood of Vicenza, his name being included in the New Year's Honours list. In April he was invalided home and underwent an operation from which he never rallied. He is survived by his widow, a son, and two daughters.

Medical News.

MATRICULATION CANDIDATES FROM THE SERVICES.—Candidates who have been on active service during the present war will be admitted to the matriculation examination by the joint board of the Universities of Manchester, Liverpool, Leeds, Sheffield, and Birmingham under the following conditions: Each candidate will be required to apply to the board on an official form, and to supply evidence of qualifications with a statement of the purpose in joining a faculty of a university. The representatives on the board appointed by each of the universities will conduct an examination to ascertain the general standard attained by the candidate, consisting of a *viva-voce* examination, with a general paper and essay to all candidates, and such other papers as they may think desirable. They have power to exempt from the matriculation examination applicants who satisfy them of their general attainments and ability to take the course in the specified faculty with a reasonable prospect of taking a degree. The fee for examination and for certificate of registration is £2, and forms of application may be obtained from the secretary to the board, 24, Dover-street, Manchester.

CIVICS AND EUGENICS AT OXFORD.—On Monday last, August 19th, a Summer School of Civics and Eugenics was opened at Oxford, with a preparatory course dealing with the scientific basis of educational and social work. The second week, beginning on August 26th, will be divided into three courses, dealing respectively with the training of teachers, social workers, and speakers. Among the lecturers for the various courses and lectures are Professor J. Arthur Thomson, Sir Malcolm Morris, Dr. Mary Scharlieb, Major Leonard Darwin, and Professor James Lindsay. The subjects included in the courses are Venereal Disease, Prostitution, Marriage and Social Welfare, and the Life of Women and Girls in Factories. Further particulars may be obtained from the secretary, Civil and Moral Education League, 11, Tavistock-square, W.C. 1.

ARMY PROHIBITION ORDER IN REGARD TO PHENACETIN AND ACETANILIDE.—In exercising the powers conferred upon them by the Defence of the Realm Regulations Act the Army Council have prohibited the sale or supply of phenacetin and acetanilide, and any salts, preparations, derivatives, or admixtures prepared from or with either of the above-mentioned drugs, to or for any member of His Majesty's Forces except subject to certain conditions. This Order adds two more drugs to a growing list of those forbidden to be sold to the Army. The new Order is dated from the War Office, August 8th, 1918, and appeared in the *London Gazette* of August 13th.

PRESENTATION TO A WOMAN DOCTOR.—Dr. Mary Gordon, who was recently appointed senior medical officer to the Johannesburg General Hospital, was the recipient of an address of congratulation from the Women's Suffrage Conference held at Johannesburg on July 5th. As this is the first appointment of a medical woman made at the institution a similar address was sent to the board of the hospital.

BRITISH DENTISTS' HOSPITAL.—This hospital, founded in 1911, to provide treatment by registered dentists for necessitous workers and their families, has just issued its sixth annual report, dealing with the work at its four centres of Camden-road, Lewisham, Clapham, and St. Pancras School for Mothers. The attendances at these centres during 1917 were 2343, 2566, 880, and 201, a total of 5990. Of these, extraction cases totalled 1804 and fillings 1006, scaling 146, dentures 290, dressings, temporary fillings, and root treatment 412, and crowns 12. The receipts were £539, £674, £256, and £484, and the expenses £728, £610, £367, and £416, showing for the four centres (1) a deficit of £189, (2) a surplus of £64, (3) a deficit of £111, (4) a surplus of £68; or a total net deficit on the working of £168. The constitution and by-laws are under process of revision, as decided by the executive committee in the light of the experience they have gained, and a new scale of fees to be charged for the treatment of patients and supplying dentures has been agreed upon. The President of the hospital is Sir Francis Farmer and the Vice-Presidents include Lady Meyer, the Mayor of St. Pancras, and the medical officers of health for Bermondsey and Tottenham. Mr. George Thomson is chairman of the executive committee and trustee. The head offices are at 31, Camden-road, N.W. 1.

PRESENTATION.—Dr. J. Johnston, the author of "Visits to Walt Whitman," an interesting picture of the American poet in his old age, has been presented with the long-service silver medal of the Order of St. John of Jerusalem in England in recognition of his 27 years' service to the St. John Ambulance Association and Brigade. Dr. Johnston was for 12 years an honorary surgeon to the Bolton Infirmary and for 16 months was an officer on the staff of Queen Mary's Military Hospital at Whalley. He holds the St. John Ambulance South African War medal and the Coronation Medal of King George.

DEATH OF DR. W. R. MACDERMOTT, J.P.—The death occurred at his residence, Poyntzpass, on August 9th, in his seventy-ninth year, of a well-known North of Ireland practitioner, Dr. W. R. MacDermott, who had been medical officer of Poyntzpass Dispensary district, co. Armagh, since 1867. Born in co. Meath, the son of a doctor, Dr. MacDermott graduated in the University of Dublin in 1866, and in the same year he obtained the qualification of the Irish College of Surgeons. In 1868 he was elected medical officer of the Poyntzpass district, the duties of which he discharged to the complete satisfaction of everybody, until in January of this year he was laid aside by illness. At the time of his golden jubilee the guardians granted him a substantial increase of salary, and at the time he died he was the oldest dispensary doctor in Ireland. He was the author of two books, "The Green Republic," dealing with the Irish land question, and "Foughilotra," a story laid in the "montiaghs," or boggy districts along Lough Neagh. He also communicated articles at times to such papers as the *Statist* and *Observer*. In all the relations of life he was kind, sympathetic, and respected by everyone.

BOOKS, ETC., RECEIVED.

ALLEN, GEORGE, AND UNWIN, LIMITED, London.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Avoca, Wicklow.

Births, Marriages, and Deaths.

BIRTHS.

BARRINGTON-WARD.—On August 16th, at George-street, Hanover-square, the wife of L. E. Barrington-Ward, F.R.C.S., of a daughter.
DE BOINVILLE.—On August 18th, at South Grange, Aigburth-road, Liverpool, the wife of Captain V. Chastel de Boinville, M.D., R.A.M.C. (T.), of a son.
CROSBIE.—On August 3rd, the wife of Major D. E. Crosbie, M.C., D.A.D.M.S., of a daughter.
RADFORD.—On August 15th, at Saxtead, Marshall's-road, Sutton, to Muriel Radford, M.B. (née Lloyd), wife of Maitland Radford, M.B.—a daughter.
ROPER.—On August 17th, at Exeter, the wife of Major F. A. Roper, R.A.M.C. (T.), of a daughter.

MARRIAGES.

GRIFFITHS—JAMES.—On August 13th, at Charles-street Congregational Church, Cardiff, Hugh Ernest Griffiths, M.B. Lond., F.R.C.S. Eng., to Doris Eirene, youngest daughter of the late Mr. W. H. James and Mrs. James, of Penylan, Cardiff.
IRVING—BRADSHAW.—On August 15th, at Crosthwaite Church, Keswick, Robert James Irving, F.R.C.S., to Violet Dorothy Gwenllian Pole, daughter of Edward H. G. Bradshaw, of Clifton, Bristol.
MALSEED—STUART.—On August 15th, at Waterside Presbyterian Church, Captain Alfred Malseed, M.C., R.A.M.C., attached King's Liverpool Regiment, to Eileen, daughter of the Rev. Dr. and Mrs. Stuart, Clifton Manse, Londonderry.
MILLER—GILFORD.—On August 15th, at St. Luke's Church, Reading, Reginald Miller, M.D., F.R.C.P., to Dorothy, daughter of the late William Gilford and Mrs. Gilford, of Wilmington, Wokingham-road, Reading.

DEATHS.

ALMOND.—Killed in action, August 9th, Captain George Hely-Hutchinson Almond, R.A.M.C., M.A., M.B., B.Ch. Oxon., aged 41, son of the late Hely-Hutchinson Almond, Headmaster of Loretto, and of Mrs. Almond, and dearly loved husband of Violet Almond (née MacCormac), 6, Brock-street, Bath.
GLASCOTT.—On August 14th, at Rosemullion, Budleigh Salterton, after a very short illness, Charles Edward Glascott, M.D., F.R.C.S., late of Manchester.
LISTER.—On August 9th, killed in action, Captain William Howard Lister, D.S.O., M.C., R.A.M.C., Fellow of University College, London, of Buxton, aged 31.
MENZIES.—On August 9th, killed in action, Lieutenant-Colonel Arthur J. A. Menzies, D.S.O., R.A.M.C., aged 32.
PROCTER.—On August 15th, at Brampton-Kinlet, Canford Cliffs, John Ward Procter, M.R.C.S., L.R.C.P., aged 84.
SCOTT-LAUDER.—On August 14th, at Helensburgh, Henry Scott-Lauder, Deputy Surgeon-General, R.N. (retired), aged 81 years.
WESTON.—On August 12th, after many years' illness, in Devonshire, Arthur Ernest Weston, L.R.C.P. Lond., M.R.C.S. Eng., age 47.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

The following journals, magazines, &c, have been received:—Medical Review, Shield, Bulletin of the Johns Hopkins Hospital, Journal of Nervous and Mental Disease, Middlesex Hospital Journal, Birmingham Medical Review, New Zealand Medical Journal, American Journal of Public Health, Canadian Practitioner, Therapeutic Gazette, Bulletin of the International Association of Medical Museums, Journal of Obstetrics, American Journal of Tuberculosis, Medical Journal of South Africa.

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.
Clinics each week-day at 2 P.M., Wednesday, Friday, and Saturday also at 10 A.M.
(Details of Post-Graduate Course were given in issue of August 3rd.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
Out-patients each day at 2.30 P.M.

THE THROAT HOSPITAL, Golden-square, W.
MONDAY, August 26th.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M., Clinical Lecture.

EDITORIAL NOTICES.

In consequence of the pressure on our space and the shortage of paper, the Editor may be compelled to abbreviate communications, as an alternative to their rejection, when time does not allow them to be reconsidered by their authors.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Communications, Letters, &c., to the Editor have been received from—

A.—Major A. Abrahams, R.A.M.C.; Col. J. G. Adami, A.D.M.S.; Mr. C. B. Andrews, Lond.; Mrs. V. Almond, Weston-super-Mare.
B.—Dr. F. Barlow, Lond.; Board of Agriculture and Fisheries, Lond.; Mr. W. H. Bowen, Cambridge; Mr. S. S. Barton, Liverpool; Dr. A. E. Brindley, Derby; Messrs. John Bale, Sons, and Danielsson, Lond.; Capt. P. Bahr, R.A.M.C.; British Dentists' Hospital, Lond.; British Hospitals, Association, Lond.; Mrs. C. Brereton, Lond.

Notes, Short Comments, and Answers to Correspondents.

THE HOUSEHOLD FUEL AND LIGHTING ORDER.

THE drastic demands of the Fuel Order may well give rise to anxiety for the coming winter. The shortage of coal means now not only a cutting down of the domestic supply of the fuel itself, but of the services of gas and electricity, which are, of course, terms interchangeable with coal. The allowance under the Order imply in no uncertain terms a very severe reduction in the quantities of coal, electricity, and gas which people have been accustomed to consume. Nor can the supplies be equalised on the old basis, for the consumer is informed that he is allowed so many units of gas, electricity, and coal, and he has the difficult task of deciding how to parcel out the allowances of each to his best advantage. If he takes his full allowance of coal, then he can have neither gas nor electricity. The quantity of gas and electricity allowed him is, in other words, dependent upon the reduction he is able to effect in the coal allowance, which already is probably in the large majority of cases a considerable reduction on past consumption. The situation is thus a very difficult one, and we may expect it will lead to one of the worst hardships inflicted upon us by the war so far as home conveniences are concerned. We are glad to see, however, that a clause provides for a special allowance for the invalid and infirm, as well as for the aged and young children. Temporary allowance in case of illness may be granted on production of a medical certificate. The public are advised to study very seriously how best they can tide over the crisis with the least discomfort. Attention should be given particularly to the use of wood, coke, and gas. As much coal as possible should be reserved for the gasworks, where it is economically used, and valuable by-products, including coke, obtained from it. It is devoutly to be hoped that the coming winter will not be severe.

CHLORETONE IN THE TREATMENT OF BURNS.

To the Editor of THE LANCET.

SIR,—I note in your issue of August 17th reference by Dr. H. Mallins to the use of chloretone in the treatment of burns. Until I became acquainted with the different preparations of flavine I used chloretone, not in powder form, but in a solution of olive oil, 30 gr. to 1 oz. I found that the introduction of chloretone relieved the pain and made dressing of the burns a comparatively painless process. The value of chloretone as a local anæsthetic also led me to introduce it into iodine solutions, so that the preliminary agony following the application of iodine solution to a raw surface was abolished.—I am, Sir, yours faithfully,

H. MEARNS SAVERY, M.R.C.S. Eng., L.R.C.P. Lond.

Cleethorpes, Lincs, August 20th, 1918.

TREATMENT OF INFLUENZA IN SWITZERLAND.

IN a useful article in the current number of the principal Swiss medical journal Professor R. Staehelin, of Basle, points out that little is really known of the actual death-rate from the present epidemic of influenza in Switzerland in spite of the alarmist returns in the press, inasmuch as the total number of cases is merely a matter of conjecture. Not much success appears to have attended any particular system of treatment. Professor Staehelin says:—

"We saw no effect from salvarsan, and only fleeting fall of temperature from optochin. Electrargol occasionally gave rise to rigor with resulting fall of temperature and definite improvement of general condition, but for the most part of transient nature. Subjectively antipyretics worked best (of these quinine showed no specially favourable effect), and in particular salicyl preparations, sweating being succeeded by a fall in the fever and increased comfort for several hours. In pneumonia camphor in large doses was the only effective remedy, with of course, venesection where indicated. We should welcome any suggestions from colleagues of a more effective remedy."

The same need is also being felt nearer home.

COLONIAL HEALTH REPORTS.

Bermuda.—According to the Blue-book for 1916, recently received at the Colonial Office, the Registrar-General estimates that the total resident civilian population at the end of the year was 21,215, composed as follows: White, 7282 (3477 male, 3805 female); coloured, 13,933 (6761 male and 7172 female). The birth-rate was 32·2 per 1000 among the resident civilian population, being 23·1 among white residents and 34·00 among coloured residents. The death-rate among resident civilians was 18·67. The illegitimate births were in the proportion of 14·42 per 100 births among the civil population (3·5 white and 18·4 coloured). The death-rate among white resident civilians was 14·42 per 1000 and among coloured residents 20·76. The European infantile mortality rate was 10·8 per 100 living births, and the rate among the coloured population 21·3 per 100, a considerable increase over the rate during 1915, which was 16·1 per cent. The mortality among children under 5 years of age was 35·2 per cent. of the total deaths (excluding stillbirths), as compared with 31·2 in 1915. The deaths from cancer among the resident civil population numbered 16, and those due to tuberculosis 39, being 5 among white inhabitants and 34 among coloured. No outbreak of serious infectious disease occurred. There is no hospital maintained by the Colonial Government, but during 1912 an Act was passed authorising the building of a general hospital, to be known as the King Edward VII. Memorial Hospital. The erection of this hospital was begun during 1913, but the works being interrupted by circumstances arising out of the war only about one-half of the structure was completed at the end of 1916. There is a cottage hospital near the city of Hamilton, which is supported by voluntary contributions, and hospitals are also maintained in connexion with the Imperial Naval and Military establishments. An asylum for the care and treatment of the insane was first established in this colony in 1846. The medical officer of health is the medical superintendent of the institution. Twelve patients (6 male and 6 female) were admitted into the asylum in 1916. Five patients were discharged and 12 died; 66 patients (32 male and 34 female) remained in the institution at the end of the year.

Mauritius.—Reporting on the affairs of the colony for the year 1916, Mr. L. Kœnig, Assistant Colonial Secretary, states that the estimated population, inclusive of Dependencies, was 384,253, an increase of 1513 on that of the previous year, and in the proportion of 492 males and 1021 females. There were 13,161 births, or 67 more than in 1915. The birth-rate was 35·0 per 1000 of the estimated population, as compared with 34·8 per 1000 for 1915. Of the births registered, 4280, or 32·5 per cent., were legitimate and 8881, or 67·5 per cent., illegitimate. The deaths registered were 11,432, or 1669 less than in the previous year. The death-rate was 30·4 per 1000 of the estimated population, as against 34·8, the death-rate in 1915, or a decrease of 4·4. Comparing the infant mortality with the births during the year, 13,161 infants were born and 1932 died at one year of age or under, equal to 16·9 per cent. The percentage under 5 years was 30·5. The principal causes of death throughout the colony during the year were: malaria, 32·6 per cent.; phthisis and other forms of tuberculosis, 18 per cent.; dysentery, 9·8 per cent. 227 cases of enteric fever were notified, with 52 deaths. Plague registered 22 attacks with 15 deaths, giving a death-rate of 68·2 per cent. Port Louis has been plague-free since April 6th, 1915. Trapping and poisoning of rats is carried out continuously. Rat-catchers accounted for 55,532 rats in Port Louis and 66,860 in the districts. Anti-malaria and anti-mosquito measures were continued during the year. The civil hospital in Port Louis, with 275 beds, is the most important of the colony. The number of patients admitted at this institution during the year was 6411, the number discharged 6060, and the daily average in hospital 246. The number of deaths was 329. Of those discharged 3128 were reported as cured, 2605 were relieved, and 327 were not improved. District hospitals are also maintained by Government at Barkly Asylum (Beau Bassin), Mahebourg, Souillac, Long Mountain, Poudre d'Or, Flacq and Moka, with an aggregate accommodation of 592 beds. The total number of cases treated at all district hospitals was 12,164, as against 12,782 in 1915. A new hospital is under construction at Candos, Quatre Bornes, to replace the present hospital buildings at Barkly Asylum. The outlying districts are served by dispensary hospitals and dispensaries for the treatment of emergency and pauper cases. The Immigration Law also requires the maintenance of hospitals on every estate on which there are 20 Indian indentured labourers. There were 72 inmates in the leper asylum at the close of the year, a decrease of 9 as compared with 1915.

THE RISKS OF ETHER IN THE OPERATING THEATRE.

A FATAL accident recently occurred in the operating theatre of the Germiston Hospital, near Johannesburg, South Africa. While preparation was being made for an operation a bottle of anæsthetic ether was upset, part falling on to a nurse's dress and part on a heating radiator, which at once ignited. The nurse with her dress on fire rushed into the corridor, where Dr. Spaulding extinguished the flames by wrapping her in a blanket, being himself burned in the act. The nurse died from her injuries, but the life of the child on the operating table was saved by the presence of mind of a second medical man, Dr. Th. Lund, who was present. In this country it is the rule not to use ether as an anæsthetic when there is any naked flame in the theatre, since it is well recognised that not only is the liquid inflammable but the invisible vapour itself is heavy, and may be wafted a considerable distance and take light unexpectedly.

THE LANCET.

LONDON: SATURDAY, AUGUST 31, 1918.

The Study of Clinical Medicine.

A RECENT debate, held under the auspices of the Abernethian Society at St. Bartholomew's Hospital, London, was devoted to discussion on a motion: "That ..... the study of surgery at the present time is of greater importance than the study of medicine." Major L. Bathe Rawling, R.A.M.C., who proposed the motion, contended that the mantle of medicine could readily be thrown over the surgeon, and that while the physician could not at the call of necessity wield the scalpel, the surgeon could at any time minister to the needs of the civilian population by consulting the stethoscope. Sir Thomas Horder and Dr. A. E. Stansfeld opposed the motion, the former on the ground that the fitness or otherwise of the recruit for military service was a matter almost solely in the hands of the physician, and that even in the actual field of war the surgeon's scope was limited, in that the vitally important first-aid work was best carried out by well-trained orderlies; while on the Eastern front the man with the knowledge of medicine was occupied all the time with malaria, dysentery, and other acute disease. At home the investigation and treatment of heart and nerve cases and of trench fever was fully occupying the attention of the physician, who was given to think more deeply than the surgeon. Dr. Stansfeld expressed the opinion that surgery could be more easily "picked up" than medicine, the third-year student demonstrably feeling less at a loss in the surgical than in the medical wards of a hospital. The motion was lost by a two-thirds majority.

We recognise that the debate was held in the informal atmosphere of a students' society, and that the champions of medicine and surgery doubtless were not so judgmatic in the expression of their views as they would have been on a more responsible occasion. But the report of the meeting, which we have derived from the *St. Bartholomew's Hospital Journal*, illustrates the striking fact that in the midst of war, with its myriad urgent claims, 80 or more students of a single metropolitan medical school were found to take part in debating an educational problem; and that, notwithstanding the wonderful success of war-time surgery, and its consequent glamour, they came to a conclusion which ranks clinical medicine as the principal subject for general study. For the verdict suggests that while medicine in its broadest sense is a scientific whole, internal medicine (or clinical medicine, as we generally call it) is to be regarded as the mother of all other clinical divisions. This conclusion has been repeatedly forced upon medical teachers on both sides of the Atlantic.

THE RENEWED INTEREST IN MEDICAL EDUCATION.

The debate and its outcome are significant at a time when we are witnessing an intense revival of interest in the whole subject of medical education, of which the effect cannot yet be foreseen, but which will certainly be nothing short of revolutionary. A forecast of this revival we may without false modesty see in the series of articles on medical education which appeared in our own columns nearly ten years years ago, and which were republished later in book form under the title "Some Considerations of Medical Education";[1] and these were immediately supplemented by the able reports on Medical Education[2] to the Carnegie Foundation for the Advancement of Teaching made by Abraham Flexner, on which more recent reformers have largely based their own schemes. The year which has elapsed since our last Students' Number has seen two further remarkable contributions to the study of medical education in this country. The first of these is the inquiry conducted under the auspices of the Edinburgh Pathological Club, the results of which have been published in instalments by the *Edinburgh Medical Journal* month by month since January, 1918, and are not yet concluded. The other is the Memorandum[3] on Medical Education addressed to the President of the Board of Education by the Chief Medical Officer, Sir George Newman. On these two sources we shall draw freely in what follows, giving actual quotations where these are likely to make for clearness.

[1] THE LANCET, ii., 1909. [2] Bulletin No. 4 (United States and Canada), 1910, No. 6 (Europe), 1912, Carnegie Foundation, New York City. [3] Cd. 9124, H.M. Stationery Office. 9d.

CLINICAL MEDICINE AND ITS IMPLICATIONS.

The modern conception of clinical medicine, which lies at the root of all the recent attempts made to realise it, defines the laboratory as a place constructed for the express purpose of facilitating the collection of data bearing on definite problems and initiating practical measures for their solution. Flexner finds that the hospital and the dispensary are laboratories in the strictest sense of the word. The practising physician and the "theoretical" scientist are thus, he says, engaged in doing the same sort of thing, even while one is seeking to correct a digestive aberration and the other to localise the cerebral functions of the frog.

"Certain conclusions as to clinical teaching follow. The student is to collect and evaluate facts. The facts are locked up in the patient. To the patient, therefore, he must go. Waiving the personal factor, always important, that method of clinical teaching will be excellent which brings the student into close and active relation with the patient: close, by removing all hindrance to immediate investigation; active, in the sense, not merely of offering opportunities, but of imposing responsibilities.

Clinical teaching has had substantially the same history as anatomical teaching. It was first didactic: the student was told what he would find and what he should do when he found it. It was next demonstrative: things were pointed out in the amphitheatre or the wards, those who got the front seats seeing them more or less well. Latterly it has become scientific: the student brings his own faculties into play at short range—gathering his own data, making his own construction, proposing his own course, and taking the consequences when the instructor who has worked through exactly the same process calls him to account: the instructor, no longer a fountain pouring forth a full stream of knowledge, nor a showman exhibiting marvellous sights, but by turns an aid or an antagonist in a strenuous contest with disease."

This is, in other words, the English method of clinical training in ideal if not in practice. The method has been generally lauded by American and Continental schools, and arose directly from the way in which the English schools originated, although in those days laboratories were undreamt of and physiology was almost an untouched branch of human knowledge. The medical schools of England were a development of the apprentice system. Originally students became doctors by learning their work through direct apprenticeship to their seniors, certain universities and corporations giving them degrees and diplomas afterwards, if such hall-mark was applied for and could be earned. Then hospital surgeons and physicians began to receive pupils at high fees who had the advantage of seeing the practice of the institutions to which their principals were attached. This procedure grew until first around individual surgeons and physicians, and later around the accommodating hospitals medical schools grew up. They were originally an integral part of the hospitals, for the students acted as the assistants of their principals in the treatment of the patients. This association of pupil and master became crystallised gradually into a system of clinical clerkships, surgical dressership, house physicianships, and house surgeonships. This method, it will be seen, never was that of a large class of obedient listeners to an authoritative professor. The relation was that of disciples serving and working under a leader. But the system no longer meets the position fully. Our students do not get the training which enables them to pass their examinations in a reasonable time. The fault lies somewhere between the teachers and examiners, both of whom are drawn from the same class and whose opportunities are given no fair scope; the teachers are ill-paid, the curriculum has become unwieldy; and the students do not face the exigencies of private practice as well equipped as they should be. These are the main things which have to be remedied, and while they are considered here in relation to clinical medicine, *mutatis mutandis* the remarks hold good over the whole field of medical education.

THE PRESENT UNSATISFACTORY POSITION.

One of the teachers of the Edinburgh School of Medicine describes the function of the school thus:—

"To turn out thoroughly qualified practical men, well versed in modern methods of investigating and treating

disease in its early and late stages—men imbued with a desire to help in advancing our knowledge of disease, recognising that in many directions their aid is both necessary and valuable."

This being the aim and scope of the study of clinical medicine, and being realised as such by practically every one who has taken the trouble to think out its general principles, why has not the practice been brought into harmony with the principles which have been so clearly enunciated? Certainly because it is not quite clear where reforms should begin. Flexner considers that our examination system is at fault, and has attacked it on the ground that too much deference is paid to seniority.

"The English profession," he writes, "governs and examines itself. But the active governors—those prominent in the corporations—are in the main elderly men, wise, seasoned, and eminent veterans to be sure, but in large measure veterans still. ..... To get a new point of view into the examination, chemical, pathological, or other, it must first be got into teaching. The ultimate reliance for ideals and intelligence must be on the schools as such, not on the schools acting under the coercion of examining bodies. ..... Now the official profession is eminent, dignified, and conservative—loyal to its past, deferential to the interests of the schools. ..... A change can be wrought only if a new spirit takes hold of education; it is not likely that stubborn or long resistance to revising the examinations would be made, once a revolution in educational sentiment has been accomplished."

We have, of course, heard an enormous amount of criticism of examinations and examiners, and no one suggests that medical students are not an over-examined class; but reform of examinations can follow upon reform in the educational curriculum as easily as it can precede it, and perhaps it is the curriculum that should be amended first. As regards deference to seniority, a writer in the *St. Mary's Hospital Gazette* said bluntly some months ago:—

"Test everything possible for yourself, and do not place too blind a trust in books or teachers; uncritical respect for one's elders and betters is irreverence in a scientific man."

This spirit has its faults as well as its merits; it makes the work of the instructor very difficult, and so diminishes the good that he might do to less independent students. Originality would be thus kept unimpaired, but the independent-minded students would not pass their tests under the existing state of things. Before it would be practically safe for the student to follow the above counsel, with which we much agree, it will be necessary for the medical curriculum to become less a series of unconnected, if parallel, paths, and more a broad and continuous highway upon whose surface there is room for some alternations of courses. General education would then rank above particular instruction, and examinations would become more flexible.

REFORM OF THE EXAMINATION SYSTEM.

To determine that the present position of medical examinations is wrong is one thing and to analyse the defects with a view to their removal is another. Professor G. Lovell Gulland regards it as essential to make the final examinations both more practical and more searching. In clinical medicine he would discard the farce of "spotting" urines and microscopical specimens. We ought, he says, to insist on real urine-testing, real chemical examination of other substances, and real microscopic work.

"We should also consider the advisability of including in the final examination the results of class examinations and the work in the wards, so as to encourage steady work and discourage spurting. We all know that neither the student nor the examiner is always at his best at an oral examination. Confidential reports from the systematic and clinical teachers might well take their place in determining whether man should pass his final, and at what level."

The same solution is proposed by Sir George Newman, speaking from his experience as medical assessor to the Universities Branch of the Board of Education:—

"A vast and almost immediate benefit would accrue to the whole business of clinical education in this country if the whole basis of the Degree Examinations was the training the student had received and not certain items of information which, on a given date, he was able to furnish to the examiner. If the medical work of the examinee was assessed—his theoretical and practical work, his preparations, slides and drawings, his reports of cases, the records of his clerking, dressing, and clinical pathology, and the results of his class examinations—and could form a substantial portion of the Degree Examination, we should immediately see an improvement in the system of education. Cramming and other forms of alchemy would disappear, and the purpose of training would be its own intrinsic value, the equipment of a practitioner of medicine and surgery, and not an artificial test on a theoretical basis at a given date in an examination hall."

This is a return to a policy which has been advocated for many years, but has always been addressed to deaf ears. The policy is supposed to imply eventually the examination of the students by their own teachers, and this again is supposed to be a retrograde procedure. But is either deduction true? It ought to be quite easy to have such a proportion of extern examiners that there would be no risk in allowing the actual teachers some share in the fate of their students; and it is certain that students could work with smaller apprehension of their fate and more determination to acquit themselves well in the eyes of their teachers if the latter were known to have a voice in the issue. In talking of the vices of the examination system we must always remember that while the curriculum is undoubtedly influenced by the character and standard of its examinations, so the character and standard of the examinations are influenced by the curriculum. If, for example, the curriculum is disjointed, the examination will generally be fussy and meticulous in detail, rather than directed towards broad principles of learning.

THE IMPERFECTIONS OF THE MEDICAL CURRICULUM.

The various plans laid down by the qualifying bodies for the medical curriculum of their students will be found fully set out as usual in the Students' Number of THE LANCET, and it will be seen that all these plans conform practically to one pattern. The student first learns the general sciences of chemistry, biology, and physics up to the point where he is introduced to the special sciences of human anatomy, physiology, and pharmacology, those being the divisions of biology and chemistry on which his professional education will be founded. Then come hospital practice, theoretical and practical medicine, surgery, and obstetrics, the pathology and therapeutics of all these being illustrated by the patients receiving attention at the hospital either as in-patients or out-patients. Under the Medical Acts the student is supposed to occupy five years of training in his studies between the time of entering the medical school and the time of obtaining his degree or diploma from a University or corporation. As a matter of fact, the average time taken is over six years, and on this ground alone the curriculum has been much criticised. Further, it is doubtful whether the young man, so large a slice of whose life is occupied in professional training—all of which must be really preliminary to the acquisition of professional wisdom—is as well equipped as he might be considering the money and trouble expended. There seems to be a consensus of opinion that he is not. Sir George Newman finds that there is a lack of scientific spirit in the curriculum; the Edinburgh critics find that the neglect to instruct students in incipient disease and early symptoms renders the first years of their professional life very difficult ones; and thirdly, on all hands it is admitted that the student is given too much to learn in the allotted time. But the essential blot on the system, which if it is particularly clear in the case of clinical medicine is present also in the cases of surgery and obstetrics, is the want of continuity in the training. The student finds at each stage that he has too much to learn, because what he has learned in the past is not made to help him sufficiently in the later stages. This is a lack of scientific spirit.

LACK OF SCIENTIFIC SPIRIT.

A larger measure of the scientific spirit is Sir George Newman's first requisite in adapting the teaching of clinical medicine to the needs of the time. How difficult this is to ensure even in London with its unlimited opportunities he illustrates by a painful example:—

"Here is a London medical school of the first rank with a large and eminent staff, but there is only one clinical lecture per week, or 12 in a term; here are four other London medical schools with the attendance of the clinical teaching staff irregular, intermittent, and unreliable owing to the prior claims of practice; and here is an example of a school where the physicians and surgeons teach only their own clerks."

He concludes that the result of such conditions is absolutely to preclude clinical teaching of university standard, and all reformers of education are working towards the University degree as the only proper termination of an

academic and practical course of training. Twenty years ago such an ideal would have had little foundation; to-day it is the inevitable outcome of the rise of a large group of provincial universities, well equipped materially and educationally, and infused with an ardent spirit of progress.

It is difficult to agree that the absence of clinical lectures connotes the absence of the scientific spirit, but we are perfectly sure that the medical curriculum is not interpreted by its exponents, either teachers or taught, in the ways that lead to the highest mental development or the finest conceptions of medicine. And the reason for this is mainly the lamentable want of continuity in studies, so that the student hardly perceives while he is learning pathology that he is dealing with modified physiology, while the clinical teacher who finds himself in contact with a question of chemistry cannot elucidate the points for his class, even if he perceives the connexion, because he has forgotten them, having from his practical, but hopelessly unscientific, point of view no reason to remember them.

Edinburgh is wide awake to the need of raising the standard of clinical teaching, and the medical faculty has drawn up a memorandum of changes desirable after the war. These include a limitation in the size of clinics, subdivision of classes for junior and senior students, closer supervision of case-taking, a fuller utilisation of the services of the assistant physicians, and the following up of cases to the post-mortem room. The last of these things is exactly illustrative of what was said above—that the lack of scientific spirit leads to lack of continuity. The post-mortem examination is the last chapter in the most fateful of the hospital stories which it is the student's privilege to read, and that last chapter he may never hear of!

NEGLECT OF DISEASE IN ITS EARLIEST STAGES.

Failure to deal with the early or incipient stages of disease has been a very usual reproach against the medical curriculum because when the young practitioner first faces his public it is upon early and correct diagnosis that his utility and future will largely depend. It must be admitted that incipient cases of disease do not find their way in bulk into hospitals; but this is a direction where teachers should ever be on the alert to furnish out of their experience lessons which the ward or the out-patient department for the moment is not supplying. The absence of enthusiasm among Edinburgh students for medicine as contrasted with the intense attraction exerted by present-day surgery is noted, and will be seen to be in direct opposition to the way in which the Abernethian Society of St. Bartholomew's Hospital registered their votes. This apathy is attributed by Dr. Chalmers Watson in part to the fact that hospital students are continually seeing cases of chronic disease which remain for months and leave the wards very much *in statu quo*. The neglect of dispensary teaching is lamented by the younger Edinburgh men, who regard dispensary practice as of great value to the student.

"A great part of his afterwork consists in the recognition and treatment of minor maladies, which he does not, and cannot, see in the wards of the infirmary, but which are of everyday occurrence in dispensary practice. Dispensary teaching should be definitely coördinated with the teaching in the infirmary. ..... If this arrangement were carried out the teaching of medicine from the curative point of view could be brought into line with teaching from the preventive point of view."

Professor Gulland agrees that the weak point in the present teaching is that it is conducted on hospital patients—i.e., either on people so seriously ill that they cannot be handled by large numbers of students, or else on cases of well-established disease, excellent enough for physical signs, but not admitting of really curative or preventive treatment.

WHAT IS THE VALUE OF SYSTEMATIC LECTURES?

The Edinburgh faculty has devoted special attention to the place of systematic lectures in the curriculum. Clinical medicine to Professor Harvey Littlejohn *is* the teaching of medicine, and he adds:—

"Systematic medicine ought simply to be giving the student a general outline of various diseases. My idea of systematic lecturing is that the lecturer should be simply like a guide taking a number of people round a picture gallery, devoting the greater part of the time to those pictures which are standards in art. He should point out the characters of all the pictures, but devote special attention to those which really may be taken as outstanding types."

It is noteworthy that attendance at certain groups of systematic lectures has been made optional for the duration of the war by London University and other examining boards, and this course was taken, no doubt, because the war has removed so many of the competent guides from the class-rooms to the zones of battle. In the special case of medicine Dr. Robert Thin considers such lectures to be simply a relic of mediæval times, when books were non-existent or were too expensive to be in the hands of students. Dr. Edwin Matthew, speaking for himself and the other Edinburgh assistant physicians, regards the attempt to give in the course of two hundred lectures a more or less complete account of diseased conditions (their recognition, results, and treatment) as a mere dictation exercise, of little benefit to the student. Professor William Russell sees the advantage of retaining the systematic course embodying the complete knowledge of an experienced lecturer for the sake of the sense of perspective so necessary for the student. Professor Gulland finds the text-book out of date almost from the moment of its publication, but humorously suggests that the lecturer at all events derives untold benefit from reviewing his knowledge in every department of medicine at least once a year. Dr. Ivy McKenzie's suggestive idea of coördinated work is a special systematic lecture at the end of each week, dealing with the subject demonstrated in detail at ordinary clinical lectures during the week. A fruitful line of coördination is sketched by Professor Lorrain Smith, who says that the attempt has lately been made in Edinburgh to make the study of pathology introductory to the subjects of medicine and surgery—

"by making the main part of our course the teaching of how the story of disease in a given case is to be read in pathology in correspondence with the clinical observations and history of the case. ..... By thus coördinating the work of these departments a great deal of introductory matter could be got over, and physiology, anatomy, and pathology could be made more interesting to the students, who would arrive at medicine not unfamiliar with the living patient."

In pathology, he adds, systematic lectures are of little importance until the student has a basis on which to build.

In London the yoke of the systematic lecture has pressed all too heavily in recent years. A writer in one of the hospital gazettes hardly exaggerated the position in the following words:—

"The habit of lecture attendance grows; the student gains a greedy appetite for them, until in his final years he (or she) spends most of his time in passing from one lecture-room to (sleep in) another. And on those rare occasions when there are no lectures the armchairs around the library fires become filled rather than the laboratory, wards, or museum."

We agree with this writer in thinking that the blame lies with the system rather than with the student, but if lectures were of the character postulated by Dr. Ivy Mackenzie, and took the form of a topical résumé of a week's hospital work in a definite direction, the value of such teaching would at once appear. In this way the past and present work of the student would be constantly revised and coördinated.

SIMPLIFICATION AND ORGANISATION.

We have alluded to the errors and omissions in the present system of teaching in clinical medicine not in any despondent spirit, but because we believe that now is the time when old and worn-out methods may be discarded and our faces set in the direction of new and fruitful effort. The general directions which progress should take are fairly obvious, and what applies to clinical medicine applies also in large measure to other sections of medical education.

The curriculum is overloaded, for the students cannot pass their examinations in reasonably high numbers in the allotted time. The large average of failures in examinations may be due, in part, to the nature of the tests devised; and, in part, to the disjointed nature of the educational course. Two remedies suggest themselves. The first is that as far as possible the study of the ancillary scientific subjects should be carried on at a secondary school, though in some divisions of the United Kingdom State aid might here be needed. The second is that continuity in scientific and pathological training should be instituted at all medical schools by a properly paid corps of teachers in touch with each other's work. Medical examinations, reformed to test the merits of students thus educated, would then meet both professional and public needs.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

POWERS, DUTIES, AND CONSTITUTION OF THE GENERAL MEDICAL COUNCIL.

THE powers and duties of the General Medical Council or "General Council of Medical Education and Registration of the United Kingdom" to give the Council its full title, have been set out in detail in many previous Students' Numbers of THE LANCET. It is first a registering body: no person, even though his qualifications have been obtained, is a legally qualified medical practitioner unless his name appears on the Medical Register. Secondly, it is a standardising body, ensuring that the education of medical men is kept up to an efficient standard by scientific examination. Thirdly, it is a penal and disciplinary body, having power to remove from the Register any practitioner adjudged guilty of conduct "infamous in a professional respect." Fourthly, to the Council is committed the codification of pharmaceutical remedies.

The duties of the Council are thus primarily of a public nature, and its construction shows its fitness for its fourfold responsibilities.

The Council at present consists of 38 members, of whom, as will be seen by the annexed list, all but 11 are official representatives of some corporate body. Five members are chosen by the Crown on the advice of the Privy Council, and six others are elected by the members of the medical profession as Direct Representatives.

President of the General Council: Sir Donald MacAlister, Members of the General Council: Dr. Norman Moore, chosen by the Royal College of Physicians of London; Mr. Holburt Jacob Waring, Royal College of Surgeons of England; Mr. Meredith Townsend, Apothecaries' Society of London; Mr. Arthur Thomson, M.B., F.R.C.S., University of Oxford; Mr. Frederick Gowland Hopkins, M.A., M.B., University of Cambridge; Dr. Robert Howden, University of Durham; Sir Frederick Taylor, University of London; Dr. Grafton Elliot Smith, Victoria University of Manchester; Mr. Harry Gilbert Barling, C.B., University of Birmingham; Dr. Richard Caton, University of Liverpool; Dr. Alfred George Barrs, University of Leeds; Mr. Rutherfoord John Pye-Smith, University of Sheffield; Sir Isambard Owen, University of Bristol; and Dr. David Hepburn, C.M.G., University of Wales. Dr. William Russell, chosen by the Royal College of Physicians of Edinburgh; Mr. James William Beeman Hodsdon, Royal College of Surgeons of Edinburgh; Dr. David Neilson Knox, Royal Faculty of Physicians and Surgeons of Glasgow; Dr. H. Harvey Littlejohn University of Edinburgh; Sir Donald MacAlister, University of Glasgow; Dr. John Theodore Cash, University of Aberdeen; and Dr. John Yule Mackay, University of St. Andrews. Sir John William Moore, chosen by the Royal College of Physicians of Ireland; Sir Arthur Gerald Chance, Royal College of Surgeons in Ireland; Dr. Edward Magennis, Apothecaries' Hall of Ireland; Dr. Arthur Francis Dixon, University of Dublin; Sir Bertram Coghill Alan Windle, National University of Ireland; and Dr. Johnson Symington, Queen's University of Belfast. Nominated by His Majesty, with the advice of his Privy Council: Mr. Charles Sissmore Tomes, Sir Arthur Newsholme, Sir Francis Henry Champneys, Dr. John Christie McVail, and Dr. Edward Coey Bigger. Elected as Direct Representatives: Dr. Langley Browne, Dr. H. A. Latimer, Dr. J. A. MacDonald, Mr. Thomas Jenner Verrall, Dr. Norman Walker, and Dr. Leonard Kidd. Treasurers of the General Council: Mr. Charles Sissmore Tomes and Sir Frederick Taylor.

THE EDUCATIONAL CURRICULUM.

Professional Education.—The course of professional study after registration occupies at least five years. The Final Examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

Registration and Preliminary Examination of Medical Students.—The following are the General Medical Council's Regulations in reference to the registration of students in medicine.

Every medical student should be registered in the manner prescribed by the General Medical Council. The registration of medical students is placed under the charge of the Branch Registrars. Every person desirous of being registered as a medical student should apply to the Branch Registrar of the division of the United Kingdom in which he is residing; and should produce or forward to the Branch Registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and evidence that he has attained the age of 16 years, and has commenced medical study at an institution approved by the Council. The Branch Registrar shall enter the applicant's name and other particulars in the Students' Register and shall give him a certificate of such registration. Each of the Branch Registrars shall supply to the several licensing bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. The commencement of the course of professional study recognised by any of the qualifying bodies should not be reckoned as dating earlier than 15 days before the date of registration. In addition to the universities and schools of medicine there are many institutions where medical study may be commenced. Applications for special exceptions are dealt with by the Students' Registration Committee, which reports all such cases to the Council.

Regulations for the Maintenance of the Register of Medical Students.

The following examinations have been approved by the Council:—(*a*) The final examinations for the degrees in Arts and Science of any University of the United Kingdom or of the British Dominions. (*b*) All examinations which are accepted for Matriculation in the Faculties of Arts and Science in any one of the Universities of Great Britain, provided the pass-certificate (or certificates) includes English, Mathematics, and at least two other subjects named in the following list:—Latin, Greek, Hebrew, Arabic, Persian; French, German, Spanish, Italian, Russian, or any approved modern language; History, Geography, Natural Philosophy or Physics, Chemistry, Biology, Physical Geography, Geology. (*c*) All examinations not included under the foregoing section (*b*), which are accepted for Matriculation in the Faculty of Medicine in any one of the Universities of the United Kingdom of Great Britain and Ireland provided the examination is completed at not more than two periods of examination, and that the pass-certificate (or certificates) includes English, Mathematics, Latin (or Greek or Hebrew), and at least one other subject named in the following list:—Latin, Greek, Hebrew, Arabic, Persian, French, German, Spanish, Italian, Russian, or any approved modern language. (*d*) The Council may grant special recognition to the following examinations not included under the foregoing sections (*a*), (*b*), and (*c*):—(1) The final examinations for the degrees in Arts and Science of any specially recognised Foreign University. (2) Examinations conducted by approved Examining Bodies within the United Kingdom under the provisions set forth in the foregoing section (*c*). (3) Examinations conducted by approved Examining Bodies out of the United Kingdom under the provisions set forth in the foregoing section (*c*), and under such other conditions as the Council may impose in each case.

List of Bodies whose Examinations are accepted under the Foregoing Regulations.

I. *Examinations in Great Britain.*

(1) The Matriculation Examinations in the Faculties of Arts of Science of, and all examinations accepted in lieu thereof by, the following Universities: Oxford (including Responsions and Moderations), Cambridge (including the Previous Examination and the General Examination), Durham, London, Manchester, Birmingham, Liverpool, Leeds, Sheffield, Bristol, Wales, Edinburgh, Glasgow, Aberdeen, St. Andrews. These examinations are accepted subject to the conditions set forth under Section 2 (*b*) above. (2) The Preliminary Examinations in the Faculty of Medicine of, and all examinations accepted in lieu thereof by, the Universities of Durham, Edinburgh, Glasgow, Aberdeen, St. Andrews. These examinations are accepted subject to the conditions of Section 2 (*c*) above. (3) Specially recognised Examinations conducted by approved bodies.

The following Schools Examinations have been recognised by the English Board of Education and are accepted by the General Medical Council under the conditions noted below:—

AS FIRST EXAMINATIONS.

1. The School Certificate Examination of the Oxford and Cambridge Schools Examination Board.
2. The Senior Local Examination of the Oxford Delegacy for Local Examinations.
3. The Senior Local Examination of the Cambridge Local Examinations and Lectures Syndicate.
4. The School Certificate Examination of the University of Bristol.
5. The First School Certificate Examination of the University of Durham.
6. The General School Examination of the University of London.
7. The School Certificate Examination of the Northern Universities Joint Matriculation Board.

AS SECOND EXAMINATIONS.

8. The Higher Certificate Examination of the Oxford and Cambridge Schools Examination Board.
9. The Higher School Certificate Examination of the Oxford Delegacy for Local Examinations.
10. The Higher School Certificate Examination of the Cambridge Local Examinations and Lectures Syndicate.
(*a*) 11. The Higher School Certificate Examination of the University of Bristol.
12. The Higher Certificate Examination of the University of Durham.
(*a*) 13. The Higher School Certificate Examination of the University of London.
14. The Higher Certificate Examination of the Northern Universities Joint Matriculation Board.

(*a*) These Examinations will be held for the first time in 1919.

In the First Examinations: School Certificates ("passes with credit") and in the Second Examinations: Higher Certificates, provided in both instances that they fulfil the conditions required for Matriculation in the Faculties of Arts or Pure Science in any University of Great Britain, are accepted by the General Medical Council under Clause 2 (*b*); otherwise they are accepted under Clause 2 (*c*), provided that evidence is afforded that all the subjects required by the Council have been actually passed on an approved standard. (*Applicants are advised to apply to the Examining Bodies for the necessary evidence.*)

Other Certificates accepted under Clause 2 (*b*). Scottish Education Department: Leaving Certificates.

Other certificates accepted under Clause 2 (*c*). Intermediate Certificate. Central Welsh Board: Senior Certificate. University of St. Andrews: Final Examination for Diploma of L.L.A. College of Preceptors: Senior Certificate; Preliminary Examination for Medical Students Certificate. Educational Institute of Scotland: Preliminary Medical Examination Certificate.

II. *Irish Examinations.*

University of Dublin: Matriculation Examination: (*a*) Junior Freshman Term Examination (exclusive of Trigonometry); (*b*) Special Preliminary Examination to be held in March, the standard and subjects of which shall be those of a Junior Freshman Examination (exclusive of Trigonometry); (*c*) Junior Exhibition Examination on obtaining marks of sufficient merit in the subjects of (*a*) or (*b*); (*d*) Examinations for the First, Second, Third, or Fourth Year in Arts. (Certificate to be signed in the approved form by the Medical Registrar of the University.) Queen's University of Belfast: Matriculation Examination. National University of Ireland: Matriculation Examination. Intermediate Education Board of Ireland: Middle Grade Examination, with Honours in three subjects; Senior Grade Examination. Royal Colleges of Physicians and Surgeons in Ireland: Preliminary Examination. These Examinations are accepted subject to the conditions set forth in Section 2 (*c*) above.

The remainder of the curriculum, though all under the supervision of the Council, is in detail in the hands of the various degree- and diploma-granting bodies whose representatives are members of the General Medical Council. In the next pages we give the regulations of the various examining bodies, but it must always be remembered that the examinations are under the supervision of the General Medical Council, who visit the various centres in turn and closely inspect the procedure.

III. *Examinations Held Out of the United Kingdom.*

Every Certificate from Indian, Colonial, and Foreign Universities and Colleges must contain evidence that the Examination has been conducted by or under the authority of the Body granting it, must include all the subjects required by the General Medical Council, and must state that all the subjects of Examination have been passed in at not more than two examinations; copies of the form of the required Certificate are supplied by the Registrar of the Council for the purpose. In the case of Natives of India or other Oriental countries whose vernacular is other than English an Examination in a Classical Oriental Language (e.g., Sanskrit, Arabic, Chinese) may be accepted instead of an Examination in Latin. The German Abiturienten-Examen of the Gymnasia and Real-Schulen and the examinations entitling to the French diplomas of Bachelier ès Lettres and Bachelier ès Sciences and other corresponding Entrance Examinations to the Universities in Europe are recognised by the General Medical Council.

These examinations are accepted subject to the conditions set forth in Section 2 (*c*) above.

Further particulars are given in the Students' Regulations, which can be obtained at the offices of the Council, price 9*d*.

The Officers of the Council.

Norman C. King, Registrar of the General Council and of the Branch Council for England, 44, Hallam-street, Portland-place, W. 1.—James Robertson, Registrar of the Branch Council for Scotland, 54, George-square, Edinburgh.—Richard J. E. Roe, Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin. All communications should be addressed to "The Registrar" and not by name.

POSTPONEMENT OF THE ELECTION OF DIRECT REPRESENTATIVES.

By an Order in Council dated August 14th the provisions of the Parliament and Local Elections Act, 1918, have been extended to the election of members of this Council by registered practitioners resident in the United Kingdom, the effect of which is to extend the term of office of the existing Direct Representatives until Dec. 31st, 1919. Accordingly no election of Direct Representatives will fall to be held in the present year.

THE MEDICAL EXAMINING BODIES AND SCHOOLS OF THE UNITED KINGDOM.

A GUIDE TO THE FACILITIES FOR OBTAINING THE VARIOUS MEDICAL DEGREES AND OTHER QUALIFICATIONS FOR THE BRITISH MEDICAL REGISTER.

I.—ENGLAND AND WALES.

THE UNIVERSITIES.

UNIVERSITY OF OXFORD.

THERE are two degrees in Medicine, *B.M. and D.M.*, two degrees in Surgery, *B.Ch. and M.Ch.*, and two diplomas, *Public Health* and *Ophthalmology*.

Graduates in Arts (B.A. or M.A.) are alone eligible for the degrees. The most convenient course for the B.A. degree for intending graduates in Medicine is to take Responsions, the Preliminary Science Examinations mentioned below, and the Final Honour School of Physiology. In order to obtain the degrees of B.M. and B.Ch. the following examinations must be passed:—1. Preliminary subjects: Mechanics and Physics, Chemistry, Zoology, and Botany. 2. Professional. (*a*) First Examination: Subjects—Organic Chemistry, unless the candidate has obtained a first or second class in Chemistry in the Natural Science School; Human Physiology, unless he has obtained a first or second class in Animal Physiology in the Natural Science School; Human Anatomy. (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene, Materia Medica and Pharmacology. The approximate dates of the examinations are as follows:—Preliminaries—Zoology, Botany, and Chemistry, December and June; Mechanics and Physics, March and June; Professional (First and Second B.M.), June and December.

The First Examination for the degrees of B.M. and B.Ch. may be passed as soon as the Preliminary Scientific Examinations have been completed. Anatomy and Physiology are to be passed together, and Organic Chemistry may be taken before or after these have been passed.

The Second Examination may be passed after the completion of the first, but Pathology, Hygiene, and Materia Medica and Pharmacology may be taken before or with the remaining subjects. Before admission to the Second Examination candidates must present certificates of attendance on a course of laboratory instruction in Practical Pathology and Bacteriology and of having acted as post-mortem clerk for three months, surgical dresser for six months, and clinical clerk for six months. Also they must produce certificates of instruction in Infectious and Mental Diseases, and of attendance on Labours, of proficiency in the practice of Vaccination and Anæsthetics, and of having attended a course of Practical Pharmacology. Also in respect of the First Examination candidates must present

certificates showing that they have dissected the whole body once and have attended courses of laboratory instruction in Practical Histology and Practical Physiology.

The degree of D.M. is granted to Bachelors of Medicine of the University provided they have entered their thirtieth term and have composed on some medical subject a dissertation which is approved by the professors in the Faculty of Medicine and examiners for the degree of B.M. whose subject is dealt with. The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-first term, who are members of the surgical staff of a recognised hospital, or have acted as Dresser or House Surgeon in such a hospital for six months, and who have passed the M.Ch. examination in Surgery, Surgical Anatomy, and Surgical Operations. This examination is held annually, in June, at the end of the Second B.M. Examination.

Diploma in Ophthalmology. — This diploma has been suspended during the war.

Travelling Fellowship, Scholarships, and Prizes. — A Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for three years and is of the annual value of £200. The examination is in Physiology, Pathology, and Hygiene, and is partly "practical." Candidates must be graduates in Medicine of the University. The holder must travel abroad for the purpose of medical study. Application should be made to the Radcliffe Examiners, Radcliffe Library, University Museum. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology. The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennially for research in some branch of medical science. The Theodore Williams Scholarships of the value of £50 each are awarded annually in the subjects of Anatomy, Physiology, and Pathology. A King's College Hospital Burney Yeo Scholarship of £80 is awarded each year. The Scholarships in Science which are offered by several Colleges are open to those who intend to pursue Medicine. The value of these scholarships is usually £80 a year for four years.

In addition to the University lectures and classes the several Colleges provide their undergraduates with tuition for all examinations up to the B.A. degree.

In the Radcliffe Infirmary and County Hospital clinical instruction is given by the Regius Professor of Medicine, the Litchfield Lecturers in Medicine and Surgery, and the other physicians and surgeons. Instruction is also given in post-mortem work and Clinical Pathology in connexion with the courses in Pathology.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1918 (both of which are published by the Clarendon Press); from the Regius Professor of Medicine; and from the Professors in the several departments of medical science. Certain special conditions as regards students who have been engaged on war service may be obtained on application to the Assistant Registrar of the University, Clarendon Building, Oxford.

UNIVERSITY OF OXFORD: RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—Courses of instruction are given in connexion with the Oxford University Medical School. These include (1) a course in Practical Medicine by the Regius Professor of Medicine; (2) Clinical lectures by the Litchfield Lecturers in Medicine and Surgery; and (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation. (4) Pathological demonstrations and instruction in post-mortem work are given by the Assistant Pathologist. Practical Pharmacy is taught in the Radcliffe Dispensary. Opportunities are offered to students who wish to act as surgical dressers and clerks. The Hospital contains 170 beds.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep nine terms (three years) by residence in the University. He must pass the Previous Examination in Classics, Mathematics, &c., if possible, before he comes into residence in October, or he may obtain exemption through the Oxford and Cambridge Schools Examination Board, the Oxford or Cambridge Senior Local Examinations, the London Matriculation Examination, the Scotch Education Department, Responsions at Oxford, and the Joint Matriculation Board of the Universities of Manchester, Liverpool, Leeds, and Sheffield, the Matriculation Examination of the University of Birmingham, or by being graduates of certain other Universities in the United Kingdom. He may then devote himself to medical study in the University, &c. Or he may, as nearly all students now do, proceed to take a degree in Arts by passing either (*a*) the General Examination and one Special Examination, or (*b*) two Special Examinations for the ordinary B.A. degree, or an Honours degree in one of the Triposes. The Natural Sciences Tripos is taken most frequently, as some of the subjects are practically the same as those for the first and second M.B.

For the degree of *Bachelor of Medicine* (*M.B.*) five years of medical study are required either in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge till he has passed, say, the examination for Part I. of the Natural Sciences Tripos and the first and second examinations for M.B. Hospital practice and many of the requisite lectures may be attended in Cambridge, and some students remain to attend lectures and hospital practice until they have passed the second part of the second examination for M.B. The laboratories for Botany, Chemistry, Physics, Biology, Zoology, Human Anatomy, Physiology, Biochemistry, Pathology, Bacteriology, Pharmacology, Psychology, and Public Health are well equipped. Addenbrooke's Hospital, the Infectious Diseases Hospital, the Cambridge Research Hospital, and the Field Laboratories are utilised for study and research.

There are three examinations for M.B. The *first* includes (1) Chemistry and other branches of Physics, and (2) Elementary Biology. These parts may be taken together or separately. The *second* is divided into two parts—viz., (1) Human Anatomy and Physiology; and (2) Pharmacology and General Pathology. The *third* is also divided into two parts: (1) Principles and Practice of Surgery (including Special Pathology and Midwifery and Diseases Peculiar to Women); and (2) Principles and Practice of Physic (including Diseases of Children, Mental Diseases, Medical Jurisprudence), Pathology (including Hygiene and Preventive Medicine), and Pharmacology (including Therapeutics and Toxicology). The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting room, and in the laboratories. An Act has then to be kept in the Public Schools, by the candidate reading an original dissertation composed by himself and being examined orally on some subject approved by the Regius Professor of Physic.

Candidates who have passed both parts of the third M.B. examination are admitted to the registrable degree of *Bachelor of Surgery* (*B.Ch.*) without separate examination and without keeping an Act.

The degree of *Doctor of Medicine* (*M.D.*) may be taken three years after that of M.B. or four years after that of M.A. The candidate is required to produce certificates of having been engaged in Medical Study for five years, and if an M.A., to pass the same examinations as are required for the degree of M.B. An Act has to be kept, consisting of an original Thesis sustained in the Public Schools with *viva voce* examination; and a short extempore essay has to be written on a topic taken from the general subject of his thesis, whether it be Physiology, Pathology, Pharmacology, the Practice of Medicine, State Medicine, or the History of Medicine.

For the degree of *Master of Surgery* (*M.Ch.*) the candidate must have passed all the examinations for B.C., or, if he is an M.A., have obtained some other registrable qualification in surgery. He is required either (1) to pass an examination in Principles and Practice of Surgery, Surgical Anatomy and Surgical Operations, and Pathology, and to write an extempore essay on a Surgical Subject; or (2) to submit to the Medical Board original contributions to the advancement of the Science or Art of Surgery. Before he can be admitted to the examination two years at least must have elapsed from the time when he completed all

required for the degree of B.C. Before submitting original contributions he must have been qualified at least three years.

Women Students.—Increased facilities have been offered to students of Girton and Newnham Colleges, and they are admitted to the First and Second M.B. Examinations under certain conditions.

University Prize in Medicine.—The one University Prize in Medicine, the Raymond Horton Smith Prize (value £19), is awarded to that candidate for the degree of M.D. who presents the best thesis for the degree during the academical year, provided that he has taken honours in a tripos examination. Medical Studies are endowed by the numerous Natural Science scholarships at the various colleges, information about which can be obtained from the respective Tutors.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, Pharmacology, and General Pathology may be obtained upon sending a stamped directed envelope to the Registrary, the Registry, Cambridge.

ADDENBROOKE'S HOSPITAL.—Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are given at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery is given in the wards and out-patients' rooms by the physicians and surgeons daily during the term time and vacations. The fee for pupilship is 3 guineas a term. All communications by students should be made to Dr. Aldren Wright.

UNIVERSITY OF LONDON.

The University of London was established by Royal Charter in 1836 as an examining and degree conferring body with affiliated colleges but no direct teaching functions. In 1900 it was reconstituted under the Act of Parliament 1898 and became a teaching as well as an examining body. Many schools already existing became constituent colleges, including all the metropolitan medical schools. Teachers were also appointed in special subjects to give lectures at the University.

Teaching Staff.—The teaching staff of the University is organised under two heads: 1. Appointed teachers—i.e., such as are appointed by, and are paid out of the funds of, the University. 2. Recognised teachers—i.e., those who have been appointed and are paid by the several schools of the University and other institutions at which instruction is given under the auspices of the University, and who have been recognised by the Senate as conducting work of University standard. Courses by non-recognised teachers may also be approved in schools of the University. The lecturers in the Medical Sciences and the professors in the Faculties of Medicine in University College, London, and King's College, London, will be found enumerated under their respective medical schools.

Internal and External Students.—All the examinations of this University are open to men and women alike. Matriculated students of the University may be either internal or external. Internal students of the University are students who have matriculated at the University and who are pursuing a course of study approved by the University, either (*a*) under the direct control of the University or a committee appointed thereby; or (*b*) under one or more of the appointed or recognised teachers of the University. Centres for preliminary and intermediate medical studies have been established by the University at University and King's Colleges. Internal students must pursue their studies at one of the above centres, or at one of the medical schools connected with the University. These are St. Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Guy's Hospital, King's College Hospital, the London Hospital, St. Mary's Hospital, the Middlesex Hospital, St. Thomas's Hospital, University College Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. The London School of Tropical Medicine and the Lister Institute of Preventive Medicine are also recognised as schools of the University in special departments. External students are all other matriculated students, and may pursue their studies at other universities and medical schools, presenting themselves for examination at the University of London.

Faculty of Medicine.—The Faculty of Medicine grants the joint degrees of M.B., B.S. (*Bachelor of Medicine and Surgery*), and the higher separate degrees of M.D. (*Doctor of Medicine*) and M.S. (*Master of Surgery*).

The curriculum for the medical degrees is now five and a half years from the time of matriculation, except in the case of students who have passed the Preliminary Scientific Examination or the First Examination for Medical Degrees before July, 1910, and the examinations formerly known as the Preliminary Scientific, the Intermediate, and the Final Examination in Medicine are now respectively entitled the First, Second, and Third Examinations for Medical Degrees. Part II. of the former Preliminary Scientific Examination has now been made Part I. of the Second Examination.

A. *Internal Students.*—In order to be admitted to the Bachelor's degrees a student must normally, after registration as an internal student, have: (1) Attended prescribed courses of study for five and a half years in one or more schools of the University. (2) Passed the following examinations, under the conditions mentioned below: (*a*) The First Examination for Medical Degrees in Inorganic Chemistry, Physics, and General Biology; (*b*) the Second Examination for Medical Degrees: Part I., Organic and Applied Chemistry; Part II., Anatomy, Physiology, and Pharmacology, including Pharmacy and Materia Medica; (*c*) the Third Examination for Medical Degrees, or M.B., B.S. Examination in Medicine, including Therapeutics and Mental Diseases, Surgery, Midwifery and Diseases of Women, Pathology, Forensic Medicine and Hygiene.

B. *External Students.*—To be admitted to the Bachelor's degrees an external student must (1) have passed the Matriculation examination or have been exempted therefrom under Statute 116 not less than five and a half years previously; (2) have passed subsequent examinations similar to those required of an internal student; and (3) have been engaged in professional studies during the five and a half years subsequently to Matriculation and four and a half years subsequently to passing the First Examination for Professional Degrees at one or more of the medical institutions or schools recognised by this University for the purpose, one year at least of the four and a half years to have been spent in one or more of the recognised institutions or schools in the United Kingdom.

The First Examination for Medical Degrees (Inorganic Chemistry, Physics, and General Biology) will take place twice in each year, commencing on the Monday following Dec. 10th and on the second Monday in July. It must as a rule be passed by internal students not less than one academic year after matriculation and by external students not less than nine months after matriculation.

The Second Examination for Medical Degrees (Part I.): Organic Chemistry.—This examination will take place twice in each year, commencing on the Thursdays following the third Monday in March and the second Monday in July. No candidate will be admitted to this examination within six months of having passed the First Examination. [During the continuance of the war only this examination will be held in December as well as in March and July.]

The Second Examination for Medical Degrees (Part II.) takes place twice in every year, commencing on the third Monday in March and on the first Monday in July. The subjects of the examination are Human Anatomy and Embryology, Physiology, and Pharmacology, including Pharmacy and Materia Medica. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees.

The Third or M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the fourth Monday in October and on the first Monday in May. No candidate except those who pass the Preliminary Science or First Examination for Medical Degrees before July will be admitted to this examination within three academic years from the date of passing in Anatomy and Physiology at the Second Examination (Part II.), nor unless he has completed that examination together with prescribed courses of study or practice summarised below. (1) Principles and Practice of Medicine; (2) Clinical Methods and Physical Diagnosis; (3) Insanity (with clinical demonstrations at a recognised Asylum); (4) Therapeutics; (5) Vaccination; (6)

Principles and Practice of Surgery; (7) Operative Surgery, Surgical Anatomy, Practical Surgery, and the Administration of Anæsthetics; (8) Diseases of the Eye, Ear, and Throat; (9) Lectures and Demonstrations on Midwifery and Diseases of Women; (10) Practical Midwifery, the conduct of at least 20 Labours, and practice as a Clinical clerk in Gynæcological work; (11) Pathology and Bacteriology; (12) work of the Post-mortem room; (13) Forensic Medicine; and (14) Hygiene. He must also have attended the Medical and Surgical practice of a recognised hospital for two years and a course of instruction at a recognised Fever Hospital for two months.[1] He must have had clinical instruction and must have held the posts of medical clinical clerk and surgical dresser for periods of six months each. Candidates will be examined in Medicine (including Therapeutics and Mental Diseases), Pathology, Forensic Medicine and Hygiene, Surgery, Midwifery, and Diseases of Women. The subjects may be divided into two groups—namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Midwifery, and Diseases of Women. These groups may be taken either separately or together. The list of candidates who have passed will be published in two parts—namely, an Honours list and a Pass list. Bachelors of Medicine of this University who graduated in or before May, 1904, may obtain the B.S. degree by passing the Surgical part of the M.B., B.S. examination.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the first Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches, namely: (1) Medicine; (2) Pathology; (3) Mental Diseases; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Any candidate for the degree of M.D. may transmit to the Registrar a thesis or published work having definite relation to the branch of Medicine in which he is a candidate, and if the thesis be approved by the examiners the candidate may be exempted from the written examination in that subject.

Master in Surgery.—The examination for the degree of Master in Surgery takes place twice in each year and commences on the first Monday in December and on the first Monday in July.

Fees.—Matriculation £2 2*s.*, which will be returned if the candidate withdraws his name before the last day of entry. Should he fail to present himself an additional £1 1*s.* will be charged on subsequent presentation within eight months. £2 will be charged on each subsequent entry. At provincial examinations an additional fee of £1 1*s.* to £3 3*s.* is charged by the local authorities at the time of examination. First M.B., B.S. Examination: £5 5*s.* for each entry to the entire examination, or £2 2*s.* each subject if the examination is taken in parts. Second M.B., B.S. Examination: Part I. £2 2*s.*, repeated on each subsequent entry; Part II. £8 8*s.* for the whole examination. For re-examination in one subject £4 4*s.* Third (Final) M.B., B.S. Examination: £10 10*s.* for each entry to the whole examination and £5 5*s.* for examination or re-examination in each group. M.D. Examination: £21; for re-examination £10 10*s.* M.S. Examination: As for M.D.

Full details of the prescribed curricula of study and the names of the recognised Internal and External Schools of the University, can be obtained free on application to the Academic Registrar, University of London, South Kensington, S.W.

[1] During the continuance of the war students who have not passed the Second Examination for Medical Degrees in Anatomy and Physiology, but who have completed one year's study after passing the First Examination for Medical Degrees, will be allowed to count not more than six months' service as clinical clerk or not more than six months' service as surgical dresser in a recognised hospital as if they had so passed the examination in question. Clinical service during the continuance of the war, for any period of not more than twelve months in a medical Unit of the Regular or Territorial Forces, or in a hospital or detachment of the Red Cross Society, or in any hospital recognised by the military or naval authorities for war purposes, will be accepted by the University as equivalent to the medical and surgical practice in a recognised hospital for an equal period; and further, any portion or the whole of the time so spent will be accepted as equivalent to time spent either as a clinical clerk or as a dresser, at the choice of the candidate. Clinical service during the continuance of the war, as set forth above, will be similarly accepted for a period not exceeding six months from students who have not passed the Second Examination for Medical Degrees in Anatomy and Physiology, but who have completed one year of study after passing the First Examination for Medical Degrees, as if they had so passed the examination in question.

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON.[1]

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The hospital contains 757 beds, of which 687 are for patients in the hospital at Smithfield and 70 for convalescent patients at Swanley. It receives over 8000 in-patients annually and its out-patients and casualties amount to more than 75,000 annually. Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery, and for Electro-therapeutics and X Ray work. Surgical operations take place every day at 1.30 P.M. and Surgical Consultations are held on Thursdays at the same hour. Medical Consultations are held on Thursdays at 3.15 P.M. The physicians and surgeons deliver clinical lectures weekly during both the winter and the summer sessions. Clinical Lectures on all special subjects are also given. The visits of the physicians and surgeons are made at 1.30.

Ten house physicians and ten house surgeons are appointed annually, and are provided with rooms by the hospital authorities and receive £80 a year as salary. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Three resident anæsthetists are appointed annually, and receive salaries of £120, £100, and £100 respectively, with rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students. A residential college is attached to the hospital.

New Buildings.—The new buildings comprise residential quarters for the resident staff, casualty, medical, surgical, and special out-patient departments, casualty wards, dispensary, and clinical lecture theatre. A new chemical laboratory has been added to the Medical School, and a laboratory devoted to instruction in Public Health. A second new block is devoted to Pathology, and contains the post-mortem room as well as extensive laboratories for bacteriology, clinical pathology, pathological histology, and pathological chemistry. *The Medical School Buildings* include three large lecture theatres, a large dissecting room, a spacious library (containing 13,000 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The pathological museum is the most complete in the kingdom. There are laboratories for chemistry, physiology, pharmacology, physics, public health, and biology, giving ample accommodation in every department.

Special Classes for the Primary and Final F.R.C.S. are held twice yearly. *Instruction in Preliminary Science* is given to University of London students in chemistry, biology, and physics throughout the year. *Laboratory Instruction for the D.P.H.* is provided during the winter and summer sessions.

The recreation ground of 10 acres is at Winchmore Hill for the use of the members of the Students' Union, which all students are expected to join. The Students' Union contains a large reading and smoking room, a committee and writing room, luncheon and dining hall, and a miniature rifle range.

Scholarships given in aid of Medical Study.—At this school various Scholarships, prizes, &c., are given. For five of the Scholarships and the Exhibition—namely, (*a*), (*b*), two Entrance Scholarships of the respective values of £75 and £100; (*c*) Entrance Scholarship in Arts, £100; (*d*) Jeaffreson Exhibition, £50; and (*e*) Shuter Scholarship, £50—a full or University course at St. Bartholomew's Hospital is required. The awards of (*a*), and (*b*) are made after examination in selections from the subjects of Chemistry, Physics, Zoology, Botany, Physiology, and Anatomy; (*c*) and (*d*) are awarded after examination in Latin, Mathematics, and Greek or French or German; (*e*) is awarded after competitive examination among Cambridge Graduates in Anatomy and Physio-

[1] For Ancillary Metropolitan Medical Schools see p. 280.

logy. The remaining Scholarships and prizes are as follows:—Four Junior Scholarships: (*f*) No. 1, £30, Anatomy and Physiology; (*g*) No. 2, £20, Anatomy and Physiology; (*h*) No. 3, £25, Chemistry, Physics, and Biology; (*i*) No. 4, £15, Chemistry, Physics, and Biology; (*j*) Senior Scholarship, £50, Anatomy, Physiology, and Chemistry; (*k*) Kirkes Scholarship, £30 and medal, Clinical Medicine; (*l*) and (*m*) two Brackenbury Scholarships, £39 each, one in Medicine and one in Surgery; (*n*) Sir G. Burrows Prize, £10, Pathology; (*o*) Skynner Prize, 13 guineas, Regional and Morbid Anatomy; (*p*) Matthews Duncan Medal and Prize, £20, Midwifery and Gynæcology; (*q*) Luther Holden Research Scholarship in Surgery, awarded by election, £105; and (*r*) Lawrence Research Scholarship and gold medal in Pathology, awarded by election, £115.

Information may be obtained on application to the Dean of the Medical School: Dr. T. W. Shore. The Warden of the College is Mr. W. Girling Ball.

CHARING CROSS HOSPITAL.—The Hospital, to which the School is attached, contains 300 beds. Over 3000 cases pass through its wards each year, and some 24,000 out-patients and casualties are treated. There are special departments for Mental Diseases, Midwifery, Diseases of Women, of Children, of the Skin, Eye, Ear, Throat, Nose, and Teeth, for Orthopædic Cases, X Ray work, and for Electrical Examination and Treatment.

Appointments.—In the Medical School Demonstratorships and Assistant Demonstratorships are open to students of the School. Medical, Surgical, and Obstetric Registrars to the Hospital are appointed annually. Six House Physicians, six House Surgeons, and two Resident Obstetric Officers are appointed each year after competitive examination.

Primary and Intermediate Studies.—By an agreement with the University of London the School sends its Primary and Intermediate Students to receive their lectures and practical work at King's College, which is situated within four minutes' walk. This arrangement has proved most successful.

Final Studies.—These are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for qualifying examinations. Departments are also available for other final subjects of Bacteriology, Clinical Pathology, Materia Medica, Toxicology, Public Health, and Operative Surgery, and also for Research Work and Post-graduate Work.

The *Museum* contains over 4000 specimens, including a notable collection of over 800 gynæcological specimens, "The Cuthbert Lockyer Collection."

Students' Club.—The social comfort and convenience of students are met by library, reading, and smoking-rooms, refreshment-room, &c. The Club, which is under the control of a Committee of Students, provides needful athletic recreation, and includes the Medical Society.

Women Students.—Women students are accepted by the School and Hospital upon the same terms and conditions as men, and after qualification are eligible for resident Hospital appointments. A separate common-room and a female attendant are provided, but beyond this no further distinction is made. This system of co-education, under which men and women are placed on terms of complete equality throughout the whole of the curriculum, has been found to work successfully and to their mutual advantage.

Fees.—An entrance fee of 10 guineas and 8 guineas is payable by full-course and final-course students respectively, and an annual fee of 26 guineas covers all other expenditure, with the exception of 7 guineas for vaccination, dispensing, and fever hospital attendance, which must be taken outside the hospital. Membership of the Students' Club is included in these fees.

Further information may be obtained on application to the Dean, Dr. W. J. Fenton, Medical School, Charing Cross Hospital, London, W.C.

ST. GEORGE'S HOSPITAL.—This hospital has a service of 436 beds, of which 180 are allotted to surgical, 150 to medical cases, and 100 are at the Convalescent Hospital at Wimbledon. One ward is set apart for Diseases Peculiar to Women. Children's beds are placed in all the women's wards. Two wards are allotted to ophthalmic cases.

Entrance Scholarships and Endowed Prizes of a total value of £482 are awarded annually; a detailed list is placed below. The entire teaching and laboratories are now devoted to purely clinical subjects, and arrangements have been made with the University of London for students who enter during the first, second, or third year of the curriculum as students of St. George's to carry out the necessary courses of instruction at either University College or King's College. Students then complete their course, without payment of any entrance fee, in a school entirely devoted to Clinical work. The school is admitting a strictly limited number of women students during the war. These women students will be allowed to continue their studies until qualification.

Eight house physicians and eight house surgeons are appointed annually. Special attention is directed to the following paid appointments, among others, which are open to students after they have held house office:—Medical Registrarship at £200 per annum; Surgical Registrarship at £200; Assistant Curatorship of the Museum at £100; Obstetric Assistantship (Resident) at £50; the post of Resident Anæsthetist at £100; the post of Senior Anæsthetist at £50; the posts (3) of Junior Anæsthetists, each at £30. The St. George's Hospital Club, with smoking- and luncheon-rooms on the hospital premises, and an athletic ground at Wimbledon, is an amalgamation of the Hunterian Society, the *Gazette*, and the chess, lawn tennis, boxing, hockey, rifle, and golf clubs. Students have the advantage of a library of medical and scientific books which is kept up-to-date.

Scholarships and Prizes.—At this school two entrance scholarships are given, the money value and the subjects of examination being as follows: (*a*) and (*b*) two University Entrance Scholarships, 70 guineas and £50 respectively, Anatomy and Physiology. The others are as follows: (*c*) William Brown Exhibition, tenable for two years and open to perpetual pupils having registrable qualifications, £112 per annum, Practice of Medicine, Midwifery, and Surgery; (*d*) William Brown Exhibition, tenable for three years and open to perpetual pupils qualified not more than three years previously, £42 per annum, Essay and Original Work; (*e*) Allingham Scholarship in Surgery for Students qualified not more than three years, £50, Competitive Essay; (*f*) and (*g*) two Brackenbury Prizes, one in Medicine and one in Surgery, £30 each, open to students of not more than five years' standing; (*h*) H. C. Johnson Memorial Prize, £15, Practical Anatomy; (*i*) Pollock Prize, £17, Physiology, Physiological Chemistry, and Histology; (*j*) Clarke Prize, £5; (*k*) Thompson Medal, £5, Clinical Reports; (*l*) Brodie Prize, £7, Clinical Reports; (*m*) Webb Prize, open to perpetual pupils, £30, Bacteriology.

Further information may be obtained from the Acting Dean of the Medical School, Mr. R. R. James.

GUY'S HOSPITAL.—This hospital, founded by Thomas Guy in 1721 for the reception of 400 patients, and enlarged through the aid of a large bequest from the late William Hunt, contains at the present time 643 beds. The school buildings have been rebuilt and now offer very complete accommodation. Within the grounds of the hospital are situated the residential college, with accommodation for 60 students, the students' club, with reading, smoking, luncheon, and dining-rooms, a fives court, and swimming bath. The athletic ground and club house is situated at Honor Oak Park, and can be reached in 20 minutes from the hospital.

House physicians, house surgeons, out-patient officers and assistant house surgeons, obstetric residents, ophthalmic house surgeons, clinical assistants, clerks to anæsthetists, surgeons' and assistant surgeons' dressers, surgical and medical clinical clerks, post-mortem clerks, extern obstetric attendants, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the medical council according to merit.

There is a Medical Section of the Officers' Training Corps of the University of London in connexion with the Hospital. Drill is held in the grounds of the Hospital, so that the senior students can carry out the necessary military training without any serious interruption of their work in the wards. The establishment of a Venereal Clinic, in accordance with the Scheme of the Local Government Board and London County Council. Lectures and clinical instruction are given,

to which Medical Students and Practitioners are admitted without fee. Residential College: the rent of rooms remains the same, but the cost of board has increased.

Scholarships.—Five entrance scholarships are awarded annually as follows:—(*a*) one scholarship of £100 for students under 21 years of age, Latin, English, Greek or French or German, Arithmetic, Euclid, and Algebra; (*b*) one scholarship for students under 21 years, £120, Inorganic Chemistry, Physics, and Biology; (*c*) a Scholarship of £50, open to candidates under 21 years of age, to be awarded either in Arts or in Science, according to the discretion of the Examiners, and to the percentage of the marks obtained; (*d*) two scholarships, one of £75 and one of £35, for students under 25 years of age who have completed the curriculum for, or passed the examination in, Anatomy and Physiology for a medical degree in any University of the British Empire. Subjects: Any two of the following: Anatomy, Physiology, Pharmacology, General Pathology, Organic Chemistry.

In agreement with the practice of the Universities, an allowance will be made (1) for Military Service performed by candidates, the term "military service" meaning service in the Naval or Military Forces of His Majesty or of His Majesty's Allies during the present War; or (2) in respect of other approved duties in connexion with national defence.

The Honorary Dean of the Medical School is Sir Cooper Perry, the Sub-Dean Dr. M. S. Pembrey, from whom further information may be obtained.

UNIVERSITY OF LONDON: KING'S COLLEGE.—The medical department (Faculty of Science, Medical Division) at this College only deals with Preliminary and Intermediate subjects, and instruction in these subjects is given in the College laboratories by university professors and their assistants. The following four hospital schools prepare their students only for the final examinations—viz., King's College Hospital, Westminster Hospital, St. George's Hospital, and Charing Cross Hospital—sending them to King's College for the earlier part of the curriculum. The department is open to both men and women.

Fees.—For London University course: For First examination for medical degrees, 25 guineas; for the Second examination, 58 guineas, or two instalments of 30 guineas each. For Conjoint Board course: For First examination, 20 guineas; for Second examination, 58 guineas, or two instalments of 30 guineas each. For prospectus and further information application should be made to the Dean of the department (Professor W. D. Halliburton).

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.—The advanced subjects in the curriculum are dealt with at the Medical School attached to King's College Hospital, which is situated at Denmark Hill, S.E. The hospital stands in the midst of a South London population, from which an immense amount of clinical material is forthcoming, an average of 3500 out-patients being dealt with weekly. There are 350 beds available for in-patients, and provision will ultimately be made for 600 beds. Special departments are provided for the following: diseases of women and children, the eye, ear, throat and nose, skin, teeth; radiography, radiotherapy and radium-therapy; pathology, massage, medical gymnastics, and electro-therapeutics. The appointments open to students are those of senior clinical assistant to the special departments; medical, surgical, and obstetric tutorships; resident casualty officer; resident anæsthetist; resident assistant pathologist; and medical, surgical, and obstetric registrarships. There are 16 resident medical and surgical officers appointed yearly.

Scholarships and Prizes.—For the first two scholarships in the list here shown a complete course at King's College is required. The money value and subjects of examination are as follows:—(*a*) Two Warneford Scholarships, tenable for four years, £25 each per annum; (*b*) Sambrooke Scholarship, £50; (*c*) Rabbeth Scholarship, £20; (*d*) Medical Entrance Scholarships, £50, Anatomy and Physiology, and, £50, Pathology and Pharmacology, open to students who (1) propose to take a degree at any British University, and have passed their University examination in Biology, Chemistry, and Physics, and who (2) will become students at King's College Hospital from date of entering upon Scholarship; (*e*) Two Medical Entrance Scholarships one in Arts and one in Science, £50 each, tenable for five years, successful candidates to study at King's College and King's College Hospital; (*f*) Three Medical Scholarships, £40 for fifth-year students, £20 for third-year students, and £20 for second-year students; (*g*) Two Sambrooke Registrarships, open to matriculated students who have filled certain appointments in hospital, £50 each; (*h*) Carter Prize, £15, Botany; (*i*) Tanner Prize, £10, Obstetrics and Diseases of Women; (*j*) Todd Prize, £4 4*s*. and medal, Clinical Medicine; (*k*) Two Burney Yeo Entrance Scholarships, £80 each, open to students of Oxford and Cambridge.

Athletics.—The King's College Hospital Clubs and Societies Union was formed in 1908, and consists of the Listerian and Musical Societies, the Hospital Common Room, and the various athletic and sports clubs. Admirable playing fields, over six acres in extent, have been provided for the use of the students on Dog Kennel Hill, Lordship-lane, S.E., about ten minutes' walk from the hospital. There are also Tennis Courts in the grounds of the Hospital and of "The Platanes," the hall of residence for students belonging to the hospital.

Fees.—The composition fee for Hospital work and Final subjects of the curriculum is 70 guineas if paid in one sum, or 72 guineas if paid in two instalments. For information and prospectus application should be made to Dr. H. W. Lyle, Dean of the Hospital, or to Mr. S. C. Ranner, M.A., Secretary of the Medical School, Denmark Hill, S.E. 5.

LONDON HOSPITAL.—The hospital has 933 beds in constant use and no beds are closed. It is the only general hospital for East London—i.e., for a million and a half people. In-patients last year, 16,053; out-patients, 102,130; major operations, 6656. From the beginning of the war to the close of 1917 4771 military patients were admitted, while naval patients (who were first admitted at the end of September) totalled 396. In the wards (containing 15 beds) provided for the treatment of syphilis 758 patients were admitted for treatment during 1917. Owing to the large number of patients more appointments are open to students than at any other hospital. 141 qualified appointments are made annually and more than 150 dressers, clinical clerks, &c., appointed every three months. All are free to students of the College. Holders of resident appointments have free board. Special classes are held for the degrees of the University of London, the Fellowship of the Royal College of Surgeons, and other higher examinations. Special entries for medical and surgical practice can be made. The Students' Hostel provides accommodation for 30 students. The Clubs Union Athletic Ground is within easy reach of the hospital. The Metropolitan and other railways have stations close to the hospital and the college.

Scholarships and Prizes.—At this school the successful candidates for the first items in the list here shown must enter as full students. The value and the subjects of examination are as follows:—Price Scholarship £100; and one Entrance Scholarship of £50, subjects of First Medical Examination at the University of London; Epsom College Scholarship, free education, subjects of First Medical Examination as above; Price Scholarship, open to students of Oxford and Cambridge Universities, £52 10*s*., Human Anatomy and Physiology; Buxton Scholarship, £31 10*s*., subjects of Preliminary Examination in Arts; three Scholarships for Clinical Work, £20 each, Medicine, Surgery, and Obstetrics; Sutton Prize, £20, Pathology; Duckworth Nelson Prize, biennial, £10, Pathology, Practical Medicine, and Surgery; Letheby Prizes (2), £25, Chemistry; £25 in Anatomy and Physiology; eight Dressers' Prizes, amounting to £40, zeal, efficiency, and knowledge of Elementary Clinical and Minor Surgery; Hutchinson Prize, triennial, £40, Clinical Surgery; two Practical Anatomy Prizes, £6 and £4 respectively; Andrew Clark Prize, biennial, £26, Clinical Medicine and Pathology; James Anderson Prizes, £9, Elementary Clinical Medicine; Wynne Baxter Prize, £5 5*s*., Forensic Medicine; Arnold Thompson Prize, £5; and Liddle Prize, triennial £120.

Medical Research Funds.—Research Funds of over £25,000, including the Eliza Ann Alston Endowment Fund for Medical Research, provide valuable scholarships for men wishing to undertake research or desirous of preparing Theses for University degrees.

The above arrangements are subject to revision in consequence of circumstances arising out of the war.

Further information may be obtained from the Dean of the Medical School, Professor Wm. Wright, or from the Secretary of the College, Mr. E. J. Burdon.

ST. MARY'S HOSPITAL.—305 beds. The number of in-patients treated during 1917 was 2861. The number of out-patients was 12,512 with 17,794 casualty cases, a total of 30,306. The situation of the hospital and Medical School in the centre of the residential districts of Paddington, Bayswater, and North Kensington renders it exceptionally convenient for students' rooms, a register of which is kept by the authorities for the use of students.

Laboratories, &c.—The Medical School provides for the entire curriculum. Special laboratories are in use for Biology, Chemistry, and Physics, a series of lecture theatres and laboratories for Anatomy and Physiology, and a spacious and well-lighted dissecting-room. The Pathological Department is under the direction of Dr. B. H. Spilsbury, and a block of consulting-rooms and laboratories in the New Wing of the Hospital has been equipped for the department of Therapeutic Inoculation.

Appointments.—All clinical appointments in the hospital are free to students of the Medical School and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, four obstetric officers are appointed in each year and receive board and lodging in the hospital. Two resident anæsthetists are appointed in each year and receive a salary at the rate of £100 per annum, with board and lodging. Four casualty house surgeons are appointed in each year upon the same conditions. Several assistants in the department of Therapeutic Inoculation are appointed annually at salaries of £100 per annum and upwards. In addition to the above, the senior appointments, medical, surgical, and obstetric registrar, casualty physician, demonstrator of anatomy, physiology, and biology are made annually.

Clubs, &c.—The amalgamated clubs include all the various athletic clubs, as well as the medical society, &c. There is a students' club on the Hospital premises, the membership of which is included in the amalgamated clubs. The athletic clubs' ground at Park Royal, Acton, has been commandeered by the War Office and sold. Steps are now being taken to procure a new site.

Special Tuition.—Special tuition is provided for the Intermediate and Final Examinations of the Universities of Oxford, Cambridge, and London, and for the Primary and Final F.R.C.S.

The composition fee for full students is £140 if paid in one sum, or £145 if paid in four instalments. University students who have completed their examinations in Anatomy and Physiology are admitted on payment of a composition fee of 65 guineas (£68 5*s.*) paid in one sum or by payment of two annual instalments of 40 guineas (£42) and 30 guineas (£31 10*s.*) respectively. A system of annual fees is also in force as an alternative to composition fees. Separate courses of lectures, laboratory work, or hospital practice may be taken.

Scholarships and Prizes.—The money value and subjects of examination of these are as follows: (*a*) and (*b*) Entrance Scholarships in Natural Science, £100 and £50 respectively, awarded by competition in September; (*c*) the Frederic John Palmer Scholarship in Natural Science, £25; (*d*) University Scholarship in Natural Science, open to members of Oxford or Cambridge University, £52 10*s.*; (*e*) University Scholarship in Natural Science, open to members of any British University, £52 10*s.*; (*f*) Epsom Scholarship, awarded by nomination, £52 10*s.*; (*g*) Gold Medal, £20, an Essay on Some Special Point in Clinical Medicine; (*h*) Meadows' Prize, awarded in alternate years, £8, Obstetrics; (*i*) Wallace Memorial Prize and Medal, for work in Vaccine Therapy, £5 5*s.* David Lees Prize in Clinical Medicine, £8.

Sir John Broadbent is Dean of the Medical School. The School Calendar and full information can be obtained from the Secretary, Mr. B. E. Matthews, St. Mary's Hospital Medical School, Paddington, W.

MIDDLESEX HOSPITAL.—The Hospital and Medical School are situated in Mortimer-street, at the top of Berners-street, and only a few minutes' walk from Goodge-street Station (Hampstead and Charing Cross Tube), Oxford Circus Stations (Bakerloo and Central London Tubes), and Great Portland-street Station (Metropolitan Railway).

The hospital contains 455 beds, including special wards for Cancer Cases, Maternity and Gynæcological Cases, and for Diseases of Children and the Skin and Eye.

The Cancer Charity, containing 92 beds and Special Investigation Laboratories, offers unrivalled opportunities for the study of Cancer, both in its clinical and pathological aspects.

In the Electro-Therapeutical Department students obtain instruction in the Treatment of Lupus and Cancer by the X Ray method of treatment. An Electrocardiograph Department has recently been established.

The Hospital and Medical School are fully equipped for the theoretical and practical teaching of all the subjects of the medical curriculum, and for the Diplomas in Public Health. Ample laboratory and class-room accommodation is provided.

The Bland-Sutton Institute of Pathology contains a new lecture theatre and large pathological, bacteriological, and clinical laboratories where every facility is given for original research. The Anatomical and Pathological Museum is now part of the Institute. Special classes are held to prepare students for the Intermediate examinations of the Universities, and for the Primary and Final examinations for the F.R.C.S. (England) Diploma. There is a Residential College in the hospital for students.

Hospital Appointments.—All appointments are made without fee of any kind, and the following are appointed at intervals annually: six house physicians, eight house surgeons, two obstetric and gynæcological house surgeons, two casualty medical officers, two casualty surgical officers, one resident anæsthetist, and two resident officers to the special departments. The medical and surgical casualty officers are appointed twice a year. The medical, surgical, and obstetric and gynæcological registrars are appointed as vacancies arise.

Non-resident qualified clinical assistants are appointed to assist in the various out-patient departments. Clinical clerks and surgical dressers are also appointed in every department.

Scholarships, Prizes, &c.—(*a*), (*b*), and (*c*) Three Entrance Scholarships, value £100, £50, and £25, and (*d*) a University Scholarship, value £50, are awarded annually in September. The successful candidates are required to become general students of the school. (*e*) A Freer Lucas Scholarship for Students of Epsom College is awarded annually on the nomination of the Headmaster. There are also, (*f*) and (*g*), two Broderip Scholarships, value £60 and £40 respectively; (*h*) the Lyell Gold Medal and Scholarship, value £55 5*s.*; (*i*) the John Murray Medal and Scholarship, value £25 (awarded every third year); (*k*) the Freeman Scholarship, value £30; (*l*) the Hetley Clinical Prize, value £25; (*m*) the Leopold Hudson Prize, value 11 guineas; and (*n*) the Second Year's Exhibition, value 10 guineas. There are also numerous class prize examinations.[2]

In connexion with the Cancer Investigation Department the following Scholarships are awarded:—Richard Hollins Research Scholarship, value £100; Walter Emden Scholarship, value £100; and a Cancer Research Scholarship, value £60.

Fees.—The Composition Fee for the curriculum for the diplomas of the Conjoint Board or Society of Apothecaries is 135 guineas; for the curriculum for the degrees of the University of London 145 guineas; for students who have passed the First Examination for Medical Degrees (University of London), 120 guineas; and for those who have completed their Anatomical and Physiological studies, 70 guineas. The fee for Dental students is 54 guineas. The fees may be paid by instalments.

The Amalgamated Students' Club includes the following: the Medical Society, the Common Room Society, the cricket club, the football clubs, the athletic club, the rowing club, the musical society, the chess club, the lawn tennis club, and the hockey club. A subscription to the Amalgamated Students' Club is payable by all General and Dental students.

ST. THOMAS'S HOSPITAL.—This hospital received its present charter from King Edward VI., but as a monastic institution was in existence prior to the year 1207. The building occupies a unique position by the river, opposite the Houses of Parliament, and contains 1014 beds, including

[2] Certain of these scholarships and those in connexion with the Cancer Investigation Department have been modified for the period of the war, particulars of which can be obtained on application.

530 for military patients. The in-patients last year numbered 9780, whilst the number of attendances as out-patients, including the casualty and light departments, was 242,686. There are special departments for the treatment of women, children, the eye, ear, nose and throat, skin, and teeth. The Tuberculosis Department forms a part of the Lambeth scheme for treatment of patients and for instruction. The Venereal Department has been established as part of the London County Council scheme. Departments for light treatment. X rays, and the Physico-therapeutic Department are also special features. A speech clinic has recently been inaugurated in connexion with the Children's Department. Exceptional facilities are offered in the hospital laboratories for the study of general pathology, clinical pathology, chemical pathology, cardiology, and of treatment by serums and vaccines. Surgical operations take place in the main theatres every day except Saturdays at 2 P.M. Clinical teaching in the wards, out-patients' and special departments, is available every day of the week. Clinical lectures are delivered every Wednesday during the sessions. All appointments in the hospital are open to students without extra fee. Clinical assistants to all the special departments are appointed every three months. A resident assistant physician and a resident assistant surgeon, at a salary of £150 each, are appointed biennially; also four hospital registrars (medical, surgical, obstetric, and ophthalmic), the two former receive a salary of £150 and the two latter £50. An assistant in the clinical laboratory and an assistant pathologist are paid at the rate of £200 per annum. Appointments open to students before qualification: Clinical clerks and dressers for in- and out-patients are selected from students who have completed their third year's work. Every student acts as clerk in the post-mortem room and in one of the pathological laboratories, takes his turn on maternity duty under proper supervision in the maternity ward, thus obviating any necessity for seeking instruction elsewhere. Students are instructed in the administration of anæsthetics by one of the hospital anæsthetists. The Students' Club comprises a spacious restaurant and smoking and reading room. There is no occasion for students to leave the hospital buildings during working hours. The curriculum is arranged to meet the requirements of all the Examining Bodies. Special classes are held for the examinations at the University of London and for the First and Final Fellowship Examinations of the Royal College of Surgeons of England. Tutorial classes in all subjects precede the various examinations. The hospital is easily accessible from all parts.

Fees.—The annual composition fee is 30 guineas, covering all tutorial classes—in addition to a fee on entrance. Qualified practitioners are permitted to attend the hospital practice on terms which may be ascertained from the secretary.

Scholarships and Prizes.—At this school there are five Entrance Scholarships—namely, two in Arts, equivalent to the tuition fees for the first medical examination; two in Natural Science, of the value of £150 and £60 respectively, to be taken out in tuition fees; and the University Scholarship of £50 in Anatomy, Physiology, and Chemistry. The money value and subjects of examination of the remainder are as follows: (*a*) and (*b*) two College Prizes, one for second-year students and one for third-year students, £10 and £5 respectively; (*c*) William Tite Scholarship for second-year students, £25; (*d*) and (*e*) Musgrove Scholarship or (alternately) Peacock Scholarship, each for third-year students and tenable for two years, £35 each; (*f*) three College Prizes for fifth-year students of £10 each and three of £5 each; (*g*) Cheselden Medal, Surgery and Anatomy; (*h*) Mead Medal, Medicine, Pathology, and Hygiene; (*i*) Toller Prize, Medicine, Pathology, and Hygiene; (*j*) Bristowe Medal, Pathology and Morbid Anatomy: (*k*) Solly Medal and Prize, biennially, Surgical Reports; (*l*) Treasurer's Gold Medal for the most distinguished fifth-year student; (*m*) Wainwright Prize, Medicine, Pathology, and Hygiene: (*n*) Hadden Prize, Pathology; (*o*) Beaney Scholarship, £50 biennially, Surgery and Surgical Pathology; (*p*) Sutton Sams Prize, biennially, reports of cases in Obstetric Medicine; (*q*) Grainger Testimonial Prize, £31 10*s*. Anatomy and Physiology; (*r*) Salters' Company Research Fellowship, tenable for three years, £100 annually, Pharmacology; (*s*) Louis Jenner Research Scholarship, tenable for two years, £60 annually, Pathology; and (*t*) Research Scholarship, tenable for two years, £200 per annum.

The Dean of the Medical School is Dr. E. Stainer, the Sub-Dean Dr. C. R. Box, and the Secretary Mr. G. Q. Roberts, from whom any further information may be obtained.

UNIVERSITY OF LONDON, UNIVERSITY COLLEGE.—University College has been constituted a University centre for the teaching of medical sciences. The College Faculty of Medical Sciences comprises the Departments of Physics, Chemistry, Botany, and Zoology (the Preliminary Medical Sciences); also the Departments of Anatomy, Physiology, and Pharmacology (the Intermediate Medical Sciences), and the Departments of Hygiene and Public Health, and of Pathological Chemistry (Post-graduate Study).

Faculty of Medical Sciences.—Composition fees.—For the courses required by the University of London. 1. For the First Medical Course, 26 guineas, entitling to one attendance and to the privileges of the Union Society for one session. 2. For the Second Medical (Intermediate) Course, 58 guineas if paid in one sum; 60 guineas if paid in two instalments of 30 guineas each. This fee entitles to attendance at Anatomy and Physiology during three years and to one attendance at Organic and Applied Chemistry, Pharmacology, and Materia Medica, and to the privileges of the Union Society for two sessions.

For the medical education required by the Examining Board in England and the Society of Apothecaries. First examination, Parts I., II., III., 21 guineas, entitling to attendance for the First and Second Terms and to the privileges of the Union Society for one session; 26 guineas, entitling to attendance throughout the session and to the privileges of the Union Society for one session. First Examination, Part IV., and second examination, 58 guineas if paid in one sum, and 60 guineas if paid in two instalments of 30 guineas each. This fee entitles to attendance during three years in all subjects but Practical Pharmacy and to the privileges of the Union Society for two sessions.

Scholarships and Prizes.—The first three items on the present list require a complete intermediate course at University College. The money value and subjects at examinations are as follows: (*a*) The Bucknill Scholarship, 135 guineas; (*b*) and (*c*) two Entrance Exhibitions, 55 guineas each, Chemistry, Physics, Botany, and Zoology; (*d*) Cluff Memorial Prize, £15 biennially, Anatomy, Physiology, and Chemistry; (*e*) Schäfer Prize in Physiology, £18 triennially; (*f*) Sharpey Physiological Scholarship, £105, Biological Sciences; (*g*) Morris Bursary for sons of deceased professional men, by nomination, tenable for two years, £16 a year; and (*h*) five Gold* and five Silver Medals* awarded annually in various departments.

Women students are admitted.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.—Dean: Dr. G. F. Blacker. Acting Secretary: G. E. Adams. It has been decided† to admit women as Medical Students to this Hospital and Medical School on and after Oct. 1st, 1918. They will now be able to pursue the whole of their Medical Education at University College and University College Hospital, and will be eligible for all Scholarships, Exhibitions, and Prizes, at the Medical School. Fees for Preliminary and Intermediate Course: See under University College. For the Final M.B., B.S. (London) Course, 80 guineas if paid in one sum, 82 guineas if paid in two instalments, as follows—first year, 50 guineas; second year, 32 guineas. This fee entitles to attendance on Lectures and Hospital Practice during three years and to one attendance on Practical Pathology and Practical Surgery. Vaccination and attendance at a Fever Hospital are not included. Students who obtain a medical qualification within three years of the time of commencing this course are not required to pay an additional fee for further attendance. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, and Durham, and for the medical education required by the Examining Board in England and the Society of Apothecaries.

There are over 400 beds in the hospital.

* Award suspended during the war.

† See THE LANCET, August 10th, 1918, p. 190.

Special Departments, Clinical and Laboratory Facilities.—Those who are desirous of carrying out original research in Pathology, including Morbid Anatomy, Bacteriology, Experimental Pathology, and Chemical Pathology, are admitted to work in the laboratories of the school by the Director of Pathological Studies and Research, and under certain conditions can receive grants from the Charles Graham Medical Research Fund. A special course of instruction is given for preparation for the examinations for Diplomas in Public Health of the various universities and examining bodies; also special courses of Lectures and Demonstrations in Anæsthetics, Diseases of the Eye, Ear, Nose, and Throat, Skin, and Diseases of the Teeth, in Electrical and Radioscopic Diagnosis and Treatment, in Clinical and Tropical Pathology, and in Cardiac Pathology. These courses are designed for senior students and graduates. Special arrangements have been entered upon which, when completed, will enable students of University College Hospital to carry out a portion of their clinical studies at the National Hospital for Nervous Diseases, Queen-square, the Children's Hospital, Great Ormond-street, and the Central London Ophthalmic Hospital, Judd-street. The Royal Ear Hospital, Dean-street, Soho, has been amalgamated with University College Hospital as the Ear, Nose and Throat Department. In the Dental Department in Great Portland-street, formerly known as the National Dental Hospital, there is afforded the opportunity for attending lectures and practical instruction in diseases of the mouth and teeth.

Appointments tenable by Students.—Clerkships and dresserships to the physicians, surgeons, anæsthetist, and pathologist are allotted amongst the students of the hospital. Maternity students are appointed each month and reside in the Students' House connected with the Medical School and Hospital. Eight house physicians and house surgeons, four senior and four junior obstetric assistants, are selected annually by examination from among the senior students who have a medical qualification. The house physicians and house surgeons reside free in the hospital for six months, and the senior obstetric assistants for three months. In addition to these posts there are certain special appointments which are vacant from time to time and are filled by senior students of the hospital: 1. The Resident Medical Officer. This officer is appointed for a period of two years and is chosen from amongst the more senior recent residents of the hospital. 2. The two Surgical Registrars are also chosen from among the more senior recent residents of the hospital. 3. The Obstetric Registrar. 4. Two Casualty Medical Officers and a Casualty Surgical Officer are appointed, each for a period of six months. 5. Assistant in Ear and Throat Department, appointed for one year. 6. Assistant in Ophthalmic Department, appointed for one year. 7. Registrar in Anæsthetic Department, appointed for one year. 8. Deputy Anæsthetists. During the absence of one or another of the Anæsthetists in the summer months a senior qualified student is appointed as a substitute and is granted a special certificate.

Museum of Pathological Anatomy.—The Museum, a spacious and well-lighted room, is open for study from 9 A.M. to 5 P.M. Microscopic sections of most of the specimens in the Museum have been prepared and are available for the use of students on application to the Curator. The Museum contains 1100 admirable paintings by Sir Robert Carswell and Sir Charles Bell and a collection of old surgical instruments formerly belonging to Robert Liston.

The Anatomical Museum of the University of London, University College, is open to all students of University College Hospital and Medical School on the recommendation of the School Committee.

The Medical Library is open daily for the purposes of study to every student of the Medical School from 9 A.M. to 5 P.M., Saturdays 9 A.M. to 1 P.M. It contains about 13,500 works on medical subjects, including all the current text-books and works of reference required for study or research.

The Medical Society of University College Hospital Medical School exists for the dual purpose (1) of promoting the study of Medical and Surgical Science, and (2) of promoting social intercourse among its members. All Students of the Medical School are eligible for membership. Meetings are held once a fortnight for the purpose of discussing subjects connected with the study of medicine. In its social aspect the society includes various athletic clubs and superintends the gymnasium and squash racquet court in the Medical School. The Athletic Ground, which is used in conjunction with the Union Society of the University of London University College, is situated near the Great Western Railway station at Perivale.

Scholarships and Prizes.—At this School the first two Scholarships (*a*) and (*b*) require a complete course at University College and University College Hospital Medical School; the second two (*c*) and (*d*) require a final course at the Medical School. The money value and subjects of examination are as follows:—(*a*) Entrance Scholarship, Bucknill, 135 guineas, Chemistry, Physics, Botany, and Zoology; (*b*) Epsom Free Medical Scholarship, subjects of Preliminary Scientific Examination and Nomination by Epsom College; (*c*) and (*d*) two Goldsmid Entrance Exhibitions, 80 guineas each, Anatomy and Physiology; (*e*) Graham Scholarship in Pathology, £200 per annum for two years, awarded by the Senate of the University of London; (*f*) Atkinson Morley Scholarship, tenable for three years, £45 per annum, Surgery; (*g*) Atchison Scholarship, tenable for two years, £55 per annum; General Proficiency in Medical Studies: (*h*) Magrath Clinical Scholarship, about £100, Clinical Cases; (*i*) Percival Alleyn Scholarship, about £60, Surgery; (*j*) Filliter Exhibition, £30, Pathology; (*k*) Erichsen Prize, £10 10*s*., Practical Surgery; (*l*) two Senior and two Junior Fellowes Clinical Medals for Clinical Medicine; (*m*) two Liston Gold Medals for Clinical Surgery; (*n*) Alexander Bruce Gold Medal for Pathology and Surgery; and (*o*) Tuke Silver and Bronze Medals for Pathology. (*p*) Radcliffe Crocker Travelling Scholarship for Dermatology.

Residence of Students.—University College Hall, Ealing, is recognised by the Medical School authorities as a residential hostel. The Students' House in University-street contains large and comfortable rooms. The Maternity Students occupy them on payment of a moderate charge. Gentlemen who desire assistance in their studies should consult the Dean or Lecturers.

WESTMINSTER HOSPITAL.—The hospital contains 215 beds and affords relief to upwards of 2000 in-patients and 30,000 out-patients annually. There are separate departments for Diseases of the Eye, Ear, Skin, Teeth, and Throat, for Orthopædic practice, for Diseases of Women, for Diseases of Children, for Radiography, and for the Light Treatment. The Anatomical, Pathological, and Materia Medica Museums are open to all students of the school.

The usual registrarships and house appointments will be made at the conclusion of the war.

By a scheme for the concentration of the teaching of the preliminary and intermediate subjects of the curriculum, which has the support of the London University, an arrangement has been made by the Westminster School for the teaching of these subjects at King's College. Students, however, join the Westminster Medical School as formerly and may compete for Entrance Scholarships as heretofore.

Scholarships and Prizes.—The following Entrance Scholarships are offered for competition: Winter Session: (*a*) Arts Scholarship, the "Guthrie," £60. (*b*) Science Scholarships: Natural Science Scholarship, £60; Chemistry and Physics Scholarship, £30; and Two Scholarships in Anatomy and Physiology, £50 each. Summer Session: Two Scholarships in Anatomy and Physiology, £50 each. During the period of study the following prizes may be competed for: Sturges Prize in Clinical Medicine, about £6, Notes of Cases; Clinical Surgery Prize, £5, Notes of Cases; Chadwick Prize £21 in books or instruments, Medicine and Surgery, including Pathology and Applied Anatomy and Physiology; Frederic Bird Medal and Prize, open to Fourth-year Students, £14 in medal and books or instruments—Midwifery, Diseases of Women, Medicine, Pathology, Forensic Medicine and Bacteriology, and Public Health and Toxicology; Abrahams Prize in Clinical Pathology, 5 guineas, a Paper and Tests in Practical Work; Alfred Hughes Memorial Prize, open to Second-year Students, about £5 in books or instruments—Anatomy; Huxley Memorial Prize, 3 guineas in books or cash, open to Second-year Students—Physiology; Carter Gold Medal and Prize for Botany, open to Students of not more than three years' attendance, gold medal and books of the joint value of £15;

Jelf Medal awarded to Third-year Students; Second-year Scholarship, £20, Elementary Anatomy, Physiology, Histology, and Organic Chemistry; Daniell Scholarship, tenable for two years, £20, Chemistry; Rabbeth Scholarship, open to First-year Students, £20, Class Examinations in the Preliminary Scientific Course; and the Sambrooke King's College Scholarship in Science, value £25.

The Secretary to the Medical School is Dr. E. B. Hulbert (Librarian) to whom inquiries may be addressed.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN, 8, Hunter-street, Brunswick-square, W.C.—The fee for the medical course for the degrees of the University of London and for the diplomas of the Royal Colleges of England and for other qualifications is £169 in one sum, or £179 in five instalments. These sums include library and laboratory fees.

The Royal Free Hospital contains 184 beds, of which 78 are reserved for surgical, 64 for medical, 13 for gynæcological, six for ophthalmic, 11 for maternity, and four for isolation cases. Students can also attend the in-patient and out-patient practice of the Elizabeth Garrett Anderson Hospital.

An agreement has also been made under which students of the school attend full clinical courses at St. Mary's Hospital, Paddington (305 beds).

Special courses are arranged for the Primary Fellowship Examination of the College of Surgeons; also for dental students in conjunction with the London Dental Hospital, Leicester-square, and the National Dental Hospital.

Students after qualification can hold the posts of house physician, house surgeon, obstetric assistants, clinical assistants, anæsthetists and assistant anæsthetist, medical and surgical registrars, pathologists, medical electrician, and museum curator; and at the Medical School the posts of demonstrators in the departments of Anatomy, Physiology, Chemistry, and Physics. They can also hold posts at the Elizabeth Garrett Anderson Hospital, South London Hospital for Women and Children, and at four other hospitals in London officered by medical women. Many other resident posts in London and elsewhere are also open to them.

The School buildings have been entirely rebuilt in recent years, and there are spacious, well-equipped laboratories, which afford every facility for efficiency of teaching and practical work in all departments. An extension of the School was opened in 1916. The extension will enable 90–100 new students to be received at the School each year.

There are residential chambers at 8, Hunter-street, 25, Gordon-square, and 36, Tavistock-square, and the Warden can be consulted on the subject of other residences for students. The Students' Union arranges the social, athletic, and other clubs and societies at the School.

Scholarships and Prizes.—(*a*) Isabel Thorne Scholarship, £30. (*b*) St Dunstan's Medical Exhibition, £60 a year, tenable for three or five years. (*c*) Mrs. George M. Smith Scholarship, £50 a year, tenable for three or five years and next to be awarded in 1919. (*d*) Bostock Scholarship, tenable for two or four years, and next to be awarded in June, 1919, £60. (*e*) Mabel Sharman-Crawford Scholarship, tenable for four years, £20 a year. (*f*) Sir Owen Roberts Scholarship, £75 a year for four years. (*g*) Mabel Webb Research Scholarship, tenable for one year and renewable, £30, Physiology, Chemistry, or Pathology. (*h*) Fanny Butler Scholarship, tenable for four years; next award in July, 1918, £14 10*s*. (*i*) John Byron Bursary, tenable from two to four years, for students already in the School requiring assistance for the prosecution of their medical studies, application to the Secretary by March 31st; next award in March, 1919, £20. (*k*) Ellen Walker Bursary tenable for two years, awarded to a student beginning fourth year of medical study, £25 a year. (*l*) Helen Prideaux Scholarship, awarded every second year to a student who has become qualified during the two years immediately preceding the award, and to be spent in assisting the holder to further study, £40. (*m*) Agnes Guthrie Bursary, value £60, is offered annually to students who desire to pursue a full course of study for the Licentiateship in Dental Surgery. (*n*) Dr. Edith Pechey Phipson Post-graduate Scholarship of the value of £40, awarded annually in June. It is open to all medical women, preferably coming from India, or going to work in India, for assistance in Post-graduate study. (*o*) Sarah Holborn Scholarship, value £20 a year for three or five years, awarded every alternate year; next award in 1919. Two Richardson-Kuhlmann Prizes are given each year, value £12, for proficiency in Clinical Obstetrics, value £8, for proficiency in senior subjects respectively. Two Evans Prizes of £2 2*s*. and £1 1*s*. are given each year on the results of the class examination in Midwifery. The Evans Prize for Operative Midwifery, value £5 5*s*., is awarded yearly. The Edith Pechey Phipson Prize in Pharmacology, value £3 3*s*., is awarded annually. There is also a small loan fund from which assistance can occasionally be given to students and to graduates who specially require pecuniary help. Prizes and Certificates of Honour are awarded in each class at the end of the session.

The Dean of the Medical School is Miss Aldrich-Blake, M.D.; the Honorary Secretary, Dr. May Thorne; and the Warden and Secretary, Miss L. M. Brooks, to whom inquiries may be addressed.

UNIVERSITY OF DURHAM.

Two Diplomas, one Licence, and six degrees are conferred—viz., the Diploma in Public Health, Diploma in Psychiatry, the Licence in Dental Surgery, and the degrees of Bachelor of Medicine, Bachelor of Surgery, Master of Surgery, Doctor of Medicine, Bachelor of Hygiene, and Doctor of Hygiene.

For the degree of *Bachelor of Medicine* there are four professional examinations. The subjects of the First Examination are—Elementary Anatomy, Elementary Biology, Chemistry, and Physics. The subjects of the Second Examination are—Anatomy and Physiology. The subjects for the Third Examination are—Materia Medica and Pharmacy, Pathology, Medical Jurisprudence, Public Health, and Pathology and Elementary Bacteriology. The subjects of the Fourth Examination are—Medicine, Clinical Medicine and Psychological Medicine, Surgery and Clinical Surgery, Midwifery and Gynæcology, Therapeutics, and Diseases of the Skin, of the Throat, Nose, and Ear, and of Children.

It is required that at least one of the five years of professional education shall be spent in attendance at the University College of Medicine, Newcastle-upon-Tyne. Candidates who have passed the First and Second Examinations of the University will be exempt from First and Second Examinations of the Conjoint Board.

For the degree of *Bachelor of Surgery* every candidate must have passed the examination for the degree of Bachelor of Medicine of the University of Durham and must have attended one course of lectures on Operative Surgery and one course on Applied Anatomy. Candidates will be required to perform operations on the dead body and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degrees of *Doctor of Medicine* and *Master of Surgery* a candidate must not be less than 24 years of age and must satisfy the University as to knowledge of Greek or German. If he has not already satisfied the Matriculation Examiners in either Greek or German he must pass in one of these subjects at one of the ordinary matriculation examinations of the Newcastle division of the University. He must also have obtained the degree of Bachelor of Surgery of the University of Durham and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor of Surgery, in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice. The candidate for the M.D. degree must present an essay. The subjects of examination for the M.S. are:—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

Doctor of Medicine (without residence).—The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates shall not be under 40 years of age and shall have been in active practice for 15 years as registered medical practitioners. They shall produce certificates of moral character from three registered members of the medical profession. The fee will be 50 guineas, of which 20 guineas will be retained if the candidate fails to satisfy the examiners.

Candidates for any of the above degrees, diplomas or licence, must give at least 28 days' notice to Professor Howden, Secretary, College of Medicine, Newcastle-upon-

Tyne. In the case of the M.D. (essay) examination candidates must send in their essays six weeks before the date of the examination.

Scholarships and Prizes.—In connexion with this University the following Scholarships and prizes are awarded:—(*a*), (*b*), (*c*), and (*d*). Four Scholarships of £25 a year each, tenable for four years; the examination will be the September Matriculation Examination. Candidates must take English, Latin, Arithmetic, Euclid, Algebra, Geography, English History, with Greek or German, or both. (See College Calendar for special books.) Open to candidates desirous of being admitted as Medical Students. The successful candidates must take out their entire curriculum at the University of Durham College of Medicine, Newcastle-upon-Tyne. (*e*) Pears Scholarship of £50 a year (when vacant), tenable for three years; Matriculation Examination.—At the College of Medicine are: (*f*) Dickinson Scholarship, interest on £400 and gold medal; examination in Medicine, Surgery, Midwifery, and Pathology. Open to full students of the College of Medicine who have passed the third M.B. Examination. (*g*) Tulloch Scholarship, interest on £400; examination in Elementary Anatomy, Biology, Chemistry, and Physics. (*h*) Charlton Memorial Scholarship, interest on £700; examination in Medicine. Open to full students of the College entered for the class on the Principles and Practice of Medicine. (*i*) Gibb Scholarship, interest on £500; awarded annually as a Scholarship in Pathology to full student who passes the best examination in that subject. No student is eligible after completion of his curriculum. (*j*) Luke Armstrong Memorial Scholarship, interest on £680: Original Essay on some subject in Comparative Pathology. (If no essay of sufficient merit be presented the scholarship may be awarded to the candidate who, in passing the first part of the Examination for the B.Hy. Degree, obtains the highest number of marks in Comparative Pathology during the year.) Open to all Graduates in Medicine or Hygiene and candidates for these degrees who have spent six months at the University and whose age does not exceed 30 years. (*k*) Stephen Scott Scholarship, interest on £1000; Original Essay on any Surgical subject. Open to any graduate in Medicine or Surgery of the University or any student of the College of Medicine. Student's age must not exceed 30 years. (*l*) Heath Scholarship, interest on £4000. For 1916: Original Essay on Genito-urinary Tuberculosis: Its Etiology, Pathology, Methods of Spread, Prognosis, and Treatment. All Graduates in Medicine or Surgery of the University are eligible. (*m*) Gibson Prize, interest on £250 stock; examination in subject of Midwifery and Diseases of Women and Children. Open to students who have attended one course of lectures on Midwifery and Gynæcology. (*n*) Outterson-Wood Prize, interest on £250, in Psychological Medicine. (*o*) Turnbull Prize and Medal; examination in Surface Anatomy. Open to students at end of their second winter session.—At the Royal Infirmary is (*p*) Goyder Memorial Scholarship, interest on £325; awarded annually to student who most distinguishes himself in Clinical Medicine and Clinical Surgery at the Royal Infirmary. For further information apply to Professor R. Howden, Secretary of the College.

Hygiene.—The regulations with regard to the degrees in Sanitary Science will be found under the section on Public Health.

THE COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—Clinical instruction is given at the Royal Victoria Infirmary, containing 585 beds. In it adequate accommodation is provided for the study of the various special subjects, in addition to the ordinary clinical work.

NEWCASTLE-UPON-TYNE ROYAL VICTORIA INFIRMARY.—The Infirmary was founded in 1751, but has been entirely rebuilt, the new hospital being opened by His late Majesty King Edward VII. in 1906. The number of beds is 585. The number of in-patients annually is 9200 and of out-patients 69,000. The medical students of the University of Durham attend the practice of this hospital. Clinical Lectures are delivered by the Physicians and Surgeons weekly and ward demonstrations are given daily. Tutorial classes are held by the Assistant Physicians, Assistant Surgeons, and Surgical Registrars weekly, and demonstrations are given in the several out-patient departments daily. Pathological demonstrations are given by the Pathologist daily or as opportunity occurs, and in the new buildings nothing has been spared in perfecting scientific equipment. In addition to medical and surgical in-patient and out-patient departments the following special departments are fully equipped for teaching students: Ophthalmic, Throat, Nose, and Ear, Skin, Gynæcological, and Electrical. The hospital building contains the following laboratories: 1. Special Pathological Laboratory, attached to the post-mortem rooms. 2. Bacteriological Laboratory, in which all clinical bacteriological investigations are carried out—opsonic indices estimated with a view to treatment by vaccines and serums, &c. 3. There is in addition a Clinical Laboratory attached to each ward and to the out-patient department. There are five operating theatres in use in the hospital. The surgical practice is especially good. The session opens on April 17th and Oct. 2nd of each year. Applications for detailed information should be made to the acting Dean, Dr. D. Wells Patterson, at the hospital.

There are other institutions in addition to the Royal Victoria Infirmary at which the student of medicine of the University of Durham can receive clinical instruction. Practical Midwifery can be studied at the Newcastle Lying-in Hospital. Instruction is given in Psychological Medicine at the Northumberland County Asylum, Morpeth. A special course of instruction is given in the City Hospital for Infectious Diseases by the City Officer of Health. Ophthalmology is further taught at the Northumberland, Durham, and Newcastle Infirmary for Diseases of the Eye. Out-patients, 11,892; in-patients, 410. Secretary: Mr. Richard Smith, 61, Westgate-road, Newcastle-on-Tyne.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants the degrees of M.B., Ch.B., M.D., Ch.M., and also a degree and a diploma in Public Health. The course for the Bachelors' degrees extends over five years from the date of commencement of professional study. As a rule the first four of these years must be spent in the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees and of recognising examinations passed at such other Universities as exempting from the examinations in Chemistry, Physics, and Elementary Biology. In the case of such students at least three years must be spent in attendance upon classes at the University. The fifth year may be spent at any other school or schools of medicine recognised by the University. The students of the Medical Faculty can be members of the University Club, the University Athletic Club, and the University Officers' Training Corps, while they possess a guild—the Guild of Undergraduates—which is designed to be a recognised medium of communication between the teachers and the taught. The University Medical Society and the Dental Students' Society also offer opportunities of coöperation for mutual benefit.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed the Matriculation Examination of the Joint Board or an examination accepted in lieu thereof. All communications respecting the Matriculation Examination, and examinations accepted in lieu thereof, must be sent to the Secretary to the Board, Joint Matriculation Board, 24, Dover-street, Manchester. First Examination.—Chemistry and Physics and Elementary Biology. Second Examination.—Anatomy and Physiology. Third Examination.—General Pathology and Bacteriology, Materia Medica, and Practical Pharmacy. Fourth Examination (at the end of the fourth year).—Forensic Medicine, Toxicology, Public Health, Therapeutics, and Special Pathology. Two years' hospital work must have been accomplished. Final Examination.—Medicine, Surgery, Midwifery, Diseases of Women, Mental Diseases, and Ophthalmology. Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital three months, maternity hospital one month, and lunatic asylum three months. Vaccination instruction must be taken out and courses of Ophthalmology, Medical and Surgical Anatomy, and Operative Surgery.

Degrees of Doctor of Medicine and Master of Surgery.—At the end of one year from the date of having passed the final M.B., Ch.B. examination the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both.

Candidates for either of these degrees have to present a thesis embodying observations in some subject embraced in one of the departments of the medical curriculum, and in addition pass a general examination in Principles and Practice of Medicine for the M.D., and general examination in Principles and Practice of Surgery, including operations on the cadaver for the M.Ch. It will be in the power of the Board of Examiners to exempt from the practical parts of the examination a candidate whose thesis is of exceptional merit from any part of these examinations.

Fees.—Matriculation, £2; First Examination, £2; Second Examination, £2; Third Examination, £2; Fourth Examination, £2; Final Examination, £8; M.D. or Ch.M., £10.

At the University of Birmingham the following Scholarships are awarded:—(*a*) Myers Travelling Studentship of £150, tenable for one year, awarded by vote of committee to M.B., Ch.B. Birm., B.Sc. candidates, tenable at some University or Hospital not in Great Britain or Ireland; (*b*) Ingleby Scholarship of £10, awarded to the candidate at Final Examination obtaining highest "first-class" marks in the subjects of Midwifery and Diseases of Women; (*c*) Sydenham Scholarship of £42, tenable for three years, award of Council to orphan sons of medical practitioners; (*d*) Sands Cox Scholarship of £42, tenable for three years, awarded to the candidate, not being more than 19 years of age, taking the highest marks at the July Matriculation; (*e*) Dental Scholarship of £37 10*s*., Open Competitive Examination in subjects learned during apprenticeship; (*f*), (*g*), (*h*), and (*i*) Four Queen's Scholarships of £10 10*s*. each. In the Second and Fourth Examinations the Scholarship is awarded respectively to the student taking the first place and obtaining "first-class" marks. In the Third Examination the Scholarship is awarded to the student obtaining the highest "first-class" marks in Pathology and Bacteriology, provided that such student passes at the same examination in the subjects of Materia Medica and Practical Pharmacy. In the Final Examination the Scholarship is awarded to the candidate taking the first place in the examination—that is, obtaining the greatest aggregate number of marks—provided that in each of the subjects of Medicine, Surgery, and Midwifery he gains not less than 60 per cent. of the total available marks; (*j*) George Henry Marshall Scholarship of £10, awarded annually, for the encouragement of Research Work in Ophthalmology; and (*k*) Russell Memorial Prize, a prize of books, value about £2, awarded annually to the student who, not being of more than six years' standing as a student of the School of Medicine of the University, shall pass the best examination in the subject of Nervous Diseases.

Clinical Instruction.—The medical students of the University receive their clinical instruction by attending the amalgamated practice of the General Hospital and the Queen's Hospital, details of which follow.

The clinical instruction of the Birmingham medical students is carried on under the direction of the University Clinical Board. The hospitals present an excellent field for clinical work, possessing more than 500 beds, treating annually over 8000 in-patients and 100,000 out-patients. The students spend part of their curriculum in each hospital, and thus have every opportunity of acquiring a varied, full, and practical knowledge of their professional work. The curriculum is adapted in the first place to meet the needs of the students of the University of Birmingham, but it is also well adapted to the requirements of students preparing for the examinations of all other universities and licensing bodies. At the General Hospital there are open to the students the following appointments: A resident medical officer, elected annually (£100); a resident surgical officer, elected annually and eligible for re-election for three years (£100); a resident pathologist, elected for six months (£50); three surgical casualty officers, elected annually and eligible for re-election (£50); three house physicians and four house surgeons hold office for six months, receiving board, residence, and salaries at the rate of £50 a year; two house surgeons to the gynæcological, ophthalmic, and aural departments are elected every six months, receiving board, residence, and a salary of £50 a year; two assistant house surgeons are elected every three months, receiving board, residence, and salaries at the rate of £40 a year; a resident medical officer at the Jaffray Hospital, who is elected annually but is eligible for re-election, and who receives £150 a year; and a resident medical assistant at this hospital, who is not necessarily qualified, is provided with board and residence, and holds office for three months. At the Queen's Hospital there are open to the student the following appointments: Three house physicians, three house surgeons, and one obstetric and ophthalmic house surgeon, who hold office for six months and have salaries at the rate of £80 a year. Thirty-eight other appointments of varying value are at the City Workhouse and Workhouse Infirmary, at the Birmingham General and Branch Dispensaries, at the Birmingham Lunatic Asylums, at the City Fever Hospitals, at the Children's Hospital, at the Birmingham and Midland Eye Hospital, at the Orthopædic and Spinal Hospital, at the Maternity Hospital, and at the Ear and Throat Hospital.

THE BIRMINGHAM GENERAL HOSPITAL.—400 beds are in daily use, 5560 in-patients per annum. Special wards for children, gynæcological, septic and infectious cases; special beds for eye, ear, and skin cases. About 50,000 out-patients per annum. Laboratories for bacteriology and morbid histology. Separate rooms adjoin the medical and surgical wards for clinical pathology. Five operating theatres (one for out-patients), all designed and fitted on the most modern lines. In addition to clinical teaching given in the wards and out-patient department by the honorary staff, medical and surgical tutorial classes are held for senior and junior students. Clinical instruction in all the special departments. The Jaffray Branch Hospital contains 54 beds.

THE QUEEN'S HOSPITAL.—Similar arrangements for clinical teaching are made here, and the material also is excellent. Ward and tutorial classes are regularly conducted by the staff, there are daily clinics in the out-patient department, while teaching duties are definitely assigned to the house physicians and house surgeons. There are also special departments for gynæcology and ophthalmology.

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church-street, Birmingham.—This hospital possesses 120 beds, and there is an average daily attendance of out-patients of over 250. This institution is recognised by Universities and the Royal College of Surgeons, England, and Royal College of Physicians, London, as an ophthalmic hospital at which clinical instruction in ophthalmology may be received. Students attending for a period of three months will be granted certificates which will qualify for the University and Conjoint Board examinations.

UNIVERSITY OF LIVERPOOL.

The degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), and Master of Hygiene (M.H.).

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for the degrees of Bachelor of Medicine and of Surgery must have attained the age of 21 years on the day of graduation. At least two of the five years of medical study must have been passed in the University, and one year at least must have been passed in the University subsequently to the date of passing the First Examination. The other three years may be passed at any college or medical school recognised for this purpose by the University. Candidates must pass three examinations entitled respectively: the First Examination, the Second Examination, and the Final Examination. The fee is £5 for each examination. The subjects of the First Examination are: (1) Chemistry, Inorganic, Organic, and Physical; (2) Biology (Zoology and Botany); and (3) Physics. The examination is divided into two parts—namely, (1) Chemistry and Physics, and (2) Biology; and candidates may present themselves in these parts separately. The subjects of the Second Examination are (*a*) Anatomy and Physiology (including Physiological Chemistry and Histology), and (*b*) Materia Medica, Pharmacy, and Pharmacology. Candidates may present themselves in (*a*) or (*b*) separately. The subjects for the Final Examination are: (1) General Pathology and Morbid Anatomy; (2) Therapeutics; (3) Forensic Medicine and Toxicology; (4) Public Health; (5) Obstetrics and Diseases of Women; (6) Surgery, Systematic, Clinical, Operative, and Practical, including Ophthalmology; and (7) Medicine, Systematic and Clinical, including Mental Diseases and Diseases of Children. The Final Examination is divided into three parts, the first consisting of subject (1),

the second of subjects (2), (3), and (4), the third of subjects (5), (6), and (7). Candidates may present themselves in these parts separately. Candidates for the third part must have completed the fifth year of medical study.

Degrees of Doctor of Medicine and Master of Surgery.—No candidate will be admitted to the degree of Doctor of Medicine or Master of Surgery unless he has previously received the Degrees of Bachelor of Medicine and Bachelor of Surgery, and at least one year has elapsed since he passed the examinations for those degrees. Candidates for the degree of Doctor of Medicine are required to present a dissertation embodying the results of personal observations or original research, either in some department of medicine or of some science directly relative to medicine: provided always that original work published in scientific journals or separately shall be admissible in lieu of, or in addition to, a dissertation specially written for the degree.

At this University the following Scholarships and Fellowships and Prizes are awarded:—(*a*) and (*b*) Robert Gee Entrance Scholarships, two annually, of £25 each, tenable for two years, Joint Matriculation Board Examination held in July, open to First M.B. Course Students; (*c*) Lyon Jones Scholarship, No. 1, of £21 per annum, tenable for two years, Competitive Examination among Junior Students in First M.B. Subjects, Perpetual Course at the University; (*d*) Lyon Jones Scholarship, No. 2, of £21, Competitive Examination among Senior Students in Anatomy, Physiology, Pharmacology, and Materia Medica; (*e*) Derby Exhibition of £15, Competitive Examination among Fourth- or Fifth-year Students in Clinical Subjects, and Clinical School Exhibition of £15 annually for Fourth- or Fifth-year students; (*f*) University Scholarship of £25 for one year, awarded on results of Second Examination for the degrees; (*g*) Holt Fellowships, Physiology and Pathology, of £100 each, for one year; (*h*) Gee Fellowship, Anatomy, of £100, for one year; (*i*) Alexander Fellowship, Bacteriology and Pathology, of £100, for one year; (*j*) Johnston Colonial Fellowship, Bio-Chemistry, of £100, for one year; (*k*) John W. Garrett International Fellowship, Bacteriology, of £100, for one year; (*l*) Thelwall Thomas Fellowship, Surgical Pathology, of £100, for one year; (*m*) Ethel Boyce Fellowship in Gynæcological Pathology, of £100, for one year; numerous prizes and medals; (*n*) Mary Birrell Davies Memorial Fund Scholarship, of the value of £60, tenable for four years, offered for competition in alternate years; open only to women students who will have attained the age of 19 on the first day of October next following the award; students who are or have been registered day students of the University are eligible for election; holder to proceed to a University degree in Medicine; candidates must apply in writing to the Registrar, forwarding evidence of their qualifications, on or before July 1st.

Medical School Buildings.—Medical research has also been endowed with several new laboratories in which students can pursue research work after graduation. All the laboratories and class-rooms are situated close together, communicating with one another, and are made up of four large blocks of buildings which form one side of the College quadrangle. There are the Johnston Laboratories for Experimental Medicine, Bio-Chemistry, and Tropical Medicine; the Medical School for Anatomy, Surgery, Toxicology, and Ophthalmology; and the Thompson-Yates Laboratories for Physiology and Pathology.

Clinical Instruction.—The Clinical School of the University now consists of four general hospitals—the Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, and the Stanley Hospital; and of five special hospitals—the Eye and Ear Infirmary, the Hospital for Women, the Infirmary for Children, St. Paul's Eye Hospital, and St. George's Hospital for Skin Diseases. These hospitals contain in all a total of about 1134 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom. All the hospitals are within easy access of the University. There are a large number of appointments to house physicianships and surgeonships both at the general and special hospitals which are open to qualified students of the school.

School of Veterinary Science.—There is a school of Veterinary Science in connexion with the University which provides full courses of instruction for the M.R.C.V.S. Degrees of B.V.Sc., M.V.Sc., and D.V.Sc., together with a diploma in Veterinary Hygiene, are also granted by the University.

Public Health Department.—This is located in a separate building known as Ashton Hall, in which full courses of instruction are given to students for the Diplomas and Degrees of the University and of other Examining Boards.

Prospectuses and further information may be had on application to the Dean of the Faculty of Medicine, University of Liverpool.

THE VICTORIA UNIVERSITY OF MANCHESTER.

Four degrees in Medicine and Surgery are conferred by the University—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). A Diploma in Psychological Medicine is awarded by examination to registered medical practitioners.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation and that they have pursued the courses of study required by the University Regulations during a period of not less than five years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in the University and one year at least having been passed in the University subsequently to the date of passing the first M.B. Examination. All candidates for the degrees of Bachelor of Medicine and Bachelor of Surgery are required to satisfy the examiners in the several subjects of the following examinations.

The First Examination.—(1) Inorganic Chemistry and Physics; (2) Biology; and (3) Elementary Organic Chemistry and Bio-Chemistry. Candidates must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into three parts: Part 1, Inorganic Chemistry and Physics; Part 2, Biology; Part 3, Elementary Organic Chemistry and Bio-Chemistry; and the candidates may pass in these parts separately under certain conditions.

The Second Examination.—(1) Anatomy; (2) Physiology, including Physiological Chemistry and Histology. Candidates may pass in (1) and (2) separately under certain conditions.

The Third Examination.—(1) Pathology; (2) Pharmacology and Therapeutics; (3) Hygiene. These subjects may be taken separately under certain conditions.

The Final Examination.—(1) Medicine, Systematic and Clinical (including Mental Diseases and Diseases of Children); (2) Surgery, Systematic, Clinical, and Practical; (3) Obstetrics and Gynæcology (including Clinical and Practical); (4) Forensic Medicine (including an Oral Examination). These subjects may be taken separately under certain conditions.

Candidates for the Final Examination must have completed the fifth year of medical study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates may elect either (1) to present an original dissertation; or (2) to undergo an examination. The dissertation must embody the results of personal observation or original research, either in some department of medicine or of some science directly relative to medicine. The examination, which will be partly written, partly practical, is in the Principles and Practice of Medicine, in Pathology, and in some other subject to be selected by the candidate.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. The

subjects of examination are as follows: (1) Surgical Anatomy; (2) Surgery; (3) Operative Surgery; (4) Clinical Surgery; (5) Ophthalmology; and (6) Pathology and Bacteriology.

Communications should be addressed to the Registrar, The University, Manchester.

Scholarships, Fellowships, and Prizes.—At this University there are 22 Foundation Scholarships, 12 Exhibitions, five being for subjects connected with medical study, a Surgical Prize, a University Fellowship (Leech Fellowship, £100), Research Fellowships in Public Health, and Honorary Research Fellowships. 13 Entrance Scholarships are tenable for Medical courses; one Scholarship is offered in Surgery, Biology, Physiology, and Diseases of Children respectively, and one General Medical and Surgical. Exhibitions are offered in Physiology and Anatomy, and one for French and German. "The Dumville" Surgical Prize is awarded on the results of the Final Examination in Surgery in the Summer Term, £15. The Leech Fellowship (£100) is for the encouragement of study and research, and is open to persons who have graduated M.B., Ch.B., in the University not more than 18 months previously. The Honorary Research Fellowships, tenable for two years, conferring the right of free use of the laboratories, are awarded generally in October on application, with evidence of capacity for independent investigation.

There are many entrance scholarships, the examinations for which are held in the month of May. Full particulars can be obtained from the Dean.

The Medical School.—This medical school, largely extended in 1895, is provided with dissecting-rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. A special laboratory is equipped for experimental work on the central nervous system. In the pathological laboratories ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. The Helen Swindells Laboratory is specially equipped for cancer research and investigation in general pathology. Ample facilities for investigation are provided in Anatomy, Physiology, and Materia Medica. In the public health department, which is lodged in a separate institute in York Place, near the Royal Infirmary, suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology.

Clinical Studies.—The clinical and practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary and St. Mary's Hospitals for Women and Children, a fever hospital, a lunatic asylum, and a convalescent home, and other special hospitals. Medical and Surgical Clinical Classes are conducted in the Infirmary, which together with the associated hospitals at Cheadle contains 1109 beds, exclusive of those reserved for military cases, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary.

Clinical Instruction.—THE MANCHESTER ROYAL INFIRMARY.—The Royal Infirmary is built on the pavilion system, near the University, and has accommodation for 882 (including 510 temporary military beds). The remaining beds are allocated to civilians. The medical side consists of five units, each unit having a testing room for the scientific investigation of morbid products and a class-room. The surgical beds are also arranged in five units, each unit having its own operation theatre, with anæsthetising, recovery, sterilising, testing, and apparatus rooms, and its own class-room attached. Of these units all are occupied. The fine educational block provides very handsomely for the wants and comforts of the students, there being separate suites of rooms for the men and the women, and also a large common reading room, a lecture theatre, and a museum. The present annual average number of in-patients is 12,000, of out- and home-patients 32,000, and the list of casualties in the accident room has averaged 22,000 per annum. About 8000 operations are performed annually in the operation theatres. Associated with the infirmary are: (1) the Convalescent Hospital at Cheadle, containing 136 beds; (2) the Royal Lunatic Hospital at Cheadle, accommodating with its branches 430 patients; and (3) the Central Branch in the city for casualty and out-patient work, and 62 temporary military beds. The Associated Hospitals thus contain 1448 beds and are under the same management. Women students are admitted to the practice of the Infirmary on the same terms as men.

Fees.—Medical Practice: Three months, 5 guineas; six months, 8 guineas; 12 months, 12 guineas; full period required by the Examining Boards, 42 guineas.

Two Entrance Scholarships in Medicine of the value of £100 each are offered annually by the Council of the Manchester University and the Medical Board of the Manchester Royal Infirmary for proficiency in Arts and Science subjects respectively. Other scholarships and prizes are in the College Syllabus. Numerous annual appointments and junior appointments may be held by those who have attended the practice of the Infirmary.

The secretary to the Infirmary is Mr. F. G. Hazell.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, Gartside-street, Manchester, and St. Anne's-on-the-Sea.—The hospital contains 188 beds and 24 in the Convalescent Home, St. Anne's-on-the-Sea. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. Out-patients are seen daily at 9 A.M. at the new Out-patient Department, Gartside-street, Manchester. Secretary: Mr. W. M. Humphry.

THE MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road, Manchester.—The hospital contains 70 beds. Out-patients are seen daily from 8.30 to 10 A.M.

UNIVERSITY OF LEEDS.

Four degrees in Medicine and Surgery are conferred—viz.: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), also Degrees and Diplomas in Dental Surgery and Diplomas in Public Health and in Psychological Medicine.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for these degrees are required to present certificates showing that they will have attained the age of 21 years on the day of graduation, and have attended courses approved by the University extending over not less than five years, two of such years at least having been passed in the University subsequently to the date of passing the First Examination. Candidates must also satisfy the examiners in the several subjects of the following examinations entitled respectively: the Matriculation Examination, or such other examination as may have been recognised by the Joint Matriculation Board in its stead; the First Examination; the Second Examination; and the Final Examination.

The First Examination.—The First Examination consists of: Part I., Physics and Chemistry; Part II., Biology. Candidates will be allowed to pass the two parts separately.

The Second Examination.—The Second Examination consists of: Part I., Anatomy and Physiology; Part II., Materia Medica and Pharmacy. Candidates will be allowed to pass the two parts separately.

The Final Examination.—The Final Examination consists of: Part I., Pathology and Bacteriology. Part II., Forensic Medicine and Public Health. Part III., Medicine: Systematic and Clinical, including Mental Diseases and Diseases of Children; Surgery: Systematic, Clinical, and Practical; Obstetrics, and Gynæcology: Systematic, Clinical, and Practical; Pharmacology and Therapeutics. Candidates will be allowed to pass Parts II. and III. separately or together, and they may present themselves for examination in Part I. at the end of the tenth term.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine or Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine are required to present a dissertation and, if the dissertation be accepted, to pass an examination.

The first term commences on Sept. 30th. Prospectus, &c., can be obtained from the Dean of the Medical School.

Clinical Instruction.—THE LEEDS GENERAL INFIRMARY, in connexion with this medical faculty, has accommodation for 620 in-patients, including 88 beds at branch

hospitals in the country. During the last year 11,463 in-patients and 33,671 out-patients were treated. Clinical teaching takes place daily in the wards, and Clinical lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, Electro-therapeutic, and Radiographic Departments, in each of which special instruction is imparted to students. A Gynæcological and Extern Obstetric Department, together with Laryngeal and Skin Clinics, are in operation. Several valuable prizes are given at the end of each session. Numerous appointments at the Infirmary are annually open to students after qualification.

UNIVERSITY OF SHEFFIELD.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The courses and degrees in the Faculty of Medicine are open to men and women alike.

Candidates for a medical degree shall have matriculated in the University or have passed such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board.

A candidate for the degrees of M.B., Ch.B., shall produce certificates that he will have attained the age of 21 years on the day of graduation; that he has pursued the courses of study required by the University regulations during a period of not less than five years subsequently to the date of his matriculation, three of such years at least having been passed in the University, one at least being subsequent to the passing of the First Examination.

Degrees of Bachelor of Medicine and Bachelor of Surgery.

The First Examination.—The subjects of the examination are Chemistry, Physics, and Biology. The Intermediate B.Sc. Examination in these subjects will, on payment of the required additional fee, be accepted instead of this examination. Candidates must, after matriculation and registration as medical students, have attended courses of instruction (lectures and laboratory work) in chemistry, physics, and biology for one year each.

The Second Examination.—The subjects of the examination are Anatomy and Physiology.

The Third Examination.—The subjects of the examination are Pathology and Pharmacology. A candidate entering for the first, second, or third examination, who shall pass creditably in one subject of either examination and obtain a certain minimum of marks in the other, may enter for such other subject separately in a subsequent examination. Candidates must have completed the fourth year of professional study.

The Final Examination.—The subjects of the examination are Medicine (including Forensic Medicine, Public Health, Mental Diseases, and Diseases of Children); Surgery; and Obstetrics (including Gynæcology). Candidates must satisfy the examiners in all subjects at the same examination. Candidates must have completed the fifth year of professional study.

Degree of Doctor of Medicine.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the professor of medicine, and must pass an examination in the Principles and Practice of Medicine.

Degree of Master of Surgery.—Candidates for the degree of Ch.M. must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, and must, since taking the degrees of M.B., Ch.B., have held for not less than six months a surgical appointment in a public hospital or other public institution, affording full opportunity for the study of Practical Surgery.

The subjects of examination are Systematic, Clinical, and Operative Surgery, Surgical Anatomy, Surgical Pathology, and Bacteriology.

Scholarships, &c.—At this University, in addition to four Edgar Allen scholarships of £100 a year for three years, holders of which can take the courses in the Faculty of Medicine, there are 8 scholarships and a Town Trust Fellowship. Full particulars as to curriculum, scholarships, &c., may be had on application to the Registrar or to the Dean of the Medical Faculty.

The Medical School.—The new buildings of the University opened in 1905 are situated at the west end of the city, adjoining Weston Park, and the Medical Department occupies the entire north wing of the University quadrangle. The various athletic and other students' societies are under the management of a Students' Representative Council, elected annually. There are large and comfortable common rooms both for men and women students. A refectory is open daily at the University where students may obtain refreshments, lunch, dinner, &c., at extremely moderate prices. The University journal, *Floreamus*, edited by a committee of staff and students, is published each term. The University Hostel, "Oakholme," Clarkehouse-road, is recognised by the Senate as a residence for women students, full particulars of which may be obtained of the tutor for women students.

Clinical Instruction.—The University is within easy reach of the various hospitals with which it is connected for clinical purposes. These are as follows: The Royal Infirmary (Secretary, Mr. J. W. Barnes), containing 320 beds, with an annual average number of over 3800 in-patients, over 11,500 out-patients, and over 23,000 casualties; the Royal Hospital (Hon. Sec., *pro tem.*, to the medical and surgical staff, Mr. J. B. Ferguson Wilson), with 191 beds, and an annual number of 3000 in-patients, over 20,000 out-patients, and nearly 20,000 casualties; and the Jessop Hospital for Diseases of Women, with 80 beds, about 750 in-patients, and over 3000 out-patients; also a Maternity department, with about 450 in-patients per annum and about 700 out-patient cases attended. Special courses on Fevers are held at the City Fever Hospitals (570 beds) and on Mental Diseases at the South Yorkshire Asylum (1610 beds). For purposes of clinical practice the practices of the Royal Infirmary and Royal Hospital are amalgamated, giving a total of 511 beds for the treatment of medical, surgical, and special cases. There are special departments for the treatment of Diseases of the Eye at each institution, with wards assigned to them. In addition to these the Royal Infirmary has special departments for the treatment of Diseases of the Skin and Ear, with beds assigned to them, whilst at the Royal Hospital there are special out-patient departments for Diseases of the Throat, Ear, Skin, Orthopædics, and Mental Diseases. During the last year over 6000 patients passed through the wards of the two institutions, while those attending as out-patients numbered over 45,000. The department of Pathology and Bacteriology in the University is fitted with every requirement for the most advanced work in these subjects.

Fees.—The Composition Fee is £30 a year for each of the five years and entitles the student to attendance on *all* the Lectures, Laboratory Classes, and Hospital practice required for a Medical and Surgical Degree in the University or for the ordinary qualifying examinations of the various Examining Boards. The composition fees do not cover the cost of apparatus, instruments, parts for dissection in anatomy, &c., all of which must be provided by the student when and as required. The fees are payable in instalments extending over the five years of the curriculum.

UNIVERSITY OF BRISTOL.

In the Faculty of Medicine there are the following degrees:—Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There are also the following diplomas: Diploma in Public Health (D.P.H.), Diploma in Dental Surgery (L.D.S.), and Diploma in Veterinary State Medicine.

All candidates for degrees in Medicine, Surgery, and Dentistry are required to pass an examination called the Matriculation Examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women alike. The winter session commences on Tuesday, Oct. 1st, 1918.

Conjoined Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates shall be not less than 21 years of age and shall have pursued the courses prescribed by University Regulations during not less than five and a half years, of which three shall have been passed in the University, and two of these three subsequent to pass in the second examination. All candidates for the degrees of M.B., Ch.B., are required to satisfy the examiners in the several subjects of three examinations.

The First Examination.—The subjects of examination are: Chemistry (Inorganic), Physics, and Biology, the courses pursued being those for the time being approved for the intermediate part of the B.Sc. curriculum. This part of the curriculum shall extend over one year. (Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination and will be regarded as having completed one year of study.)

The Second Examination.—The subjects of examination are: Organic Chemistry and Elementary Anatomy (Part I.) and Advanced Anatomy and Physiology (Part II.). Parts I. and II. may be passed separately or together.

The Final Examination.—The subjects of examination are: Materia Medica and Pharmacy, Pharmacology and Therapeutics, General Pathology, Morbid Anatomy, and Bacteriology (Part I.); Special Pathology, Forensic Medicine, Toxicology, and Public Health, Obstetrics (including Diseases of Women), Surgery (Systematic, Clinical, Practical, and Operative), Medicine (Systematic, Clinical, and Practical, including Mental Diseases) (Part II.). Candidates may pass I. and II. together, or separately, and Forensic Medicine and Toxicology may, at the option of the candidate, be taken either with Part I. or Part II.

Degree of Doctor of Medicine.—Candidates shall be Bachelors of the University of not less than two years' standing as such and may elect either (1) to pass an examination in General Medicine, or (2) to pass an examination in State Medicine, or (3) to present a Dissertation. The candidate who elects to pass the examination in State Medicine must hold a diploma in Public Health of some University or College, and the candidate who elects to present a Dissertation may be examined in the subject thereof.

Degree of Master of Surgery.—Candidates shall be Bachelors of not less than two years as such, during which period they shall have attended the Surgical Practice of an institution approved for the purpose. They shall pass an examination in Surgical Anatomy, Pathology, and Bacteriology, and Operative, Clinical, and General Surgery, and present to the University a Dissertation on some subject of Surgery.

Clinical Instruction.—The allied hospitals (Bristol Royal Infirmary and Bristol General Hospital) have between them about 600 beds and extensive out-patient departments, special clinics for Diseases of Women and Children and those of the Eye, Throat, and Ear, in addition to large and well-equipped departments for Dental work and large outdoor Maternity Departments.

At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and laboratories for Morbid Anatomy. There are also laboratories for work in Clinical Pathology, Bacteriology, and Cytology, in which special instruction is given in these subjects. Departments are provided and well-equipped for X ray work, both for diagnosis and treatment, the various forms of Electrical treatment, including High Frequency Currents, Electric Baths, Finsen Light treatment, and Massage.

The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 140 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore about 750.

Further information as to scholarships, curricula, and fees can be obtained from the Dean of the Faculty of Medicine or the Registrar of the University.

UNIVERSITY OF WALES.

This University has the privilege of granting degrees in Medicine and Diplomas in Public Health. At the three constituent Colleges of Aberystwyth, Bangor, and Cardiff there are Professors of Chemistry, Botany, Zoology, and Physics, so that the students of the University can obtain proper instruction in the ancillary subjects. The foundation of a Medical Faculty has been laid at University College, Cardiff, where there is a recognised school of medicine.

University College, Cardiff: School of Medicine.—All classes are open to both men and women students who may spend three or four out of their five years of medical study at Cardiff. The courses of instruction given at Cardiff are recognised as qualifying for the examinations of the Universities, Royal Colleges, and other licensing bodies of Great Britain and Ireland, and they are specially adapted to meet the needs of those University students studying for Cambridge and London degrees. Students who are preparing for these examinations may compound for their courses by paying a fee of £63, while a composition fee of £41 10*s.* includes all the necessary courses for the first and second examinations for the Diploma of the Conjoint Board. In all cases the composition fees may be paid by instalments. Hospital instruction is given at the King Edward VII.'s Hospital, Cardiff. The attention of students about to matriculate is drawn to the numerous entrance scholarships offered for competition at University College, Cardiff, in April next, most of which may be held by medical students. Full particulars of the examination for these may be obtained by application to the Registrar. In the department of Public Health established in 1899 instruction is given qualifying for the D.P.H. examinations. Further information may be obtained from the Dean of the Faculty of Medicine.

Clinical Instruction.—KING EDWARD VII.'S HOSPITAL, CARDIFF.—Students can attend the practice of this Hospital, which contains 320 beds, 104 beds for military patients. Founded 1837. In-patients, 2717; out-patients, 13,746.——SWANSEA GENERAL AND EYE HOSPITAL AND SWANSEA HOSPITAL CONVALESCENT HOME.—Hospital, 188 beds; Convalescent Home, 25 beds. In-patients, 2177; out-patients, 7978.

ENGLISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Under this heading we give the regulations for the examinations enjoined by the Conjoint Examining Board of the Royal Colleges of Physicians of London and Surgeons of England and of the Society of Apothecaries upon students desiring their respective diplomas of qualification. We do not give any list of schools recognised by these bodies as eligible to prepare students for their examinations beyond mentioning that all the schools which we have already described (under the heading of the Universities to which they are attached) are recognised as suitable places of instruction by the corporations granting medical diplomas. The courses of study at the principal colonial medical schools are also recognised as qualifying for the examinations of these corporations.

Any candidate who desires to obtain both the Licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England is required to complete five years of professional study at recognised Medical Schools and Hospitals and to comply with the following regulations and to pass the examinations hereinafter set forth. Six months of the curriculum may be spent in an Institution recognised by the Board for instruction in Chemistry, Physics, Practical Chemistry, and Biology.

Professional Examinations.—There are three Examinations, called herein the First Examination, the Second Examination, and the Third or Final Examination, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and September or October unless otherwise appointed. Every candidate intending to present himself for examination is required to give notice in writing to Mr. F. G. Hallett, secretary of the Examining Board, Examination Hall, Queen-square, Bloomsbury, W.C., 14 clear days before the day on which the examination commences, transmitting at the same time the required certificates.

The subjects of the *First Examination* are—Chemistry, Physics, Elementary Biology, and Practical Pharmacy. A candidate may take this examination in three parts at different times (Chemistry and Physics must be taken together until the required standard is reached in both or in one of these subjects, but a candidate will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other). A candidate will be admitted to examination in Chemistry and Physics, in Practical Pharmacy, and Elementary Biology on producing evidence of having

passed the required Preliminary Examination and of having received instruction in these subjects at a recognised institution, but he may take Pharmacy at any time during the curriculum. A candidate rejected in one part or more of the First Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected. If referred in Chemistry, Physics, or Biology he must produce evidence of further instruction at a recognised institution. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in Medicine on any of the subjects of this examination conducted at a university in the United Kingdom, in India, or in a British colony will be exempt from examination in those subjects in which he has passed.

The fees for admission to the *First Examination* are as follows: For the whole examination, £10 10*s.*; for re-examination after rejection in Parts I. and II., £3 3*s.*; and for re-examination in each of the other parts, £2 2*s.*

The subjects of the *Second Examination* are Anatomy and Physiology. Candidates will be required to pass in both subjects at one and the same time. Candidates will be admissible to the Second Examination on production of the required certificates of professional study. The study of Anatomy and Physiology before passing in two of the first three parts of the First Professional Examination is not recognised.

A candidate referred on the *Second Examination* will be required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, in a recognised place of study, his Anatomical and Physiological studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the *Second Examination* are: £10 10*s.* for the whole examination and £6 6*s.* for re-examination after rejection.

The subjects of the *Third* or *Final Examination* are: Part I. Medicine, including Medical Anatomy, Pathology, Practical Pharmacy, Therapeutics, Forensic Medicine, and Public Health. Candidates who have passed in Practical Pharmacy at the First Examination will not be re-examined in that subject at the Third Examination. Part II. Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances. Part III. Midwifery and Diseases Peculiar to Women. Candidates may present themselves for Parts I., II., and III. of the examination separately or together at the expiration of not less than two years (24 months) from the date of passing the Second Examination on production of the certificates of study required for the respective parts, provided that the examination is not completed before the expiration of five years from the date of passing the Preliminary Examination.

The fees for admission to the *Third* or *Final Examination* are as follows: For the whole examination, £21. Part I. For re-examination in Medicine, including Medical Anatomy, Pathology, Therapeutics, Forensic Medicine, and Public Health, £5 5*s.*; for re-examination in Practical Pharmacy (if taken at this examination), £2 2*s.* Part II. For re-examination in Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances, £5 5*s.* Part III. For re-examination in Midwifery and Diseases Peculiar to Women, £3 3*s.*

A candidate referred on the *Third* or *Final Examination* will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection and will be required, before being admitted to re-examination, to produce a certificate, in regard to Medicine and Surgery, of having attended the Medical and Surgical Practice, or the Medical or Surgical Practice, as the case may be, during the period of his reference; and in regard to Midwifery and Diseases Peculiar to Women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

Students of recognised universities in England, Scotland, and Ireland, who have passed examinations for a degree in Medicine at their universities in the subjects of the First and Second Examinations of the Examining Board, may enter for the Final Examination at the expiration of two years from the date of passing in Anatomy and Physiology on production of the required certificates.

Members of certain recognised Indian, Colonial, and Foreign universities who have passed examinations for the Degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the First and Second Examinations of the Examining Board may present themselves for the Final Examination under special conditions which can be ascertained on application to the Secretary.

ROYAL COLLEGE OF PHYSICIANS OF LONDON: THE MEMBERSHIP AND FELLOWSHIP.

In addition to the diplomas granted by the English Conjoint Board, the Royal College of Physicians of London and the Royal College of Surgeons of England grant honour diplomas, which no longer give the right to practise professionally if held separately. The Royal College of Physicians of London has two such diplomas, the *Fellowship* which is a purely honorary distinction and the *Membership* which is obtained by examination.

Membership.—Every candidate for the Membership of the College must furnish proof of having attained the age of 25 years. Candidates must not be engaged in trade, dispense medicine, make any arrangement with a chemist or any other person for the supply of medicine, or practise medicine or surgery in partnership, by deed or otherwise. Any candidate being already registered or having passed a qualifying examination in accordance with the Medical Act of 1886, who has obtained the degree of Doctor or Bachelor of Medicine at a University in the United Kingdom, in India, or a British colony, or who has obtained a foreign qualification entitling him or her to practise medicine or surgery in the country where such qualification has been conferred, wherein the courses of study and the examinations to be undergone previously to graduation have been adjudged by the Censors' Board to be satisfactory, will (if the Censors think fit) be admitted to the Pass Examination. The nature and extent of this examination will, in the case of each candidate, be determined by the Censors' Board. All other candidates must produce proof of having passed the examinations required for the Licence of the College. The examination is directed partly to pathology and partly to the practice of medicine and may be modified in circumstances to be ascertained by application to the Registrar. For example, candidates under 40 years of age are examined in an ancient and a modern language, a test from which their seniors are exempt. The fee for admission as a Member of the College is 40 guineas, except when the candidate for Membership is a Licentiate of the College, in which case the fee already paid for the Licence shall be deducted from the 40 guineas. The fee for the examination is £6 6*s.*

Fellowship.—The *Fellows* are selected annually from the ranks of the *Members* by the Comitia of the College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: THE FELLOWSHIP.

The Royal College of Surgeons of England confers its diploma of Fellow upon a few distinguished persons in an honorary capacity. Two Members of long standing may also be elected to the Fellowship annually. But the bulk of the Fellows obtain the diploma as the result of examination.

Fellowship.—The examination for the Fellowship is divided into two parts—viz., the First Examination and the Second Examination. The subjects of the First Examination are Anatomy and Physiology, and the questions on these subjects may require an elementary acquaintance with Comparative Anatomy and Physiology. The examination is partly written and partly *vivâ voce*. The subjects of the Second Examination are Surgery, including Surgical Anatomy and Pathology. The examination is partly written and partly *vivâ voce* and includes the examination of patients and the performance of operations on the dead body. The examinations are held during the months of May and November of each year.

The fees for examination are:—First Examination, each admission, 5 guineas. Second Examination, each admission, 12 guineas. Of such examination fees 17 guineas will be reckoned as part of the fee payable upon admission to the Fellowship. The fee to be paid upon admission to the Fellowship is 30 guineas, except when the candidate is a Member of the College, in which case the fee is 20 guineas.

A Member of the College is admissible to the First Examination at any time after receiving his Diploma of Membership. A candidate who is not a member of the College is admissible to the first Professional Examination for the Fellowship on the production of evidence of having passed the First and Second Examinations of the Examining Board in England by the Royal College of Physicians of London and the Royal College of Surgeons of England (or, if a member of a University recognised by the College for the purpose, of having passed the Examinations in his University equivalent to the First and Second Examinations of the Board) and on the production of certificates of attendance upon certain courses of study described in the Regulations.

A Member of the College is admissible to the Second Examination at any time after having passed the First Examination, on producing satisfactory evidence of having been engaged not less than six years in the study (or study and practice) of the profession.

A candidate who is not a Member of the College must possess the registrable surgical and medical degrees of universities recognised by the Council and must have been engaged in the study (or study and practice) of the profession for not less than four years subsequent to the date of obtaining the recognised qualification, one year of which shall have been spent in attendance on the Surgical Practice of a recognised hospital. The diploma of Fellow is not conferred upon successful candidates until they have attained the age of 25 years.

The Regulations may be obtained on application to the Director of Examinations, Examination Hall, Queen-square, Bloomsbury, London, W.C. 1.

SOCIETY OF APOTHECARIES OF LONDON.

There are two examinations—Primary and Final. The Final examination is divided into Section I. and Section II. The Primary examination is held quarterly. Final examinations are held monthly. No examinations are held in the month of September.

The Primary examination consists of two parts. Part I. Elementary Biology; Chemistry, Chemical Physics, including the Elementary Mechanics of Solids and Fluids, Heat, Light, and Electricity; Practical Chemistry; and Materia Medica and Pharmacy. Part II. includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of twelve months' Practical Anatomy with Demonstrations, and these subjects cannot be taken separately except in the event of the candidate having previously passed in one. A schedule for the Primary examination, to be obtained of the Secretary, must be signed by the Dean of the Medical School or other authority. Section I. of the Final examination consists of three parts. Part I. includes the Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulation, Instruments, and Appliances. Part II. includes the Principles and Practice of Medicine, Pharmacology, Pathology, and Morbid Histology; Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases. Part III. includes Midwifery, Gynæcology, and Diseases of New-born Children and the Use of Obstetric Instruments and Appliances. Section I. of the Final examination cannot be passed before the expiration of 45 months from the date of commencement of medical study, during which time not less than three winter sessions and two summer sessions must have been passed at one or more of the medical schools connected with a general hospital recognised by the Society. Section II. of the Final examination consists of two Parts. Part I. Clinical Surgery; Part II. Clinical Medicine and Medical Anatomy. Section II. cannot be passed before the end of the fifth year.

The course of study for the *Primary examination* is as follows:—Elementary Biology, not less than three months; Chemistry and Chemical Physics, six months; Practical Chemistry, three months; Pharmacy and Dispensing, three months; Anatomy, six months; Practical Anatomy with Demonstrations, 12 months; Physiology, six months; Histology with Demonstrations, three months. The study of these subjects must be pursued at a Medical School recognised by the Society. Instruction in Pharmacy and Dispensing must be given by a registered medical practitioner or by a member of the Pharmaceutical Society by examination, or in a public hospital, infirmary, or dispensary.

The course of study for the *Final examination, Section I.*, includes attendance on the Surgical and Medical Practice (with Post-mortem Examinations) at a hospital connected with a medical school for a period of two winter and two summer sessions; lectures on the Principles and Practice of Surgery, six months; Practical Surgery, three months; Clinical Surgical Lectures, nine months; Dressership, six months; Performance of Surgical Operations on the Dead Body; lectures on Principles and Practice of Medicine, six months; Pathology, three months; Clinical Medical Lectures, nine months; Clinical Clerkship, six months; Forensic Medicine, Hygiene, and Insanity, three months; Midwifery and Gynæcology, three months; Clinical Instruction in the same, three months; a course of Practical Midwifery; attendance on 20 Midwifery cases. The course of medical study must extend over the above-mentioned period of 45 months, and the offices of dresser or clinical clerk must be held at a hospital or other institution recognised by the Society. Two years must elapse after a candidate has passed the examination in Anatomy and Physiology before he is eligible to sit for any part of the Final examination.

The course of study for the *Final examination, Section II.*, includes either attendance on the Practice of Medicine and Surgery at a hospital or other institution recognised by the Society for a further period of 12 months, or six months as above and six months as a pupil of a registered practitioner holding a public medical or surgical appointment, or attendance at two special hospitals for six months (three months at each hospital), and for six months at a general hospital, all such hospitals to be recognised by the Society. Evidence shall also be given of practical instruction in Infectious Diseases and in Mental Diseases (at a lunatic asylum or in the wards of an institution containing a special ward set apart for the treatment of mental diseases), and in any two of the following subjects: Ophthalmic Surgery, Laryngology with Rhinology and Otology, Dermatology, and Diseases of Children. No candidate is eligible for the Final examination who has not completed the curriculum prescribed by the Society, in evidence of which a schedule, to be obtained of the Secretary, must be produced, signed by the Dean of the Medical School or other authority. Prior to Section II. of the Final examination the candidate must produce certificates: (1) of being 21 years of age; (2) of moral character; (3) of the course of medical study; (4) of proficiency in vaccination signed by a teacher authorised by the Local Government Board; and (5) of instruction in the administration of anæsthetics. Candidates intending to present themselves for examination are required to give 14 days' notice. A form for this purpose will be sent on application.

Licentiates are eligible for the Membership of the Society of Apothecaries. Particulars may be obtained on application to the clerk.

The fee for the Licence is 20 guineas. Female candidates are admitted to examinations. The examination offices are open from 10 A.M. to 4 P.M.: on Saturdays from 10 A.M. to 1 P.M. All letters should be addressed to the Secretary, Court of Examiners, Society of Apothecaries of London, Blackfriars, E.C. 4.

METROPOLITAN ANCILLARY SCHOOLS AND HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

The institutions which follow provide to the medical student and medical graduate facilities for different forms of instruction and clinical observation. In each case further information can be obtained from the secretary of the hospital.

THE SEAMEN'S HOSPITAL SOCIETY possesses two hospitals—the *Dreadnought* Hospital at Greenwich, 250 beds, and the Branch Hospital in the Royal Victoria and Albert Docks, E., 50 beds; and the Angas Home 30 beds. It has also two Dispensaries—one in the East India Dock-road and the other at Gravesend—from which the patients are transferred to the hospitals. The London School of Clinical Medicine is attached to the *Dreadnought* Hospital. For the present the services of the School have been placed

at the disposal of the War Office in connexion with special Courses which are being given to Medical Officers belonging to the Army, who are going abroad. Secretary: Mr. P. J. Michelli, C.M.G.

WEST LONDON HOSPITAL, Hammersmith, W. — This hospital has 160 beds, all of which are constantly in use. 2440 in-patients and 30,322 out-patients, whose attendances numbered 155,870, were treated last year. Attached to the hospital is the West London Post-Graduate College. The practice of the hospital is reserved exclusively for qualified men, no junior students being admitted. Instruction is given in the medical and surgical out-patient rooms and demonstrations are given in the wards every morning and afternoon. Lectures and demonstrations are in abeyance during the war. Special Classes are held in Diseases of the Throat and Nose, Skin, and Eye, and in Gynæcology, Medical Electricity, Operative Surgery, Bacteriology, Anæsthetics, Intestinal Surgery, Medical and Surgical Diseases of Children, Blood and Urine, Clinical Microscopy, Tropical Medicine, Cystoscopy, Venereal Diseases, and Operative Ophthalmology. The accommodation for post-graduates consists of a large lecture room, together with reading, writing, and class rooms, &c. The hospital has a fully equipped pathological laboratory at which instruction is given in elementary bacteriology, a class being held every month. The fees for hospital practice, including lectures, are £6 6*s*. for three months or £15 15*s*. for one year. The certificate of the hospital is accepted by the Admiralty, War Office, Colonial Office, and India Office in cases of study leave. Further information can be obtained on application to the Dean, Mr. Donald Armour, or Vice-Dean, Mr. Bishop Harman, at the hospital. Secretary of the Hospital: Mr. A. Betteridge.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N. —This hospital is recognised by the Examining Board in England of the Royal Colleges of Physicians and Surgeons as a place of study during the fifth year of the medical curriculum. Besides the Honorary Staff there are six Anæsthetists, Pathologist, Resident Medical Officer, two resident House Physicians, and three resident House Surgeons. The hospital contains 350 beds (including emergency beds), which are fully occupied. There is also a ward for children under five years of age. The large rectangular and circular wards, each of which contains 35 beds, the observation wards, the two operation theatres, general and special out-patient and pathological departments, are specially designed with a view of offering the greatest facilities for clinical work. There is also a well-appointed electrical department. The Pathological Department has been extended and is under the control of a Director of Clinical Pathology. The Reckitt Convalescent Home at Clacton-on-Sea belongs to the hospital. It contains 60 beds. Medical practitioners are cordially invited to see the general and special practice of the hospital. Demonstrations are given daily in the wards and out-patient departments. Clinical assistants (qualified), clinical clerks, and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their terms of office. Further particulars from the Secretary of the Medical Committee at the Hospital.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.— This general hospital is in the midst of a densely populated neighbourhood of more than half a million inhabitants. It contains medical, surgical, gynæcological, and children's wards, having 125 beds. There are special departments for gynæcological cases, diseases of the eye, ear, throat, and nose, skin diseases, medical electricity, radiography, and dentistry. Operations are performed every afternoon of the week (except Saturday) at 2.30 P.M. Clinical instruction, ordinarily including laboratory classes, and lectures are given in the wards and out-patient departments, laboratories, and lecture hall in connexion with the North-East London Post-Graduate College attached. There are four Resident Medical Officers, and Clinical Assistants are appointed under certain conditions. Further particulars in regard to the hospital may be obtained from Mr. H. W. Carson, Secretary to the Medical Committee, 111, Harley-street, W.; or from Dr. A. J. Whiting, Dean of the North-East London Post-Graduate College, 19A, Cavendish-square, W. Secretary: Mr. F. W. Drewett.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. (Established 1873; Incorporated 1917).—The hospital contains 120 beds. The in-patients in 1917 were 1155, and the out-patients and casualties numbered 14,064 new cases. The medical and surgical practice of the hospital is open to students and practitioners. Operations: Mondays at 2 P.M., Tuesdays, Wednesdays, and Fridays at 9 A.M.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.—The Hampstead General Hospital (Haverstock Hill) and the North-West London Hospital (formerly at Kentish Town) have been amalgamated since 1907. The Hampstead General Hospital (137 beds—viz., 118 free, 6 isolation, &c., and 13 paying or contributory; out of these, 53 beds are reserved for soldiers) accommodates the in-patients from the districts hitherto served by both hospitals. The out-patients, with the exception of Hampstead casualty and emergency cases, attend exclusively at the Out-patients Department, Bayham-street, Camden Town. Further particulars from the secretary at the hospital (Haverstock Hill, N.W.).

ELIZABETH GARRETT ANDERSON HOSPITAL, 144, Euston-road, N.W.—A considerable number of the students work in the E.G.A. Hospital under the visiting staff, and in return for much valued clinical teaching they perform the duties assigned to students in the wards of a general hospital. Secretary: Miss Imogen H. Murphy.

THE SOUTH LONDON HOSPITAL FOR WOMEN, 103, South Side, Clapham Common, S.W.; Out-patient Department: 86–90, Newington Causeway, S.E.—This hospital, officered entirely by medical women, is a general hospital for women, girls, and small children of both sexes, and provides accommodation for 80 patients. All diseases are treated with the exception of acute infectious fevers and mental disease. There are Ophthalmic, X Ray, and Pathological Departments. The provision of additional facilities for post-graduate training for medical women is one of the special objects of the hospital. The number of in-patients treated during the year 1917 was 976. At the Out-patient Department in Newington Causeway 7095 new cases were treated during the past year, the total number of out-patient attendances amounting to 28,248. Clinical assistants (qualified women only) are from time to time appointed in the Out-patient Department. Secretary: Miss M. E. Ridler.

FRENCH HOSPITAL AND DISPENSARY, Shaftesbury-avenue, W.C.—This hospital, which was founded in 1867 to afford medical treatment for poor foreigners who speak the French language, has 87 beds, of which 48 are now occupied by British wounded soldiers. The French (Convalescent Home and Retreat for Aged French People at Brighton) contains 91 beds, of which 60 are now occupied by British wounded soldiers. Secretary: Mr. G. Pondepeyre.

ITALIAN HOSPITAL, Queen-square, W.C.—This institution was established in 1884 for the maintenance and medical treatment of Italian and Italian-speaking people, irrespective of their religious and political opinions, who may be suffering from sickness or bodily infirmity, but the sick poor of any nationality are also admitted for treatment. The institution also provides surgical and medical relief to Italians and others not being inmates of the hospital. It has 50 beds normally, now increased to 85, of which 60 are devoted to British wounded.

GERMAN HOSPITAL, Dalston, N.E.—This hospital was founded in 1845 with the object of supplying medical aid to poor people speaking the German language and for cases of emergency and of accident. It has 154 beds, including a sanatorium with 12 beds and a convalescent home at Hitchin with 40 beds.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Albany Memorial), Queen-square, Bloomsbury, W.C.—The hospital, with the Finchley branch, contains 210 beds and cots. The physicians attend every Monday, Tuesday, Thursday, and Friday at 2 P.M. In- and out-patient practice at that hour. Clinical Clerks are appointed under the in-patient and out-patient physicians. Lectures are given on Tuesdays and Fridays at 3.30. The hospital has been recognised by the Conjoint Board for England as a place where part of the fifth year may be devoted to clinical work. All communications concerning clinical appointments, lectures, hospital practice, and fees should be addressed to the Secretary at the hospital.

HOSPITAL FOR EPILEPSY AND PARALYSIS, &c., Maida Vale, W. (85 beds), and Golder's Green (100 beds for invalided soldiers).—Both in-patient and out-patient departments of this hospital are open free to students as well as to medical graduates. Secretary and General Superintendent: Mr. H. W. Burleigh.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, PARALYSIS, AND EPILEPSY, 73, Welbeck-street, W.—Graduates in medicine and senior students may attend demonstrations in the Out-patient Department. No fees are charged. The Savill Prize and Medal are at present in abeyance. Owing to the war, routine demonstrations by the staff have been discontinued for the present.

BETHLEM ROYAL HOSPITAL, St. George's Circus, S.E.—This hospital is open for the admission of two Resident House Physicians who have recently obtained their diplomas to practise Medicine and Surgery. They are permitted to reside in the hospital for a term generally not exceeding six months, commencing May 1st and Nov. 1st, and are provided with apartments, complete board, attendance, laundry, and a salary at the rate of £100 per annum. They are under the direction of the Physician Superintendent and are elected by the Committee from candidates whose testimonials appear to be most satisfactory. The students of certain specified London Medical Schools receive Clinical Instruction in the wards of the hospital and qualified practitioners and other students may attend for a period of three months on payment of a fee.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton (333 beds).—The hospital contains 333 beds. The Sanatorium at Frimley contains 100 beds and 50 beds for paying patients. Six House Physicians reside in the hospital for a term of six months; their duties include attendance in the out-patient department. Pupils are admitted to the practice of the hospital: terms, £1 1*s.* for one month; three months, £2 2*s.*; perpetual, £5 5*s.* Clinical Demonstrations are given throughout the year by members of the medical staff. Lectures have been suspended for the duration of the war. Clinical Assistants are appointed to the Assistant Physicians in the out-patient department and Clinical Clerks to the Physicians in the wards. The hospital has been recognised by the Conjoint Board for England as a place where six months of the fifth year may be spent in clinical work. The medical practice of the hospital is also recognised by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. Dean of the Medical School: Dr. Cecil Wall.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—During the past year 783 in-patients have been treated in the wards. The out-patients treated during 1917 numbered 9730. Address "Secretary of the Medical Committee."

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City road, E.C. (80 beds.)—This hospital provides accommodation for 80 in-patients. Expenditure for 1917 £14,198. income £28,442. The attendance of out-patients averages 25,000 annually. Secretary: Mr. A. T. Mays.

THE MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, NORTHWOOD, CENTRAL OUT-PATIENT DEPARTMENT, Fitzroy-square, W.—The hospital contains 110 beds. Number of in-patients, 461; out-patients, 3279. Resident Medical Staff. Clinical Demonstrations are given by the Visiting Medical Staff at the hospital at Northwood. Clinical assistants are appointed to physicians in the wards and in the out-patient department. Secretary: Mr. W. J. Morton. Offices: 7, Fitzroy-square, W.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL AND MIDWIFERY TRAINING SCHOOL, Marylebone-road, N.W.—This hospital receives about 2000 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases—nearly one-half of the total admissions. Clinical instruction is given on the more important cases which present themselves. Certificates of attendance at this hospital are recognised by all the Universities, Colleges, and licensing bodies. Pupil midwives and monthly nurses are received and specially trained. A Residential College provides accommodation for five men at a time, students and qualified practitioners, and is opposite the hospital, with which it is in telephonic communication. Arrangements have been made for Medical Students to receive the preliminary instruction in Practical Midwifery recommended by the General Medical Council. Women students are received, and the Resident Medical Officers are women at present. For further particulars application should be made to Mr. Arthur Watts, Secretary, at the hospital.

THE HOSPITAL FOR WOMEN, Soho-square, W.—In connexion with the out-patient department there has been for some years a well-organised Clinical Department. The appointments are open to qualified medical men and women. Every facility is afforded them by the gynæcologists in the out-patient department of obtaining experience in diagnosis and treatment and the practical use of instruments. Fee for one month £2 2*s.*; for each subsequent month the same. The hospital contains 67 beds. In the out-patient department there were over 4000 new cases during the past year, the total number of out-patient attendances being 14,500. This large number affords exceptional opportunities for examining and studying most of the varieties of the diseases of women. Applications should be made to the Secretary, Mr. Alfred Hayward.

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.—Qualified practitioners are admitted as clinical assistants to both the in- and out-patient departments. Demonstrations are given daily in both departments. The fees, payable in advance, are £3 3*s.* for three months. Full particulars may be obtained on application to the Secretary at the hospital. There are 70 beds. Secretary: Mr. G. H. Hawkins.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.—The hospital maintains 126 cots, and on an average 245 out-patients are seen daily. Clinical instruction is given by the physicians and surgeons to the hospital, which is recognised by the Conjoint Board for England as a school of medical teaching for students in the fifth year of the curriculum. All particulars may be obtained on application to the Secretary. Two clinical clerkships for qualified or unqualified students are open every three months subject to reappointment if desired. Clinical assistants (qualified men only) are from time to time appointed in the out-patient department. Any additional information may be obtained on applying to Mr. W. M. Wilcox, the Secretary, at the hospital.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C. 1, contains 210 beds, besides 30 beds at the Branch Hospital, Highgate. The hospital having been recognised by the Conjoint Board for England as a place where, under the new curriculum, six months of the fifth year may be spent in clinical work, the practice is arranged to meet this need and is open to students of both sexes who have completed four years of medical study and also to qualified medical men and women. The medical staff are recognised by the University of London as teachers in Diseases of Children. Arrangements have been made with University College Hospital for the routine admission of their students of both sexes to clerkships and dresserships in the wards. Appointments are made every three months to six medical clerkships, which are open to students of the hospital. Clinical instruction is given daily by members of the visiting staff. Fees for hospital practice, one month, £2 2*s.*; three months, 5 guineas; perpetual ticket, 10 guineas. Clinical Clerks, 1 guinea for three months. Ophthalmological Clerkships.—Clinical Clerks are appointed once a month. Fees £1 1*s.* for one month's attendance. Pathological Clerkships.—Facilities are afforded for obtaining theoretical and practical instruction in Clinical Pathology and Bacteriology in the Pathological Laboratories. Clerks attend for about four hours daily. Fees: For one month, £3 3*s.*; for two months, £5 5*s.*; for three months, £6 6*s.* A reduction is made in the case of those already holding tickets for general attendance at the hospital. Secretary: Mr. Stewart Darmady.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, S.E.—This hospital contains 76 cots and a very extensive Out-patient Department. About ten clinical assistants (either sex), to work with the Honorary Medical Staff for Out-patients, are appointed quarterly for a period of three months; there is no salary attached to these posts; but, on the other hand, no fees are charged. Secretary: H. C. Staniland Smith.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—The hospital contains 104 beds and has a large out-patient department (over 1200 weekly); the home at Broadstairs has 50 beds, and the home at Biggin Hill, Kent, has 14 beds. Out-patients are seen as under:—Diseases of the Eye: Tuesday, 2 P.M. Diseases of the Skin: Wednesday, 1.30 P.M. Whooping-cough Cases: Friday, 2.30 P.M. Dental Cases: Thursday, 1.30 P.M. Medical and Surgical Cases: Mornings at 9.30. Accidents and urgent cases are admitted at any time. Secretary, Mr. H. G. Evered.

THE QUEEN'S HOSPITAL FOR CHILDREN (*late North-Eastern Hospital for Children*), Hackney-road, Bethnal Green, E. (Telephone 305 Dalston.) For the sick children of the poor under 14 years of age. Established 1867. 134 beds in London and 30 at the seaside branch, "Little Folks" Home, Bexhill. —During the past year 2029 in-patients and 42,225 out-patients (attendance 98,346) were relieved, 736 of the in-patients being infants under two years of age. The surgeons attend on Tuesdays and Wednesdays at 1.45 P.M. and Fridays and Saturdays at 9.30 A.M.; the physicians daily at 1.45 P.M., except Saturday, 9.30 A.M., and Wednesday and Friday, 9.30 A.M., as well as 1.45 P.M. A course of clinical demonstrations and lectures, open free to medical practitioners and students of medicine of both sexes, is usually given during the winter session. Secretary, Mr. T. Glenton-Kerr.

THE BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—Clinical Assistants (men or women) are from time to time appointed to the members of the Visiting Staff attending in the Out-patient Department at this hospital, and facilities are given for attendance in the wards.

ALEXANDRA HOSPITAL FOR CHILDREN WITH HIP DISEASE, Queen-square, W.C.—At this hospital students who have obtained a recommendation from their teachers can attend to see the practice. The out- and in-patients' clinic is held on Mondays at 2.30 P.M., subject to alteration during the war.

ROYAL LONDON OPHTHALMIC HOSPITAL (Moorfields, 1804–1899), City-road, E.C. 138 beds.—This hospital, known as Moorfields Eye Hospital, was moved in 1899 to larger buildings in City-road. In 1917 there were 2248 in-patients, the out-patients were 45,770, of whom 40,055 were new out-patients, and the attendances were 109,364. Operations are performed daily from 10 A.M. to 1 P.M., and four surgeons attend on each day. Students are admitted to the practice of the hospital. Fee for six months, £3 3*s.*; perpetual, £5 5*s.* A special Clinical demonstration is given by a member of the staff in the out-patient department every morning. Courses of instruction on the following subjects are given at the hospital periodically: (1) examination of the eye; (2) the use of the ophthalmoscope; (3) errors of refraction; (4) external diseases of the eye; (5) surgical anatomy of the eye; (6) motor anomalies; (7) pathology of the eye; (8) practical pathology; (9) bacteriology; (10) operative surgery; and (11) X ray work. A composition fee of £10 10*s.* will entitle students of the hospital to a perpetual ticket, and will admit them once to all the above lectures and demonstrations except the classes on practical pathology, bacteriology, operative surgery, and X ray work. Students of the hospital are eligible for the offices of house surgeon or clinical and junior assistants. Junior assistants are appointed every three months. Any further information will be furnished by Mr. Robert J. Bland, Secretary.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand.—The hospital contains 40 beds. Out-patients, who number over 15,000 annually, are seen at 1 P.M., and operations are performed daily at about 3 P.M. The practice of the hospital is open to practitioners and students, men and women. Fees for six months, £3 3*s.*; perpetual, £5 5*s.*; shorter periods by arrangement. Students of the hospital are eligible for the posts of house surgeon, assistant house surgeon, pathologist, and clinical assistants. Secretary: Mr. John Hy. Johnson.

ROYAL EYE HOSPITAL, St. George's-circus, Southwark, S.E.—There are 40 beds and 2 cots. There were 56,097 attendances in the Out-patient Department last year, and the new patients numbered 19,198. Out-patients are seen daily 1.30 to 2.30 P.M. Dean: Mr. A. D. Griffith.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd-street, St. Pancras, W.C.—This hospital, which has lately been rebuilt, has 40 beds and possesses a well-equipped laboratory and every facility for clinical teaching daily. Last year there were 412 in- and 10,364 out-patients (entailing 28,097 attendances). The out-patient work begins at 1 o'clock, and operations are performed daily between 1 and 4. A scheme has lately been constituted and has received the recognition of the London University whereby students of the University College Hospital and other general hospitals in the neighbourhood will receive their ophthalmic training at the Central London Ophthalmic Hospital. Secretary: Mr. H. R. S. Druce.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, London, W., with which is amalgamated THE LONDON THROAT HOSPITAL, Great Portland-street.—The hospital contains 60 beds. There is an out-patient attendance of over 50,000 yearly. Clinical Instruction in the Diagnosis and Treatment of Disease is given in the out-patient department from 2 to 5 P.M., on Tuesdays and Fridays from 6.30 to 9 P.M. From amongst the students Junior Clinical Assistants are selected, whose duty it is to assist the member of the staff to whom they are appointed. For terms and further information apply to the Dean, Mr. Geo. W. Dawson.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road.—In addition to the new In-patient Department and operation theatre the hospital has a very extensive out-patient department, which is open to all medical practitioners and students for the purpose of clinical demonstration and instruction during the hours of the surgeons' visits. During the past year 10,248 out-patients (involving 40,000 attendances) and 616 in-patients were treated. The fee for three months' attendance is 5 guineas; for six months, 8 guineas. The post-graduate teaching consists of successive series of practical demonstrations by the members of the staff delivered twice weekly during the winter and summer sessions. They are so arranged that practitioners joining at any part of the course are enabled to complete the group of subjects. A special Operative Surgery class is held at intervals. The fee for each course is 2 guineas, with daily attendance at the out-patient department during the period of the course. Details of subjects, &c., will be afforded by the Dean. Considerable attention is given to scientific work, particularly with regard to Bacteriology of the ear and respiratory passages. Operation days: in-patients, Monday, Tuesday, Wednesday, Thursday, and Friday, at 2 P.M.; out-patients, daily at 9 A.M. The following appointments are open to qualified members of the profession:—Six Registrars, tenable for twelve months; and sixteen Clinical Assistants, tenable for three or six months. Secretary: Mr. Richard Kershaw.

THE METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL (1838) (incorporated).—The hospital was founded in 1838, and is situated in Fitzroy-square, W. The Out-patient Department is opened daily at 2.30 P.M. to all medical practitioners and senior students for acquiring clinical instruction and technical knowledge. Operations upon in-patients are performed on Tuesdays, Wednesdays, Thursdays, and Fridays at 10 A.M. Fee for one month's attendance at the hospital £1 1*s.*, and for three months £2 2*s.* Clinical Assistants are appointed as vacancies occur, and have responsible duties.

ROYAL EAR HOSPITAL, Dean-street, Soho. (Founded 1816.)—This hospital is at present handed over to the British Red Cross Society and will probably be retained by that society for the duration of the war.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM, City-road, E.C. (Founded 1835.)—The hospital contains 52 beds for men and women. Operations are performed on Mondays, Wednesdays, and Thursdays at 2.30 P.M. Medical practitioners and students are invited to the operations and to the clinical instruction in the wards and in the out-patient department. The number of out-patient attendances per year is 5000, and the average number of in-patients 670.

ST. PETER'S HOSPITAL FOR STONE AND OTHER URINARY DISEASES, Henrietta-street, Covent Garden. Established 1860. New Hospital opened 1882.—The hospital contains 30 beds for men and 2 beds for women and children. Medical practitioners and students are invited to the clinical instructions which are given in the wards and out-patient depart-

ment daily, and to the operations in the theatre on Wednesdays and Fridays at 2 P.M. Average beds occupied daily, 30; average out-patients seen daily, 125.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C. 2.—The in-patient department, 40 beds, is at 262, Uxbridge-road, W. The out-patient practice is open to the medical profession every day at 2 and every evening (except Saturday) at 6. At the afternoon clinics demonstrations on the different diseases presenting themselves are given. Venereal Diseases, under the Government scheme, are admitted at all clinics. The X ray department is open every afternoon except Saturday. The Chesterfield Lectures are given on Thursdays at 6 P.M., October to March, commencing Oct. 10th. At the end of the course the Chesterfield medal may be competed for by those who have attended three-fourths of the lectures. Special laboratory courses in Pathology and Bacteriology of the Skin may be arranged for.

LONDON LOCK HOSPITAL AND RESCUE HOME.—In the Female Hospital at Harrow-road, W., there are 159 beds, and 679 patients were admitted in 1917. In the Male Hospital and Out-patient Department in Dean-street, Soho, W., there are 43 beds, which during 1917 accommodated 435 patients. 36,500 out-patients were treated. 10,010 injections of the substitutes for salvarsan were made in 1917. Male patients are seen at Dean-street on Mondays from 1 to 2 P.M. and from 6 to 8 P.M.; on Tuesdays and Wednesdays from 6 to 8 P.M.; on Thursdays at 11.30 A.M. and 5.30–7 P.M. (female patients); on Fridays from 2 to 3 P.M. (female patients); and on Saturdays from 2 to 4 P.M. (males). Secretary: Henry J. Eason. Head office: 283, Harrow-road, W. 9.

ENGLISH PROVINCIAL ANCILLARY SCHOOLS AND HOSPITALS.

Under this heading we include all the hospitals which are recognised by the English Royal Colleges for a part of the required attendance on medical and surgical practice, for medical clerkships, and surgical dresserships. The list includes nearly every hospital of a general character in the country having more than 150 beds, though occasionally a large hospital is admitted because equally good opportunities are afforded to students at other institutions in its neighbourhood, while a small hospital may be included because no such facilities for study are present elsewhere. The list is arranged alphabetically as to the town where the hospital is located.

BATH ROYAL UNITED HOSPITAL, Bath.—This hospital contains 130 beds, and possesses a fine library. Secretary: Mr. J. M. Sheppard.

BEDFORD COUNTY HOSPITAL, Bedford.—This hospital has 100 beds, with X Ray and Pathological Departments. Secretary: Mr. Beauchamp Wadmore.

BRADFORD ROYAL INFIRMARY, Bradford.—This hospital contains 215 beds. The material passing through the Surgical wards consists of major operations, chiefly abdominal, and gynæcological work, and affords excellent facilities for either students or post-graduates. Plans for a new hospital of 382 beds have been adopted, and the building operations will be commenced as soon as the funds in hand will allow.

THE ROYAL SUSSEX COUNTY HOSPITAL, Brighton (265 beds).—This hospital affords ample facilities for students, possessing a large out-patient department, a library, and a well-appointed clinical research and bacteriological department. The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital for any period not exceeding two years on payment in advance of such a fee, not exceeding 20 guineas, as the Board of Management shall direct.

KENT AND CANTERBURY GENERAL HOSPITAL, Canterbury.—The hospital contains 110 beds. Pupils of the staff are admitted to the practice of the hospital and have the use of the library of the East Kent and Canterbury Medical Society for £7 7*s*. An X-ray apparatus has recently been given to the hospital. Operation day, Thursday, 11 A.M. Secretary: Mr. Arthur J. Lancaster.

DERBYSHIRE ROYAL INFIRMARY, Derby.—This hospital contains 260 beds. It was founded in 1810, and was entirely rebuilt and enlarged 1892–1915 on the most modern lines at a cost of over £144,000. There is a separate ophthalmic block of 33 beds, a separate children's block of 34 beds, and a special department for gynæcological cases. There are three resident house surgeons and a resident house physician. There is also a well-equipped Finsen light and X ray department. Registered medical students are admitted to witness the medical and surgical practice on payment of 10 guineas annually.

ROYAL DEVON AND EXETER HOSPITAL, Exeter.—The hospital contains 200 beds (including special children's ward) and has a good library, museum, dissecting room, and post-mortem room. Attendance on the practice of this hospital qualifies for all the examining boards. There is also a Private Nursing Staff attached to the hospital. For particulars as to fees, &c., apply to the Matron. A new wing was added in 1897. Arrangements may be made by which gentlemen in practice desiring to increase their qualifications may have the use of the museum and library and other facilities and by which students may attend midwifery. A new Operating Theatre was opened in 1906 (the gift of Mrs. Nosworthy of Newlands, Dawlish, Devon). The Electrical Treatment Department (the gift of Mrs. M. A. Sanders) was opened in 1907 by Lady Duckworth-King. A department was opened in 1917 for the treatment of genito-urinary diseases; there are three sessions per week, two for men at 4 P.M. and 7 P.M., and one for women at 4 P.M.

WEST OF ENGLAND EYE INFIRMARY, Exeter.—Secretary: Mr. W. W. Beer. The infirmary contains 64 beds. Students of the Exeter Hospital can attend the practice of the Eye Infirmary. Patients for the year ending Michaelmas, 1917, 2537.

THE GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION, Gloucester.—This hospital, which was granted the title of "Royal" on the occasion of King Edward VII.'s visit to Gloucester in the year 1909, has 140 beds. Secretary: Mr. H. P. Pike. In-patients, 1780; out-patients, 7018.

NORTH STAFFORDSHIRE INFIRMARY, Hartshill, Stoke-on-Trent.—The New Infirmary, opened in 1869, is built on the pavilion plan, has accommodation for about 240 patients, including Children's wards, and a special department for the treatment of Diseases of the Eye, a special X Ray and Electrical Department, and a special department for the treatment of Diseases of the Ear, Nose, and Throat, so that there are excellent facilities for acquiring a practical knowledge of the profession. During the last six years the sum of £35,000 has been spent on new buildings and alterations. A new Out-patient Department, costing £12,000, a new Children's Ward of 30 beds, a new Pathological Department, and a second large Operation Theatre are amongst the structural improvements already completed. The whole institution is now equipped in a thoroughly up-to-date manner. Secretary and House Governor: Mr. W. Stevenson.

HULL ROYAL INFIRMARY, Hull.—This hospital contains 256 beds.

LEICESTER ROYAL INFIRMARY, Leicester.—Instruction in the infirmary for first-year students is duly recognised by the various examining bodies. At the General Infirmary there are 230 beds, and at the Children's Hospital in connexion 70; total 300. 126 beds have been placed at the disposal of the War Office for wounded soldiers. A new wing containing 100 beds was recently opened by H.R.H. the Duchess of Argyll, and a new Nurses' Home containing separate accommodation for 100 nurses has also been opened. A reconstruction scheme has been carried out, and £120,000 spent on bringing the accommodation of the institution to a modern standard of efficiency. This scheme has included the provision of two modern operating theatres, and a self-contained out-patients' department. The Children's Hospital has been reconstructed and enlarged by the addition of a third ward at a cost of £14,500. Open-air balconies on all three floors are a feature. A central sterilising department has been provided. Plans have been passed for a new Pathological Laboratory and post-mortem rooms at an estimated cost of £5000. There are eight resident medical officers—viz., two house surgeons, one house physician, two assistant house surgeons, one assistant house physician, and two dressers. All receive salaries. The dressers are given an honorarium. House Governor and Secretary: Mr. Harry Johnson.

NORTHAMPTON GENERAL HOSPITAL, Northampton.—Two new wings were opened in 1904 and the old buildings entirely renovated and rearranged. The number of beds is 298, 120 of which are occupied by wounded soldiers. Non-resident pupils are received and have every opportunity of acquiring a practical knowledge of their profession. The fee is £10 10*s*. Pupils can be received at any time.

NORFOLK AND NORWICH HOSPITAL, Norwich.—This hospital has at present 425 beds (150 civilian, 275 military). Non-resident pupils admitted. Fees: For three months. £3 3s.; for six months, £5 5s.; as permanent pupil, £8 8s. Secretary: Mr. F. Inch.

NOTTINGHAM GENERAL HOSPITAL.—At the present time there are 233 beds available for civilian patients, and 300 for the accommodation of sick and wounded soldiers from overseas, including 200 in temporary buildings which have been erected within the hospital grounds for this purpose.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth.—This hospital contains 189 beds (25 of which are allocated for wounded soldiers). A new mortuary chapel has been recently erected.

THE ROYAL HOSPITAL, Portsmouth (founded 1847).—The number of beds is 160. The hospital has X Ray and Massage Departments. The hospital is a preparatory School of Medicine and Surgery; the attendance of pupils at this hospital is recognised by the Examining Boards. Particulars of the Secretary at the hospital.

ROYAL BERKSHIRE HOSPITAL, Reading.—This hospital, which contains 264 beds, with military wards, has been recently enlarged, the additions including a new Out-patient Department, a Casualty Department, an X Ray Department, a Laboratory, an Eye Theatre, and Eye Wards.

SALISBURY GENERAL INFIRMARY, Salisbury.—This hospital contains 200 beds. In-patients, 169 daily average; out-patients, 644, including ophthalmic cases 208 and X ray cases 943; attendances on 3728 casuals. Secretary, Mr. S. B. Smith.

ROYAL SALOP INFIRMARY, Shrewsbury.—This hospital has 160 beds. In-patients, 1264; out-patients, 981; out-patients' attendances for the year, 16,326. Secretary: Mr. Alfred Sugden.

ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL, Southampton.—This hospital contains 130 beds. In-patients, 2310; out-patients, 8297. Secretary: Mr. T. A. Fisher Hall.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—This hospital has 77 beds. In-patients, 880; out-patients, 2614. Secretary: Mr. R. Battle.

ROYAL HANTS COUNTY HOSPITAL, Winchester.—This hospital has 108 civilian and 240 military beds. Secretary: Mr. Edwin J. Pearce.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—There are 262 beds. Special departments for Children, Gynæcology, Ear, Throat, and Nose Diseases, Electro-therapeutic and X ray and Pathological departments. There is an excellent library. The resident officers are a resident medical officer and three house surgeons. Pupils are allowed to witness the whole of the practice of the hospital and to be present at operations and have every opportunity of acquiring a practical knowledge of their profession. Fees: £3 3s. a quarter, £10 10s. the first year, and £5 5s. subsequent years. A course of Practical Pharmacy is given by the dispenser. Fee £3 3s. for three months. Applications should be made to the Secretary of the Medical Committee.

WORCESTER GENERAL INFIRMARY, Worcester.—This hospital has 132 beds (temporarily reduced to 70). Pupils are taken by members of the Honorary Medical and Surgical Staff. Number of operations last year 1308. New X Ray and Electrical Departments have been recently erected and are now in use. Additional accommodation for the Honorary Staff and Out-patients and also an Outdoor Shelter in connexion with the Children's Ward have been built as a memorial to King Edward VII. In-patients, 1014; out-patients, 3098. Secretary: Mr. E. J. Holland.

YORK COUNTY HOSPITAL, York.—This hospital contains 230 beds, of which 110 are reserved for military patients. There are balconies for outdoor treatment and two installations of X Ray apparatus.

SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The subjects of the Minor examination of the Pharmaceutical Society (for registration as "chemist and druggist") are botany, chemistry and physics, practical chemistry, materia medica, pharmacy, practical pharmacy and dispensing, and prescription reading. Fee, 10 guineas; for each subsequent examination after failure, 3 guineas. The advanced or Major examination (for registration as "pharmaceutical chemist") includes botany, chemistry and physics, practical chemistry, and materia medica. Fee, 3 guineas. The inaugural address will be delivered on Wednesday, Oct. 2nd. Medical students are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in this school are received by the Conjoint Board of the Royal Colleges and by the University of London. Application for admission to the school, or for further information, may be made to the Dean, Professor Greenish, 17, Bloomsbury-square, London, W.C. 1.

II.—SCOTLAND.

THE UNIVERSITIES.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degree of Bachelor of Surgery cannot be conferred on any person who does not at the same time obtain the degree of Bachelor of Medicine, and similarly the degree of Bachelor of Medicine is not conferred on any person who does not at the same time obtain the degree of Bachelor of Surgery.

No one is admitted to the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* who has not been engaged in Medical and Surgical study for five years. No course of lectures will be allowed to qualify unless the lecturer certifies that it has embraced at least 100 lectures, or 50 lectures, as may be required by the regulations, and that the student has also duly performed the work of the class.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons. They must have attended Clinical Surgery during a course or courses extending over not less than nine months, and courses of instruction in all the subsidiary subjects. They must have personally conducted, under the superintendence of a registered medical practitioner, 20 cases of labour at least.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations have effect:—Two of the five years of medical study must be spent in the University of Edinburgh. The remaining three years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign university recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Of the subjects of study—viz., Anatomy, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica, Physiology, Practical Physiology, Practice of Medicine, Surgery, Midwifery and Diseases of Women, Pathology, Practical Pathology, Physics, Botany, Zoology, Medical Jurisprudence, and Public Health—not less than one-half must be taken in the University of Edinburgh, which corresponds to the two years above referred to.

Women are admitted to graduation in medicine under practically the same conditions as men.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is £23 2s., and the proportion of this sum to be paid by a candidate at each division of the examination shall be as follows—viz.: For the First Division of the Examination (Botany, Zoology, Physics, and Chemistry), £6 6s.; for the Second Division (Anatomy and Physiology), £5 5s.; for the Third Division (Pathology and Materia Medica and Therapeutics), £4 4s.; and for the Final Division (Surgery and Clinical Surgery, Medicine and Clinical Medicine, Midwifery, Clinical Gynæcology, and Forensic Medicine and Public Health), £7 7s.

Bachelors of Medicine and *Bachelors of Surgery* may proceed to the degrees of *Doctor of Medicine* and *Master of Surgery* after they have spent one year in the medical or surgical wards respectively of a hospital, or the Military or Naval Medical Services, or in scientific work bearing directly on their profession, or two years in practice. In each case an examination must be passed and a thesis

submitted for approval of the Faculty. The fee to be paid for the degree of M.D. is £15 15*s*., and the fee to be paid for the degree of Ch.M. is £15 15*s*.

A diploma in Tropical Medicine and Hygiene (D.T.M. and H.) is granted to graduates in Medicine and Surgery of the University of not less than six months' standing, and to Registered Medical Practitioners who, having resided in a tropical country, may be approved by the Senatus, on the recommendation of the Faculty of Medicine.

Diploma in Psychiatry.—Courses of instruction have also been instituted for a Diploma in Psychiatry, open to all legally qualified Medical Practitioners who conform with the Regulations. There shall be two examinations for the Diploma, the first comprising the subjects of Anatomy of the Nervous System; Physiology, Histology, and Chemistry of the Nervous System; Pathology of the Brain and Nervous System; and Practical Bacteriology in its relation to Mental Diseases; and the second examination comprising the subjects of Psychology with Experimental Psychology, Clinical Neurology, and Psychiatry (systematic and clinical). The fee for each examination shall be £5 5*s*.

The University of Edinburgh is especially rich in scholarships and prizes in medical subjects. Full particulars can be obtained from the Dean of the Medical Faculty.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh.—The number of students varies much in the classes and subjects. It is within the limit to say that before the war about 1000 students availed themselves each session of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of London, Edinburgh, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards.

The anatomy rooms and laboratories will open and the lectures commence on Oct. 9th.

In accordance with the statutes of the University of Edinburgh one-half of the qualifying classes required for graduation may be attended in this school. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

The courses on special non-qualifying subjects have for the last quarter of a century formed a marked feature of the school. Indeed, such medical subjects could be studied in Edinburgh only in this school until lately, when the University of Edinburgh appointed from the school lecturers on Diseases of the Eye, Insanity, and Diseases of Children to take charge of classes intra-murally. Special courses of instruction for dental students and for women are also included in the curriculum of this school.

The minimum cost of the education in this School of Medicine for the Triple Qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the Joint Examinations, is about £120, payment of which is distributed over the period of study. There is no composition fee.

Further particulars regarding the school, also its calendar, may be had on application to the Dean of the School, 11, Bristo-place, Edinburgh.

Clinical Instruction.—ROYAL INFIRMARY, Edinburgh.—This hospital has 921 beds and 42 cots for children. Courses of Clinical Medicine and Surgery are given by the physicians and surgeons to male and female students. Special instruction is given on Diseases of Women, Physical Diagnosis, Diseases of the Skin, Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, Throat and Nose, and the Skin, and also to cases of Incidental Delirium or Insanity. There are also large and complete Medical-Electrical and X Ray and Bathing Departments. Post-mortem examinations are conducted in the anatomical theatre by the pathologist and his assistants, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6*s*.; six months, £4 4*s*.; three months, £2 2*s*.; monthly, £1 1*s*. Separate payments amounting to £12 12*s*. entitle the student to a life ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows: 1. Resident physicians and surgeonsare appointed and live in tha house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident house physicians and surgeons and clinical assistants are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department are appointed by the pathologist.

ROYAL HOSPITAL FOR SICK CHILDREN, Sciennes-road, Edinburgh.—This hospital contains 120 beds, and is fitted with every modern improvement. A fully equipped out-patient department (medical and surgical) is conducted daily in a building adjoining the hospital. Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given from time to time throughout the year by the staff. Students may enter at any time. Full particulars can be obtained from the Registrar at the hospital.

EYE, EAR, AND THROAT INFIRMARY OF EDINBURGH, 6, Cambridge-street, Lothian-road.—Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for outdoor patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon, and Tuesdays and Fridays at 4 P.M. for outdoor Ear, Nose, and Throat Patients. Special Practical Ophthalmoscopic Classes by arrangement. Patients whose diseases require operations or more than ordinary care are accommodated in the house. Secretary: Mr. J. P. Watson, W.S., 32, Charlotte-square.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but not less than one-half of the subjects other than clinical must be taken in this or some other recognised university, and at least two years of the course must be taken in Glasgow University. Six degrees, open both to men and women, are conferred: M B. and Ch.B. (always conjointly), M.D. and Ch.M.; B.Sc. in Public Health; D.Sc. in Public Health; and B.Sc. in Pharmacy. A Preliminary Examination must be passed in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek, or French, or German, or Italian, with possible options to students whose native language is not English. Candidates taking the University preliminary examination are not obliged to pass in all the four subjects at one examination, but must do so at not more than two occasions.

For the degrees of M.B. and Ch.B. a curriculum of five years is required. The candidate must, during his curriculum, have attended a course or courses of instruction in each of the following subjects of study, extending over not less than the number of terms specified in each case, and including such class examinations as may be prescribed in connexion with the several courses:—Chemistry (including Organic Chemistry), two terms; with Practical Chemistry, one term; Physics (with practical work), one term; Botany (with practical work), one term; Zoology (with practical work), one term; Anatomy and Practical Anatomy, five terms; Physiology and Practical Physiology, three terms; Materia Medica and Therapeutics (together or separately), each subject, one term; Pathology and Practical Pathology, three terms; Medical Jurisprudence and Public Health (together or separately), each subject, one term; Midwifery and Diseases peculiar to Women and to Infants, two terms; Surgery, two terms; Medicine, two terms. Candidates must attend at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine, and the student must have acted for six months as clerk in medical and dresser in surgical wards, and must have had six months' outdoor practice; he must

also have attended a course of Mental Diseases and of Practical Pharmacy (25 meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least 20 cases of labour and the Practice of a Lying-in Hospital. The University also requires further study in various special subjects.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry; the second comprising Anatomy and Physiology; the third comprising Materia Medica and Therapeutics and Pathology; and the fourth or final, comprising Medical Jurisprudence and Public Health, Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and the Diseases peculiar to Women and to Infants.

The degrees of M.D. (Doctor of Medicine) and Ch.M. (Master of Surgery) are higher degrees in Medicine and Surgery respectively, and candidates (not under 24 years of age) who have previously obtained the double bachelorship may be admitted to either M.D. or Ch.M. on completing the after course prescribed, including an examination in Clinical Medicine for M.D. and an examination in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M.

Fees.—The Fees for M.B. and Ch.B. are £23 2*s*. The class fee in each subject of the curriculum for M.B. and Ch.B. is £2 2*s*., £3 3*s*., or £4 4*s*., and the present fee for hospital attendance is £7. The fee for M.D. is £15 15*s*., and for Ch.M. £15 15*s*.

The great majority of the students take their hospital course at the Western Infirmary, or the Royal Infirmary, where clinical instruction is given by professors of the University and others. Clinical instruction on Fevers is given at Ruchill and Belvidere Hospitals, while special courses, largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Ear, the Throat and Nose, Dermatology, Ophthalmology, Venereal Diseases, and Insanity. Queen Margaret College, sometime conducted as a separate institution for the higher education of women, was made over to the University in 1892, and in it medical classes for women are conducted under University professors and other lecturers appointed by the University Court, whilst for clinical instruction female students are admitted to the Royal Infirmary.

In this University Bursaries and Prizes to the annual amount of over £1000 are appropriated to students in the Medical Faculty, and there are also several Scholarships and Fellowships which may be held by medical students who have gone through the Arts course. A full list will be found in the University Calendar.

THE ANDERSON COLLEGE OF MEDICINE, Dumbarton-road, Glasgow, W.—Courses are given which qualify for all the licensing boards and for the Universities of London, Durham, Edinburgh, and Glasgow (the latter two under certain conditions). Candidates for the Licence in Dental Surgery can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are also conducted in the Anderson College of Medicine.

The buildings are situated in Dumbarton-road, immediately to the west of the entrance to the Western Infirmary, and adjoining the University. Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Botany, Practical Zoology, Practical Physiology, Practical Pharmacy, Operative Surgery, and Public Health. Ample provision has also been made for the comfort of students.

Women students are admitted on the same terms as men.

The Carnegie Trust extends its benefactions to students of the Anderson College of Medicine. Full particulars may be obtained from Sir W. S. McCormick, the Carnegie Trust Offices, Merchants' Hall, Edinburgh.

Communications relating to the College to be addressed to the Secretary of the Medical Faculty, The Anderson College of Medicine, Glasgow, W. Communications relating to the Preliminary Examination in General Education to be addressed to Mr. Hugh Cameron, M.A., F.E.I.S., Educational Institute Office, 34, North Bridge-street, Edinburgh. Communications relating to the Triple Qualification to be addressed to Mr. Walter Hurst, Royal Faculty Hall, 242, St. Vincent-street, Glasgow.

The Winter Session will open on Monday, Oct. 14th, 1918, and will close on Thursday, March 20th, 1919.

The Summer Session will open on Wednesday, April 23rd, 1919, and will close on Wednesday, July 2nd, 1919.

ST. MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY.—The classes in St. Mungo's College qualify for the English, Scotch, and Irish Conjoint Boards and, under certain conditions, for the various universities, including the University of London. Students who have fulfilled the conditions of the Carnegie Trust as regards Scottish birth or extraction, age (16 years), and Preliminary Examination, are eligible for the benefits of this Trust during the whole course of their studies at St. Mungo's College. The classes are open to male and female students equally. The minimum fees for all the lectures, including hospital attendance, necessary for candidates for the Diplomas of the English or Scotch Colleges of Physicians and Surgeons, amount to £65. Further particulars can be obtained from a syllabus which may be procured free on application to the Secretary of the Medical Faculty, 86, Castle-street, Glasgow.

GLASGOW WESTERN MEDICAL SCHOOL.—This School is closed during the war.

QUEEN MARGARET COLLEGE, University of Glasgow (Women's Department of the University).—The classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curriculum, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. They have access to the University Museum and can borrow books from the University Library, besides having a library of reference in Queen Margaret College. The School of Medicine is a special feature of the College, and gives full preparation for the medical degrees of the University. In July, 1894, for the first time in the history of any Scottish University, women students graduated in medicine in Glasgow University. 253 women have now taken the degree of M.B., C.M., or M.B., Ch.B. of the University of Glasgow and 24 the degree of M.D. The women students attend classes in the various University Buildings at Gilmore-hill, Queen Margaret College, and the Royal Infirmary. Excellent facilities for clinical work are given in the Royal Infirmary, in the Maternity, and other hospitals. The Arthur Scholarship is open every third year to students of first year; other Bursaries are open in Arts and Medicine; and by an ordinance of the Universities Commissioners women are admitted to certain University bursaries, scholarships, and fellowships. There is a house of residence for the students of the College coming from a distance. The Winter Session will open on Oct. 15th.

ROYAL INFIRMARY, Glasgow.—The ancient connexion between the University of Glasgow and the Royal Infirmary was revived in 1911, when four University Chairs and several University Lectureships were established at the infirmary. St. Mungo's College is situated in the infirmary grounds. The infirmary has, including the Ophthalmic Department, 835 beds. There are special beds and wards for diseases of women, of the throat, nose, and ear, skin, venereal diseases, burns and septic cases. The wards are open to Women Students. At the Out-door Department the attendances in 1917 numbered almost 136,000. In addition to the large medical and surgical departments there are departments for special diseases—viz., diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. Five house physicians and 12 house surgeons, having a legal qualification in medicine and surgery, who board in the hospital free of charge, are appointed every six months. Clerks and dressers are appointed by the physicians and surgeons. As a large number of cases of acute diseases and accidents of a varied character are received these appointments are very valuable and desirable. There is a modern and fully equipped Electrical Pavilion, and year by year the latest and most approved apparatus for diagnosis and treatment has been added. The fees are as follows: (*a*) For hospital practice, including attendance at the out-door department, at the pathological department, post-mortem examinations, and the use of the museum: Perpetual ticket, £7; six months, £2 2*s*.; three months, £1 1*s*.; separate payments amounting to £7 7*s*. entitle the student to a perpetual ticket, on return of previous season tickets;

(*b*) for Clinical Lectures, six months, £3 10*s.*; three months, £1 15*s.*; (*c*) Vaccination, £1 1*s.*; Pathology, £4 4*s.*; Bacteriology, £2 2*s.*

GLASGOW WESTERN INFIRMARY.—This hospital adjoins the University of Glasgow. Number of beds upwards of 600. Special wards are set apart for Diseases of Women and for Affections of the Skin. In the out-patient department there are special cliniques for Diseases of Women and for Diseases of the Throat, Ear, Teeth, and Skin. The Clinical Courses are given by the physicians and surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department the course is both systematic and practical, also post-graduate courses, and extends through the winter and following summer; these are likewise recognised by the University for graduation. Fifteen resident assistants are appointed annually, without salary, from those who have completed their course. The fee for hospital attendance is £7, and the fees for clinical instruction are £3 3*s.* for the Winter Session and £2 2*s.* for the Summer Session. A Clinical Laboratory has been opened, and students receive laboratory instruction from the lecturer on clinical methods. Secretary: J. Matheson Johnston, C.A., 87, Union-street.

A School of Massage, Medical Electricity, and Swedish Remedial Exercises has been established to qualify for the Certificate of the Incorporated Society of Trained Masseuses.

ROYAL HOSPITAL FOR SICK CHILDREN, Yorkhill, Glasgow.—This institution, which was founded in 1882, consists of: (1) a hospital at Yorkhill containing 204 cots built on an elevated and central site close to the University and opened in July, 1914; (2) a Dispensary, or Out-patient Department, in West Graham-street, opened in October, 1888; and (3) a country branch at Drumchapel, Dumbartonshire, containing 24 cots, opened in 1903. Children treated must be under 12 years of age and suffering from non-infectious diseases. In the hospital, part of which is at present used as a military hospital for officers, about 5000 children are treated annually. In the Out-patient Department over 12,000 are treated annually, involving nearly 50,000 attendances. Information with regard to clinical instruction, lectures, demonstrations, &c., may be obtained from the Medical Superintendent.

GLASGOW ROYAL MATERNITY AND WOMEN'S HOSPITAL, Rotten-row.—The new hospital which was opened in 1908 is in point of size the largest of its kind in Britain and has accommodation for 108 patients. A Maternity and Child Welfare Centre has been established in connexion with the hospital, consisting of a complete In-door and Out-door Ante-natal Department and an Infant Consultation Clinic. In 1917 2222 normal cases and 1291 abnormal cases were treated by the hospital in the In-door and Out-door Departments. Secretary: Mr. William Guy, 146, Buchanan-street. Full particulars as to fees and accommodation may be obtained from the House Superintendent at the Hospital.

GLASGOW LOCK HOSPITAL, Rotten-row.—The Hospital contains 83 beds. During 1917 786 patients were admitted to the wards; 5768 visits were made by out-door patients at the Dispensary. Classes are held for the clinical instruction of medical students and practitioners.

GLASGOW OPHTHALMIC INSTITUTION, 126, West Regent-street (29 beds and six cots).—Clinical and systematic course of lectures for students during the winter and summer sessions. In-patients, 825; out- or dispensary patients, 12,859; total attendances, 46,691. Operations on Wednesdays and Saturdays. This institution is the Ophthalmic Department of the Royal Infirmary. Clinical instruction is given during both summer and winter sessions to men and women students attending the University. Secretary and Cashier: R. Morrison Smith, C.A., 135, Buchanan-street, Glasgow.

GLASGOW EYE INFIRMARY, Berkeley-street and Charlotte-street.—This institution, the largest of its kind in Scotland, was founded in 1824. The average number of new patients for the last ten years has been 26,402 and the total number of cases in 1917 was 26,937. The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine. Secretary and Acting Treasurer: Harold John Black, 88, West Regent-street, Glasgow. Superintendent: James H. Archibald. The medical session opens in October. A Post-graduate Class will be held.

GLASGOW HOSPITAL FOR DISEASES OF THE EAR, NOSE, AND THROAT, 27, and 28, Elmbank-crescent.—12 beds and two cots. New patients, 3888. Attendances at out-patient department 14,956. Admitted to in-door department 325. Clinical instruction is given in connexion with Dr. Connal's course on Diseases of the Ear at Anderson's College and Dr. Syme's course on Diseases of the Throat and Nose at the Western Medical School.

UNIVERSITY OF ST. ANDREWS (UNITED COLLEGE, ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE).

Four degrees in Medicine and Surgery are conferred by the University of St. Andrews—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), a Diploma in Public Health, and Diploma in Dental Surgery (L.D.S.). The whole curriculum may be taken at University College, Dundee, or the first two years of the course may be taken at St. Andrews and the remaining three years in Dundee. The degrees of M.B. and Ch.B. shall always be conjoined. Before commencing his medical studies each student shall pass a Preliminary Examination in (*a*) English, (*b*) Latin, (*c*) Elementary Mathematics, and (*d*) one of the following optional subjects: (α) Greek, (β) French, (γ) German, (δ) Italian, (ε) any other approved Modern Language. A degree in Arts or in Science in any of the Universities of the United Kingdom and in some colonial and foreign universities shall exempt from the Preliminary Examination. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science and the Final Examination for the Diploma of LL.A.

Degree of Bachelor of Medicine and Bachelor of Surgery.—Candidates must have been engaged in medical study for at least five years. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz.: Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants. Pathology, Practical Chemistry, Physics (including the Dynamics of Solids, Liquids, and Gases, and the Rudiments of Sound, Heat, Light, and Electricity), Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons and is recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery, Operative Surgery, Vaccination, Children's Diseases, Fevers, Ophthalmology, Diseases of the Ear, Throat, and Nose, Anæsthetics, and Post-mortem Examinations.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the

University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Women are admitted to graduation in Medicine, subject to certain provisions.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate will be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., first, in Botany, Zoology, Physics, and Chemistry; second, in Anatomy and Physiology; third, in Materia Medica and Pathology and Forensic Medicine and Public Health; and fourth, in Surgery, Clinical and Operative Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and Gynæcology (Systematic and Clinical).

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery shall be 22 guineas, and the proportion of this sum to be paid by a candidate at each division of the examination shall be regulated from time to time by the University Court. The fee to be paid for the degree of Doctor of Medicine shall be 15 guineas, and for the degree of Master of Surgery 15 guineas. The whole medical curriculum can be taken in University College, Dundee, or the first two years in United College, St. Andrews.

For further particulars and details as to scholarships and bursaries application should be made to Professor Kynoch, Dean of the Medical Faculty, University College, Dundee.

UNIVERSITY COLLEGE, Dundee.—This College is one of the constituent colleges of the University of St. Andrews. In the medical buildings there are spacious and well-equipped laboratories. The complete medical curriculum can be taken in Dundee. For classes, fees, &c., see under University of St. Andrews.

ROYAL INFIRMARY, Dundee.—The Infirmary contains 408 beds, including special wards for the Diseases of Women, Children, Eye, Ear, and Throat, Skin, and for Obstetric cases. There is in addition an Extern Obstetric Department. There were during last year 13,464 out-patients and 354 home (maternity) patients. The Royal Infirmary offers exceptional facilities for practical work to students. Appointments: Six qualified Resident Medical Officers (Male or Female) are appointed every six months and one non-resident Obstetric Assistant. Clinical Clerks and Dressers are attached to the Physicians and Surgeons, and students are appointed as assistants in the Pathological Department. There are in connexion with the clinical courses Tutorial Classes in Medicine and Surgery. Instruction is also given in Practical Pharmacy and Materia Medica. Further information can be obtained from the Medical Superintendent.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen grants four degrees in Medicine and Surgery—viz., Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Medicine (M.B.), and Bachelor of Surgery (Ch.B.).

Degrees of M.B. and Ch.B.—Before commencing his medical studies each student must pass a Preliminary Examination in (1) English, (2) Latin, (3) Mathematics, and (4) Greek, or French, or German. The curriculum for the degrees extends over a period of five years, during which attendance is required in the following subjects: Botany, Zoology, Physics, Chemistry (Systematic and Practical), Anatomy (Systematic and Practical), Physiology (Systematic and Practical), Materia Medica and Therapeutics, Practical Pharmacy, Pathology (Systematic and Practical), Medical Jurisprudence, Public Health, Surgery, Medicine, and Midwifery.

Candidates must attend for at least three years the medical and surgical practice of a recognised hospital; they must have attended courses of at least nine months in clinical medicine and clinical surgery, and have acted as clerk in the medical and dresser in the surgical wards of a hospital. Attendance is required on the practice of a dispensary or the out-practice of a hospital and also on courses in Mental Diseases, Fevers, Ophthalmology, Post-mortem examinations, Venereal Diseases, and other special subjects. The candidate is also required to have been properly instructed in Vaccination and to have attended at least 20 Midwifery cases.

The fee for the degrees of M.B. and Ch.B. amounts to £23 2*s*.

Besides the Royal Infirmary (270 beds), students have the opportunity of attending the following institutions: City Fever Hospital, Sick Children's Hospital, General Dispensary, and Lying-in and Vaccine Institutions, Royal Lunatic Asylum, Ophthalmic Institution, &c.

Degrees of M.D. and Ch.M.—Candidates for either of these degrees must already hold the degrees of M.B. and Ch.B. of Aberdeen. A thesis has to be presented and an examination has to be passed in Clinical Medicine (or in some special Department of Medical Science) or Clinical Surgery, as the case may be.

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination.

Application for further information should be addressed to the Secretary of the Medical Faculty.

Scholarships and Prizes.—In the Faculty of Medicine of the University of Aberdeen there are the following Bursaries, Scholarships, and Prizes:—Bursaries: about 15 Bursaries (competition and presentation) are open each year, of £15 to £30 per annum in value, most of them being tenable for three years. Scholarships: five Post-Graduate Scholarships, value £36 to £160 per annum. Prizes and Medals: 13 Gold Medals and Prizes for proficiency in special departments, &c.

Clinical Instruction is given in the Aberdeen Royal Infirmary (270 beds) by the physicians and surgeons on the staff.

ABERDEEN ROYAL ASYLUM.—Contains, with hospital attached to main institution and agricultural branch, about 986 beds. Clerk and Treasurer, Mr. A. Scott Finnie, 343, Union-street, Aberdeen. Clinical instruction is given to students during three months in summer.

SCOTTISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or Glasgow, or both, the student may obtain the diplomas of the three Bodies.

The three Bodies grant their Single Licences only to candidates who already possess legal qualifications in Medicine or Surgery. Copies of the Regulations for the Single Licence of any of the Bodies may be had on application to the respective secretaries.

Professional Education.—The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of instruction: Physics, three months; Elementary Biology, three months; Chemistry, six months; Practical or Analytical Chemistry, three months; Anatomy, during at least six months; Practical Anatomy, twelve months; Physiology, six months; Practical Physiology, three months; Materia Medica, three months; Pathology (including Practical Pathology), nine months; Practice of Medicine, six months; Clinical Medicine, nine months; Principles and Practice of Surgery, six months; Clinical Surgery, nine months; Midwifery, three months; Gynæcology, one course of not less than 13 meetings; Diseases of Children, one course of not less than 13 meetings. Medical Jurisprudence and Public Health, three months. The certified attendance on lectures, demonstrations, and practical work must not be less than three-fourths of the total number of roll-calls. Every student undergoes a course of Practical Midwifery, but before attending at labours he is required to attend a course of lectures on Surgery and Midwifery and to hold the offices of Clinical Medical Clerk and Surgical Dresser. He must also attend for two and a half months instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy.

The student must attend for 27 months the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction and possessing distinct staffs of physicians and of surgeons. He must act as Surgical Dresser and Medical Clinical Clerk for not less than six months in the wards in each case, and receive practical instruction in administration of anæsthetics. He must attend for six months the practice of a public dispensary especially recognised by any of the above authorities, or the out-patient practice of a recognised general hospital or act for six months as pupil to a registered practitioner who either holds such a public appointment, or has such opportunities of imparting practical knowledge as shall be satisfactory to the coöperating authorities; this attendance should be made after the student has passed the First and Second examinations.

Candidates are also required to attend the following courses: Diseases and Injuries of the Eye, three months; Insanity, three months; Infectious Diseases, three months; Gynæcology, three months; Diseases of Children, three months.

The curriculum lasts for five years, the fifth year being devoted to clinical work.

There are four professional examinations:—

First Examination includes Physics, Chemistry, and Elementary Biology.

Second Examination includes Anatomy and Physiology and Histology; and candidates may be admitted to this examination at the end of the second year of medical study.

Third Examination includes Pathology and Materia Medica with Pharmacology.

Final Examination.—The Final examination shall not be taken earlier than the end of the fifth year of study and shall embrace the following subjects:—Medicine, including Therapeutics, Medical Anatomy, and Clinical Medicine; Surgery, including Surgical Anatomy, Clinical Surgery, and Diseases and Injuries of the Eye; Midwifery and Diseases of Women; and, if not passed previously, Medical Jurisprudence and Public Health, but it is optional to candidates who have passed the Third Examination to be admitted to the subject of Medical Jurisprudence and Public Health on lodging certificates of having attended the necessary course in that subject at any time; but the subjects of Medicine, Surgery, and Midwifery shall be taken together at any time after the end of the fifth Winter Session, provided that a period of 24 months has elapsed since passing the Second Examination. All candidates shall be subjected, in addition to the written and oral examinations, to clinical examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface Markings, &c. The fees payable for the Final Examination shall be—for the whole examination, £15, for re-entry after rejection, £5, and for the subjects of Medical Jurisprudence and Public Health when taken separately, £5, with £3 for re-entry in that subject.

There are four periods of examination annually during the period of the war, three in Edinburgh and one in Glasgow, in 1918–19. The Registrar in Edinburgh is Mr. D. L. Eadie, 50, George-square, and the Registrar in Glasgow, Mr. Walter Hurst, 242, St. Vincent-street, to whom fees and certificates must be sent for the respective examinations, and from whom further particulars concerning fees can be obtained.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH: THE MEMBERSHIP AND FELLOWSHIP.

In addition to the diplomas granted by the Scottish Conjoint Board the Royal College of Physicians grants its Single Licence to candidates already possessing legal qualifications for professional practice.

The Royal College of Physicians of Edinburgh grants a *Membership* and a *Fellowship*.

Membership.—A candidate, who must be a Licentiate of a British or Irish College of Physicians, or a graduate in medicine of a University within the British Empire, approved by the Council and 24 years of age, is examined in medicine, therapeutics, and in any branch of the departments of medicine specially professed, such as general pathology, psychology, public health, obstetrics, gynæcology, diseases of children, tropical medicine, or medical jurisprudence. The fee for the Membership is £36 15*s*., 15 guineas of which will be returned to any successful candidate who was already a Licentiate of the College at the time of qualifying for the Membership.

Fellowship.—The Fellows are selected from the ranks of the *Members*. The fee is £64 18*s*.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH: THE FELLOWSHIP.

The Royal College of Surgeons of Edinburgh also admits to the examination for its Single Licence any candidates who hold a Diploma in Medicine of any British, Indian, or Colonial university or of any British or Colonial College of Physicians, or of the Society of Apothecaries of London or Apothecaries' Hall, Dublin, granted under the provisions of the Medical Act, 1886, whose preliminary examination and course of professional study is proved to be sufficient to fulfil the requirements of the College, or to those who have passed a full examination for any of the above. Female practitioners are now admitted to the Licence of the College but not to the Fellowship, and the regulations for the Licence apply to practitioners of either sex.

The Royal College of Surgeons of Edinburgh grants a diploma of Fellowship after examination to the holders of the surgical degrees of diplomas of such British examining bodies, as well as of the holders of such surgical degrees of the Universities of Canada, Australia, New Zealand, and the Indian Empire as are recognised by the College.

The Fellowship.—Candidates for the examination must be 25 years of age and must have been engaged in practice for at least two years. The examination is of a practical nature, partly written and partly *viva voce*, and must include surgery and surgical anatomy, operative surgery, and clinical practice. One optional subject must also be taken, the range of these specialisms covering nearly every branch of medicine. The fee to be paid on entering for examination for Fellowship is £45, £10 of which is remitted to those who already hold the Licentiateship of the College. Candidates rejected at the examination obtain repayment of fee less £10 retained for examination expenses. One month's notice of intention to present himself for examination must be given by the candidate to Mr. D. L. Eadie, 50, George-square, Edinburgh, clerk to the College, together with credentials signed by two Fellows of the College, one of whom must be a resident in Edinburgh, unless a special application be made to the President and the Council of the College.

THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Like the preceding corporations, the Royal Faculty of Physicians and Surgeons of Glasgow grants a Fellowship and a Licence to be held as separate qualifications.

Fellowship.—The Fellowship of the Faculty is granted after examination in medicine or surgery, together with an optional subject, which may be anatomy or physiology or be selected from any special branch of medicine or surgery, or in one subject to medical practitioners who serve in the present war. 14 days' notice must be given by the candidate of his intention to present himself to Mr. Walter Hurst, the Faculty Hall, 242, St. Vincent-street, Glasgow. The fee for the Fellowship is £30, £10 of which sum are returned to any successful candidate who already holds the Licence of the Faculty. An additional sum of £20 is required in the case of candidates resident within seven miles of Glasgow. In certain circumstances Fellows may be elected as a mark of distinction. Special regulations are in force for medical practitioners serving in the present war.

Licence.—The Licence of the Royal Faculty is granted as a separate qualification to qualified practitioners in Medicine after examination in surgery, including surgical anatomy and clinical surgery. The fee is 15 guineas.

SCOTTISH PROVINCIAL ANCILLARY SCHOOLS AND HOSPITALS.

The hospitals which are recognised by the Scottish Conjoint Board, as places where professional study for their diplomas can be pursued are all those institutions which feed the medical faculties of the universities. In addition the Scottish Boards recognise all the places which are recognised by the English Conjoint Board (see p. 284) and the Irish Conjoint Board (see p. 295).

III.—IRELAND.

THE UNIVERSITIES.

UNIVERSITY OF DUBLIN, TRINITY COLLEGE (SCHOOL OF PHYSIC).

Matriculation.—All students intending to join the School of Physic must pass a matriculation examination. University students take the Entrance of Trinity College and a Junior Freshman Term or a special Medical Preliminary; Extern Students, any examination recognised by the General Medical Council. The winter courses begin on Oct. 1st.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of matriculation. The Arts course may be taken concurrently with the Medical course, and the B.A. degree need not be taken before the final medical examinations, but the Medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Lectures—Systematic, Descriptive and Applied Anatomy, Chemistry and Practical Chemistry, Surgery and Operative Surgery, Histology, Botany, Zoology, Physics and Practical Physics, Physiology and Practical Physiology, Practice of Medicine, Midwifery, Pathology, Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene; (2) three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Hospital; (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months; (5) Practical Midwifery with Clinical Lectures, including not less than 30 cases, six months; (6) Ophthalmic Surgery, three months. Three groups of examinations have to be passed. Preliminary Scientific Examination, including Physics and Chemistry, Botany, and Zoology. The Intermediate Medical, Part I., including Anatomy and Physiology. The Intermediate Medical, Part II., including Applied Anatomy and Applied Physiology; and the Final Examination, which is divided into Part I., Materia Medica, Hygiene and Jurisprudence, and Pathology; and Part II., Medicine, including Clinical, Surgery, Midwifery, Gynæcology, Mental Diseases, Operations, and Clinical Ophthalmology. Part I. may be passed in the fourth year and Part II. completed at the end of the fifth year.

Doctor in Medicine.—A Doctor in Medicine must have passed all the qualifying examinations and must be a B.A. of three years' standing. He must also read a thesis before the Regius Professor of Physic.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study, or study and practice, of his profession. He must then pass a special examination.

Master in Obstetric Science.—A Master in Obstetric Science must be a Bachelor of two years' standing and produce evidence of having been engaged in the study of Obstetric Medicine and Surgery during two years. He is then required to pass a special examination.

A post-graduate diploma in Gynæcology and Obstetrics is conferred upon registered medical practitioners who take a six months' course at the Rotunda Hospital and a six months' course in Trinity College when they have passed a special examination.

University Diplomas.—Candidates for the diplomas in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine and must have completed two years in Arts and five years in Medical Studies. The Course and Examination necessary for the diplomas are the same as for the degrees. A diploma in Medicine, Surgery, and Midwifery is a registrable qualification conferred upon candidates who have completed a full five years' course in Medicine and two years in Arts. A diplomate, on completing his course in Arts and proceeding to the degree of B.A., may become a Bachelor by paying the degree fees.

Bachelor in Dental Science and Master in Dental Science.—The regulations under which these degrees are awarded can be obtained by application to the Registrar of the School of Physic.

All Degrees and Courses of Instruction are open to women students.

Clinical instruction.—The hospital facilities for clinical instruction available in Dublin will be described below.

THE NATIONAL UNIVERSITY OF IRELAND.

Matriculation.—All students intending to proceed to the medical degree of the University of Ireland must pass a matriculation examination, the examination taking place in June and September in Dublin and at certain local centres. All students must pass in five subjects. All students must pass in the following subjects[1] except students not born in Ireland, and other students whose home residence shall have been outside Ireland during the three years immediately preceding their matriculation; but all such students will be expected to attend a course of instruction in Irish Literature and History prior to obtaining any degree in the University:—1. Irish. 2. Latin or Greek. 3. French, German, Italian, Spanish, Portuguese, Welsh, or any other language approved by the Senate. 4. English. 5. Mathematics. 6. Latin, Greek, French, German, Welsh, Spanish, Italian, Portuguese, or any other modern language approved by the Senate, History and Geography (*as a composite subject*), Natural Philosophy, or Physics as an alternative, Chemistry, Botany, and for women candidates only, Physiology, and Hygiene. Candidates who under the regulations are exempted from the necessity of presenting Irish as one of their subjects may present as their fifth subject either a second language or a second science subject. Students entering for degrees in Medicine or Dentistry, if already registered by the General Medical Council, may be accepted as matriculated students of the Faculty of Medicine on passing the matriculation examination in any faculty of the University.

The medical degrees granted are:—

M.B., B.Ch., and B.A.O.; and M.D., M.Ch., and M.A.O.—Printed forms of application for admission to any medical examination may be had from "The Registrar, The National University of Ireland, Dublin."

The Constituent Colleges of the National University of Ireland at which the full curriculum for medical degrees can be obtained are University College, Dublin; University College, Cork; and University College, Galway.

UNIVERSITY COLLEGE, DUBLIN.—The University and the College were created by the Irish University Act, 1908, and by Charters issued in December, 1908. Former students of the Cecilia-street School of Medicine who graduated in the Royal University may become graduate members of the new College. The constitution of the College, like that of the Constituent Colleges of Cork and Galway, provides for a governing body, an academic council consisting of professors and coöpted lecturers, a body of graduate members, and a body of student members matriculated in the University. The first professors and lecturers were appointed by the Dublin Commissioners Irish Universities Act, 1908.

Matriculation.—Almost all the students of the College are matriculated students of the National University of Ireland.

University Examinations in Medicine.—The First Examination includes Physics, Chemistry, Botany, and Zoology. The examination may be taken in two parts: Part I., Physics and Chemistry; Part II., Botany and Zoology. Honours may be obtained only when both parts are taken as one examination. The Second Examination includes Anatomy and Physiology. Both must be passed at the same

[1] The Senate has directed that candidates who presented themselves for the Matriculation Examination and who passed in certain subjects in 1912 or any previous year, may, when presenting themselves in 1919, in the remaining subjects necessary to complete the examination, select such completing subjects in accordance with the regulations as to groups of subjects which were in force in 1912. Such candidates will not be obliged to present themselves for examination in Irish. Such candidates, however, while they may select the completing subjects as above, must present themselves for examination in these subjects on the courses prescribed in each by the Regulations in 1913. Candidates who presented themselves for the Matriculation Examination, and who passed in certain subjects in 1913, when presenting themselves in 1919 in the remaining subjects necessary to complete the examination, must select such completing subjects in accordance with the regulations as to groups of subjects which were in force in 1913. The courses in such completing subjects will be the courses prescribed in those subjects respectively for 1919.

time. The Third Examination includes Pathology, Medical Jurisprudence and Hygiene, and Materia Medica.

Degrees of M.B., B.Ch., and B.A.O.—The Examination in Medicine, Midwifery, Surgery, and Ophthalmology includes both the theoretical and the clinical branches. No student can enter for the M.B., B.Ch., or B.A.O. until the end of the fifth year when the curriculum has been completed. The course of study is as follows:—First year.—Winter: Anatomy and Practical Anatomy (required for the Second Examination),[2] Chemistry, Practical Chemistry, and Experimental Physics (with Laboratory Course). Summer: Zoology, Practical Zoology, Botany, and Practical Botany. Second year.—Winter: Anatomy, Practical Anatomy, Physiology, and Practical Physiology (physical and chemical). Summer: Anatomy, Practical Anatomy, Physiology, and Practical Histology. Third year.—Winter: Pathology, Surgery or Medicine, Hygiene, Medical Jurisprudence, and Practical Pharmacy. Summer: Materia Medica and Therapeutics, and Practical Pathology. Candidates are also required to attend a General Hospital for nine months (winter and summer). Fourth year, or fourth and fifth years.—Winter: Medicine or Surgery (the subject to be that not taken in the third year), and Midwifery and Gynæcology. Summer: Operative Surgery, Applied Anatomy, and Ophthalmology and Otology. Candidates are also required to attend a General Hospital for nine months (winter and summer), and to take instruction in Vaccination, and three months Fever Hospital. Fifth year.—If the Academic (Collegiate) Courses are taken as above, the Courses of the fifth year will be the following: Hospital Attendance, General Hospital, nine months; Clinical Ophthalmology and Otology, three months; Practical Midwifery and Gynæcology, six months; Mental Diseases, to be attended at a Lunatic Asylum, three months. (Note.—Practical Midwifery and Gynæcology may be taken in the fourth year after the Systematic Course of Midwifery, but it must not be taken concurrently with the period of attendance at Fever Hospital.) The degree of M.D. may be obtained either by examination or on published work.

Fees.—The fees for Courses are similar to those of the other Dublin Medical Schools.

Information concerning these, and the numerous scholarships and exhibitions of the College can be obtained from the Dean of the Faculty, Professor E. P. McLoughlin.

UNIVERSITY COLLEGE, CORK: THE SCHOOL OF MEDICINE.—The building is provided with a very large, well-ventilated dissecting room supplied with electric light, with physiological, toxicological, pathological, and pharmaceutical laboratories, materia medica, anatomical and pathological museums, as well as a collection of surgical and obstetrical instruments and appliances. There are well-appointed physical, chemical, and biological laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are well filled with plants and are open to the students in the class of Botany. The Library contains over 50,000 volumes and is open daily during term time to students. The Medical Museum occupies a large room erected at the northern end of the medical buildings. There are Students' Clubs for men and women students of the College and various athletic clubs, the last of these holding a public meeting once in each year in the Mardyke grounds.

All students who have been admitted as matriculated students are required to attend before the President and sign the Roll of Matriculated Students. Students who may be candidates for degrees in the National University of Ireland must have passed the Matriculation Examination of that University or other recognised examination, and medical students must have passed a preliminary examination recognised by the General Medical Council. Candidates will be examined in Irish, Greek, or French or German, Latin, History, Geography, English, and Mathematics.

Admission of Medical Students.—Students in the Faculty of Medicine who have passed the First Professional Examination of the Conjoint Examinations of the Royal College of Physicians and the Royal College of Surgeons in Ireland, or of the Royal College of Physicians and Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, or of the Royal College of Physicians, London, and Royal College of Surgeons, England, may be admitted to the rank of second-year students on making application to the Council and submitting a certificate of having passed the examination. Similarly, students who have passed the Second Professional Examination of the same Colleges may be admitted to the rank of third-year students; and those who have passed the Third Professional Examination of the Dublin Colleges, or of the Edinburgh Colleges and Glasgow Faculties, may be admitted to the rank of fourth-year students.

Residence of Students.—There is no accommodation for the residence of students within the College, but students not living at home, or with relatives or friends, sanctioned by their parents or guardians, are required to live in a hostel or in recognised lodgings, a list of which can be obtained from the Secretary. All students are required to register their addresses each session in the book kept for that purpose in the hall porter's office, and to notify immediately to the Registrar any change of address during the session. The Honan Hostel, adjoining the College, is equipped by private endowment. A number of sets of rooms, together with recreation and common rooms, are provided for lay students who may desire to live there. For full particulars apply to the Warden. The Ursuline Convent, Blackrock, has a house of residence, quite separate from their Secondary School, for Catholic women students.

Clinical Instruction.—Students may attend the South Infirmary, Cork North Charitable Infirmary, the Mercy Hospital, the Cork District Lunatic Asylum, the Victoria Hospital for Diseases of Women and Children, the County Lying-in Hospital, the Cork Maternity, the Cork Fever Hospital, the Cork District Hospital, and the Cork Ear, Eye, and Throat Hospital.

Complete information with regard to class fees, scholarships, and prizes can be obtained from the Dean of the College, Professor A. E. Moore.

South Infirmary and County of Cork General Hospital (100 beds).—Clinical instruction is given daily in the wards. Special instruction on Diseases of Women and Children will be given in the special wards for such cases. Fee for perpetual ticket, £22 1*s.*; for nine months, £9 9*s.*; for six months, £6 6*s.*; for three months, £3 3*s.* Two resident pupils will be appointed by competitive examination. Honorary Secretary: Dr. N. I. Townsend.

Cork North Charitable Infirmary and County and City of Cork General Hospital (112 beds).*—Clinical instruction is given daily in the wards by the physicians and surgeons. Special instruction is given to Junior Students on two days weekly. Fee for perpetual ticket, £22 1*s.*; for 12 or nine months, £9 9*s.*; for six months, £5 5*s.*; and for three months, £3 3*s.* Two resident pupils are appointed quarterly by the medical staff. All resident pupils are required to be registered pupils of the hospital. There is a special department for treatment of the eye, ear, throat, and nose, and a special dental department. Honorary Secretary: Mr. R. B. Dalton.

Mercy Hospital.—This hospital contains 130 beds for medical and surgical cases. There is also a daily extern for medical and surgical cases, as well as for diseases of the eye, ear, and throat. Extern medical attendances, 3371; surgical attendances, 2361; eye, ear, nose, and throat attendances, 7200; intern patients, 1354. Major operations, 254; minor operations, 567. Two resident students. Honorary Secretary to the Staff: Dr. D. J. O'Connor.

Cork District Lunatic Asylum.—Psychological Medicine: A course of Clinical Lectures on Mental Disease and Allied Neuroses will be delivered in the Cork District Lunatic Asylum on Mondays and Thursdays, commencing the first Thursday in May, by the Resident Medical Superintendent. All students wishing to enter for the course are expected to attend at the Asylum at 4 P.M. on that day. All information may be had at the Asylum from the resident medical superintendent.

Victoria Hospital (Incorporated) (Cork).—There are 75 beds. Clinical instruction on Diseases Peculiar to Children is given. The extern department is open daily at 9.30.

County and City of Cork Lying-in Hospital (Erinville, Western-road; founded 1798).—This hospital contains 20 beds, and an Extern Midwifery Department. Fee for six months' attendance, including clinical lectures, £3 3*s.* For further particulars apply to N. H. Hobart, honorary secretary to staff.

---

[2] These courses are not required for the First Examination in Medicine, but must be taken in the first year to permit a candidate to qualify for admission to the Second Examination in Medicine at the end of the second year.

* No returns.

Cork Maternity (Batchelor's Quay).—Three resident pupils are taken into the Maternity. Poor women are attended at their own homes. Clinical lectures are delivered during the session. There is an extern department for the treatment of women's and children's diseases. Fee for attendance at clinical lectures and certificate, £3 3*s*. Honorary secretary to staff, Dr. Henry Corby.

Cork Fever Hospital.—Upwards of 500 cases of various forms of fever and zymotic disease are treated yearly in this hospital. The Resident Medical Officer gives instruction in Practical Pharmacy, a certificate of which is necessary for the National University and Colleges of Physicians and Surgeons of Edinburgh.

Cork District Hospital (Douglas-road; 1200 beds).—This hospital includes special buildings for fever and other infectious diseases (100 beds); for children's diseases (100 beds); and a Lock hospital, the only one in the South of Ireland (80 beds). It affords an extensive field for the study of all classes of diseases, acute and chronic, including special departments for gynæcology and diseases of the skin and nervous system. The physicians and surgeons visit the hospitals every morning at 10 o'clock. Lectures and clinical instruction are given daily in the wards by the physicians and surgeons. Further particulars may be obtained from Dr. W. E. Ashley Cummins, 17, St. Patrick's-place, honorary secretary, medical staff.

Cork Eye, Ear, and Throat Hospital (Western-road).—This hospital is open to students attending the University College and others. Certificates of attendance for three or six months can be obtained. The hospital contains 35 beds. Over 4000 cases are treated during the year. A course of Lectures on Ophthalmic Surgery is delivered during the session. For further information apply to Dr. Arthur Sandford, 13, St. Patrick's-place, Cork.

UNIVERSITY COLLEGE, GALWAY: SCHOOL OF MEDICINE.—The College contains well-lighted and ventilated dissecting-room and anatomical lecture theatre; physiological, pathological, pharmaceutical, chemical, and physical laboratories; anatomical, pathological, gynæcological, and materia medica museums; as well as a large natural history and geological museum and an extensive library in which students can read and from which they can borrow books. There are 12 Entrance Scholarships, value £25 each, for which Medical Students compete with other Students on the Entrance Course. In the Second, Third, and Fourth Years two Scholarships in each year, value £25 each, are reserved for Medical Students. Exhibitions of £10 and £5 are awarded on results of 1st, 2nd, 3rd, and Degree Examinations in Medicine. H. H. Stewart Scholarships (£10 a year for three years) are awarded by the University in Anatomy and Physiology at Second Medical Examination amongst Students of the three constituent Colleges. Travelling Studentships (£200 a year for two years) are offered by the University for competition amongst Medical Graduates of the three Colleges of not more than two years' standing. Women students are eligible for all College and University Degrees, Distinctions, and Prizes. There are extensive grounds, a portion of which is occupied by a Botanic Garden and a portion is at the disposal of the College Athletic Union. There are several student societies in the College, including a Biological Society. There are abundant facilities for research and Post-graduate work in the Chemistry, Physiology, and Pathology departments. There are ample facilities for Women Students. Further information can be obtained from the Registrar of the College.

Clinical Instruction is given in the Galway Hospital and in the Galway Union and Fever Hospitals, containing on an average 200 patients.

Galway County Hospital (62 beds).—Founded by Act of Parliament.

Galway Union and Fever Hospitals (150 beds).—Clinical instruction is given in these hospitals to the Medical Students of University College, Galway. The regulations for Scholarships tenable in the College, and the regulations for degrees and for courses can be obtained from Messrs. O'Gorman and Co., Galway.

QUEEN'S UNIVERSITY OF BELFAST.

There are six degrees in the Faculty of Medicine of the University—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), and Master of Obstetrics (M.A.O.). The University also grants a Diploma in Public Health, particulars of which will be found in the University Calendar. The degrees of M.B., B.Ch., and B.A.O. are the primary degrees in the Faculty of Medicine, and are conferred at the same time and after the same course of study. No student is admitted to the final examination for these degrees until he has shown: (1) that he is a matriculated student of the University; (2) that he has completed the prescribed course of study in the Faculty of Medicine extending over a period of not less than five academic years from the date of his registration as a student of Medicine by the General Council of Medical Education and Registration of the United Kingdom; (3) that he has passed the several examinations prescribed; (4) that he has attended in the University during three academic years at least the courses of study prescribed for such degrees (the Senate may accept, for not more than two academic years of the required five, courses of study pursued in any other University or School of Medicine approved by the Senate); and (5) that he has attained the age of 21 years. Every candidate for admission as a matriculated student of the University shall pass such Matriculation Examination or fulfil such other test of fitness as may be prescribed by the Senate, which may prescribe the conditions under which students who have passed the Matriculation or Entrance Examination of any other University or College approved for that purpose (or who have fulfilled such other test of fitness as may be prescribed) may be exempted from passing the Matriculation Examination of the University. For information as to Scholarships and Prizes inquiry should be made of the Secretary of the University.

Primary Degrees of M.B., B.Ch., B.A.O.—All candidates for these degrees must satisfy the examiners in the subjects of four examinations known as the First, Second, Third, and Fourth Medical Examinations respectively.

The First Medical Examination.—The subjects of this examination are Chemistry (Inorganic and Organic), Experimental Physics, Botany and Zoology. The examination will be divided into two parts which may be taken separately: I., Chemistry and Physics; II., Botany and Zoology.

The Second Medical Examination.—The subjects are Anatomy and Practical Anatomy, Physiology and Practical Physiology. Candidates who have previously passed the First Medical Examination may present themselves for this examination at the close of their second year.

The Third Medical Examination.—The subjects are: (1) Pathology and Practical Pathology; (2) Materia Medica, Pharmacology and Therapeutics; (3) Medical Jurisprudence; (4) Hygiene. Candidates who have previously passed the Second Medical Examination may present themselves for this examination at the close of the third year. Attendance on a course in any subject of the Third Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the First Medical Examination.

The Fourth Medical Examination.—The subjects are: (1) Medicine; (2) Surgery; (3) Midwifery; (4) Ophthalmology and Otology. This examination may be taken in two parts: I., Systematic; II., Clinical, Practical and Oral. Candidates who have previously passed the Third Examination may present themselves for Part I. of the Fourth Examination at the close of the fourth year, provided that they have fulfilled the necessary requirements as to attendance, &c., on the courses of instruction in the subjects of examination. Candidates who have passed Part I. of this examination may present themselves for Part II. at the close of the fifth year, provided that they have fulfilled the necessary requirements as to hospital attendance on the various clinical courses in the subjects of examination. Parts I. and II. may be taken together at the close of the fifth year. Attendance on a course in any subject of the Fourth Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the Second Medical Examination.

Degrees of M.D., M.Ch., and M.A.O.—These degrees are not conferred until the expiration of at least three academic years, or in the case of graduates of the University in Arts or Science of at least two academic years, after admission to the primary degrees in the Faculty of Medicine. Every candidate must show that in

the interval he has pursued such courses of study, or been engaged in such practical work as may be prescribed. These degrees may be conferred by the Senate either (*a*) after an examination, which includes written, oral, clinical, and practical examinations; or (*b*) on the submission of a thesis or other evidence of original study or research, to be approved by the Faculty of Medicine after an oral or other examination of the candidate on the subject thereof.

The Medical School.—The Donald Currie Chemical Buildings contain a lecture theatre, a preparation room, a chemical museum, a large class-room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes and balance room, provided with all modern appliances. The Anatomical Department contains a large and well-lighted dissecting-room, a lecture-room, a professor's and demonstrator's room, a bone-room, and a laboratory for microscopic and photographic work. The Medical Museum is in the same building. The Jaffé Laboratories for Physiology comprise a lecture theatre, laboratories for practical work in chemical physiology, histology, and experimental physiology, and in addition small private research rooms, including balance, galvanometer, and centrifuge rooms. The Musgrave Pathological Laboratory.—In this department opportunity is afforded for research in pathology and bacteriology. The department is in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases. A course in pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, the diagnosis of cases of infectious diseases, &c. The certificate issued to members of the class in bacteriology qualifies for the D.P.H. degree. The Pharmaceutical Laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines.

Clinical instruction.—The following institutions are recognised by the University as affording proper opportunities for clinical instruction: the Royal Victoria Hospital, the Mater Infirmorum Hospital, the Union Hospitals, the Belfast Hospital for Sick Children, the Belfast Maternity, the Ulster Hospital for Women and Children, the Ulster Eye, Ear, and Throat Hospital, the Belfast Ophthalmic Hospital, the Purdysburn Fever Hospital, and the Belfast District Lunatic Asylum.

The Royal Victoria Hospital (300 beds).—Many of the staff are on active service. Women students are now admitted as resident medical pupils the same as men.

Mater Infirmorum Hospital (200 beds).—Honorary Secretary Medical Staff: Mr. J. B. Moore.

Belfast Union Infirmary and Hospital (1700 beds).—Four Resident Medical Officers.

Hospital for Sick Children, Queen-street (52 beds).—Honorary Secretary, Medical Staff: John McCaw, M.D.

Maternity Hospital, Townsend-street (32 beds).

Ulster Hospital for Children and Women (44 beds).

Benn Ulster Eye, Ear, and Throat Hospital (30 beds).

Belfast Ophthalmic Hospital, Great Victoria-street (30 beds).—Practical demonstrations by the staff and occasional clinical lectures in the subjects of Ophthalmology, Otology, Laryngology, and Neurology. Clinical instruction is given daily. Fee for three months £2 2*s*.

City Fever Hospitals, Purdysburn (330 beds).—Clinical Classes are held during the winter and summer sessions.

Belfast District Lunatic Asylum (1250 beds).

IRISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

The College issues its Licences in Medicine and in Midwifery to practitioners whose names appear on the Medical Register of the United Kingdom.

The Licence in Medicine.—The subjects of examination are: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

The Licence in Midwifery.—Candidates must produce certificates of registration. A registered medical practitioner of five years' standing may be exempted from the examination by printed questions.

The Membership.—Examinations for Membership are held in February, June, and November. The fee for the examination is £21 to Licentiates of the College, or £36 15*s*. to non-Licentiates. Further particulars can be obtained from the Registrar of the Royal College of Physicians of Ireland, Kildare-street, Dublin.

The Fellowship.—Fellows are elected by ballot. Applicants must have been a Member of the College for at least one year and must have attained the age of 27 years. There is a fee of £35 in addition to a stamp duty of £25.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Licence in Surgery.—A candidate whose name is entered either on the Medical Register for the United Kingdom, the Colonial Medical Register, or the Foreign Medical Register of the year in which he presents himself for examination, and who satisfies the Council that he has passed through a course of study and Examinations equivalent to those required by the Regulations of the Conjoint Board of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland, preceded by the passing of an Examination in Arts recognised by the General Medical Council, may, at the discretion of the Council, be admitted to the Examination.

Candidates are examined in Surgery, Clinical Surgery, Operative Surgery on the subject, Surgical Appliances, and Ophthalmic Surgery.

Diploma in Midwifery.—A diploma in Midwifery is granted after examination to persons possessing a registrable qualification.

Fellowship Examinations.—Candidates for the Fellowship shall make application to the President and Council to be admitted to examination. They are required to pass two examinations—Primary and Final. Candidates may present themselves for the Final Examination immediately after passing the Primary part, provided they have complied with the necessary regulations. The subjects for the Primary Examination are (*a*) Anatomy, including Dissections; and (*b*) Physiology and Histology. The subjects for the Final Examination are Surgery, including Surgical Anatomy and Pathology. For admission to the Final Examination the candidate must have passed the Primary Examination, and must be a Licentiate or Graduate in Surgery of a university or licensing body recognised by the General Medical Council; all such candidates must not be less than 25 years of age.

Further particulars as to fees and conditions of examination can be obtained from the Registrar of the College, Stephen's-green, West Dublin.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND ROYAL COLLEGE OF SURGEONS IN IRELAND.

Every candidate for the Conjoint Examinations of the Colleges shall produce evidence of having before entering on medical studies passed a Preliminary Examination in general education recognised by the Royal Colleges. Each candidate before receiving his diplomas must produce a registrar's certificate or other satisfactory evidence that he has attained the age of 21 years.

Preliminary Examination.—The subjects for examination are identical with those prescribed for the Preliminary Examination by the General Council of Medical Education and Registration.

Professional Examinations.—Every candidate must pass four Professional Examinations—at the end of the first, second, third, and fifth years respectively of his professional studies. No candidate shall be admitted to the Final or Qualifying Examination within three months of his rejection at the Final or Qualifying Examination by any other licensing body.

First Professional Examination.—Every candidate is required, before admission to the First Professional Examination, to produce evidence—(1) of having passed in the subjects of the Preliminary Examination; and (2) of having attended a course of—(*a*) lectures on Theoretical Chemistry, six months; (*b*) Practical Chemistry, three months; (*c*) Biology, three months; and (*d*) Physics.

The subjects of the First Professional Examination are the following:—1. (*a*) Chemistry; (*b*) Physics. 2. Biology. The fee for this examination is £15 15*s*.

Second Professional Examination.—Candidates are not admissible to this examination till they have passed in the subjects of the First Professional Examination, and they must produce evidence of having attended (*a*) anatomical dissections, six months; and Lectures on (*b*) Anatomy, six months; (*c*) Physiology, six months; (*d*) Practical Physiology and Histology, three months.

The subjects of the Second Professional Examination are the following:—(1) Anatomy; and (2) Physiology and Histology. The fee for this examination is £10 10*s*.

Third Professional Examination.—Every candidate is required, before admission to the Third Professional Examination, to produce evidence of having passed the Second Professional Examination, and certificates of having attended courses of instruction in (*a*) the practice of a medico-chirurgical hospital for nine months; (*b*) Pathology—(1) Systematic, (2) Practical, three months each; (*c*) Materia Medica, Pharmacy, and Therapeutics, three months; (*d*) Forensic Medicine and Public Health, three months. The subjects for the Third Professional Examination are the following:—(1) Pathology; (2) Materia Medica, Pharmacy, and Therapeutics; (3) Public Health and Forensic Medicine. The fee for this examination is £9 9*s*.

Final Professional Examination.—Before admission to the Final Examination candidates must have passed the Third Professional Examination and produced evidence of having attended in Division I. the practice of a medico-chirurgical hospital for two periods of nine months each (unless such evidence has been previously produced for admission in Division II.); the practice of a recognised fever hospital or the fever wards of a recognised clinical hospital, three months; clinical instruction in Mental Diseases, one month (12 attendances); lectures on Medicine, six months at a recognised medical school; of having performed the duties of medical clinical clerk in a recognised hospital for three months; of having attended a course of instruction in post-mortem examinations and demonstrations during one session. In Division II. of having attended the practice of a medico-chirurgical hospital for two periods of nine months each (unless such evidence has been previously produced for admission to Division I.); clinical instruction in Ophthalmic and Aural Surgery, three months; lectures on Surgery, six months at a recognised medical school; instruction in Operative Surgery, three months at a recognised medical school; of having performed the duties of surgical dresser in a recognised hospital for three months; of having attended a course of instruction in the practical administration of general anæsthetics. In Division III. of having attended a midwifery hospital or maternity and having been present at 20 labours, six months; instruction on vaccination, six attendances to be certified by a public vaccinator; lectures on midwifery (including diseases peculiar to women and to new-born children), six months at a recognised medical school. Candidates are recommended to present themselves in all the subjects of the Final Examination at one time, but a candidate at or after the end of the fourth year may present himself in any one of the Divisions I., II., or III., provided he has completed his curriculum as far as concerns the division in which he presents himself. The examination in at least one of the divisions must be deferred till the end of the fifth year.

The subjects of the Final Examination are: (1) Medicine, including Fevers, Mental Diseases, and Diseases of Children; (2) Surgery, Operative and Ophthalmic; and (3) Midwifery and Gynæcology, Vaccination, and Diseases of New-born Children. The fee is £6 6*s*. Further particulars can be obtained from Alfred Miller, the Secretary of the Committee of Management, Royal College of Surgeons, Stephen's-green, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND (SCHOOLS OF SURGERY).—The schools of surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for over a century. They are carried on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction. There are special rooms set apart for lady students. The entire building is heated by hot-water pipes and lighted throughout by the electric light. Winter Session commences in October; Summer Session in April. Scholarships and Prizes: Carmichael Scholarship, £15; Mayne Scholarship, £8; Stoney Memorial gold medal; Operative Surgery, gold and silver medals; Barker Prize, £26 5*s*.; H. Macnaughton-Jones gold medal; and class prizes and medals. Prospectuses and guide for medical students can be obtained post free on written application to the Registrar, Royal College of Surgeons, Stephen's-green, W., Dublin.

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum and who pass the necessary examinations. The diploma of the Apothecaries' Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, with also the privileges of the Apothecary's Licence. There are three professional examinations, the total fees for which amount to 30 guineas. Women are eligible for the diploma.

There are four examinations—primary, intermediate, Parts I. and II., and final. They are held three times a year, in March, June, and December. The primary examination comprises biology, physics, theoretical and practical chemistry (with an examination at the bench). Candidates holding a Pharmaceutical licence are exempt from this subject. Intermediate, Part I., Anatomy and Physiology. Intermediate, Part II., Pathology, Medical Jurisprudence, and Materia Medica and Pharmacy. The intermediate examination comprises anatomy of the whole body (including practical dissections), physiology, practical histology, and materia medica. The final examination comprises medicine, surgery, and midwifery.

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21 years. The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar at 40, Mary-street, Dublin.

HOSPITALS AFFORDING PRACTICE RECOGNISED BY THE IRISH UNIVERSITIES AND CORPORATIONS.[1]

ADELAIDE HOSPITAL, Peter-street, Dublin.—Fee for nine months' hospital attendance, £12 12*s*.; six months, £8 8*s*. Summer, three months, £5 5*s*. Two resident surgeons are elected yearly and four resident pupils half-yearly. At the termination of the session prizes in Clinical Medicine and Surgery and in Dermatology will be awarded.

Hudson Scholarship.—In addition to the junior prizes the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in medicine, surgery, gynæcology, and pathology.

The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. Further particulars may be obtained from Dr. H. Bewley.

COOMBE LYING-IN HOSPITAL AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN, Dublin.—This hospital contains nearly 70 beds and consists of two divisions, one of which is devoted to lying-in cases and the other to the treatment of diseases peculiar to women. The practice of this hospital is one of the largest in Ireland. Lectures are delivered, practical instruction given, and gynæcological operations are performed in the theatres daily. There is a general dispensary held daily, at which instruction is given on the Diseases of Women and Children. There is a special afternoon dispensary held by the Master and his assistants, at which practical instruction in gynæcology is given. There is no extra charge for attendance at this dispensary. There is accommodation for intern pupils who enjoy exceptional advantages

[1] This list of the institutions recognised by the Conjoint Board of Ireland is supplemented in the regulations of the Colleges by those hospitals mentioned as recognised institutions in Scotland and England. The recognised facilities for clinical instruction in Belfast, Cork, and Galway have been described in connexion with the Belfast and National Universities.

of acquiring a thorough knowledge of this branch of their profession. Lady medical students can reside in the hospital. The residents' quarters are comfortable. Clinical assistants are appointed from amongst the pupils as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies. Fees: Extern pupils for full course of six months, £8 8*s.*; three months, £4 4*s.* Intern pupils, one month, £4 4*s.*; each consecutive month, £3 3*s.*; six months, £18 18*s.*; board and lodging in the hospital, 25*s.* per week. Lady students, intern, one month, £4 4*s.*; each consecutive month, £3 3*s.* Registration fee, in advance, 10*s.* 6*d.* Students can enter for attendance at any time, but preference is given to those entering from the first day of the month. Further particulars may be had on application to the Master or the Registrar at the hospital.

SIR PATRICK DUN'S HOSPITAL, Grand Canal-street, Dublin.—Classes both in Medicine and Surgery are held each morning from 9 o'clock from Oct. 1st till the end of June. Special classes for junior students will be held in the wards during the months of October, November, and December. A Resident Surgeon, with salary, is appointed annually. Six Resident Pupils are appointed each half-year. Six Surgical Dressers and six Clinical Clerks are appointed each month. There are facilities for women students.

Prizes and Medals.—Clinical medals and prizes amounting to about £15 each will be awarded in Medicine and in Surgery respectively in accordance with the will of the late Rev. Samuel Haughton, M.D., S.F.T.C.D. Candidates who fail to obtain these medals and prizes will be awarded special certificates in Medicine and in Surgery provided they show sufficient merit.

Fees.—Winter and summer session, £12 12*s.*; winter session (six months), £8 8*s.*; and summer session (three months), £5 5*s.* Special certificate in anæsthetics, £1 1*s.* The practice of this hospital is open to all students, and the certificates are recognised by Dublin University, the National University and Royal Colleges of Surgeons of England, Ireland, and Scotland.

Further information will be supplied by the Hon. Secretary to the Medical Board, Dr. C. M. Benson.

JERVIS-STREET HOSPITAL, Dublin.—Founded 1718; rebuilt 1886. 130 beds. A new out-patient department has been completed and contains all modern requirements. Secretary: Mr. Kieran O'Dea.

MATER MISERICORDIÆ HOSPITAL, Dublin.—This hospital, the largest in Ireland, containing 345 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction will be given by the Physicians and Surgeons at 9 A.M. daily. Ophthalmic Surgery will be taught in the Special Wards and in the Dispensary. Surgical Operations will be performed daily. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, and Accidents. Instruction will be given on Pathology and Bacteriology. Three House Physicians, six House Surgeons, and 16 resident pupils will be elected annually. Dressers and Clinical Clerks will also be appointed, and certificates will be given to those who perform their duties to the satisfaction of the staff. Leonard Prizes will be offered for competition annually. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom. A Private Hospital has been opened for the reception of Medical and Surgical cases. A Training School and a Home for Trained Nurses have been opened in connexion with the Hospital.

Terms of attendance.—Nine months, £12 12*s.*; six winter months, £8 8*s.*; three summer months, £5 5*s.* Entries can be made with any of the physicians or surgeons, or with the Registrar, Dr. Martin Dempsey, 35, Merrion-square. A prospectus containing in detail the arrangements for Clinical Instruction, Prizes, &c., may be obtained from the Secretary, Medical Board, Mr. A. Blayney, 15, Merrion-square.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.—This hospital was founded in 1753 and now contains 166 beds available for clinical teaching. A building containing 40 beds for the isolated treatment of fevers is attached to the hospital. The certificates of this hospital are recognised by all the universities and licensing bodies of the United Kingdom. Six Medical Clinical Clerks and 12 Surgical Resident Pupils and Dressers are appointed every six months, and House Surgeons and Clinical Assistants are elected annually. A prospectus giving the complete arrangements for the coming session may be obtained from the Honorary Treasurer of the Medical Board, Sir L. H. Ormsby, 92, Merrion-square, Dublin.

MERCER'S HOSPITAL.—This hospital, founded in 1734, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and within five minutes' walk of Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork-street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the posts of Resident Pupil, &c. There is a large dispensary for out-patients. Students of the hospital are permitted to attend the gynæcological department, where they receive practical instruction. There are special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements.

Appointments.—A House Surgeon is appointed annually. There are Five Resident Pupils, and Clinical Clerks and Dressers are appointed monthly from amongst the most deserving members of the class. Women students are admitted.

Fees.—Winter, six months, £8 8*s.*; Summer, three months, £5 5*s.*; nine months, £12 12*s.*

For further particulars apply to Dr. Bethel Solomons, Hon. Sec., Medical Board, 42, Fitzwilliam-square, Dublin.

NATIONAL MATERNITY HOSPITAL, Holles-street, Dublin.—Established 1894. Masters: Sir Andrew J. Horne and Dr. R. J. White. The Hospital consists of an Intern and Extern Maternity. 1000 cases are annually admitted. The large number of cases at the hospital give great opportunities for practical work. Arrangements are made for post-graduate and special courses. Certificates of attendance at the hospital are recognised by all the licensing bodies. For further particulars apply to the Masters.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS, North Brunswick-street, Dublin.—These hospitals contain 317 beds—130 for Surgical cases, 70 for Medical cases, 77 for Fever and other Epidemic Diseases, and an Auxiliary Wing of 40 beds for sick soldiers. A Resident Physician and a Resident Surgeon are appointed each half year and are paid for their services. 12 Resident Clinical Clerks are appointed each quarter and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced Students but also to those who are qualified in Medicine and Surgery. The Dressers are selected from among the best qualified of the pupils without the payment of any additional fee. Women students are eligible for election as residents and special apartments are reserved for their use. For prospectuses apply to Mr. Adams McConnell, F.R.C.S.I., Hon. Secretary, 69, Fitzwilliam-square, Dublin.

ROTUNDA HOSPITAL, Dublin.—This institution is the largest combined gynæcological and maternity hospital in the British Empire. Nearly 4000 confinements attended annually. Students can take out their necessary gynæcological and midwifery practical courses. Appointments open to qualified practitioners as Assistant to the Master and Extern Assistants. Women students can reside in the hospital on terms similar to those for men. For further particulars apply to the Master.

ROYAL CITY OF DUBLIN HOSPITAL.—Founded 1832; enlarged 1851; rebuilt 1893. 150 beds. Secretary: Mr. Edw. B. Armstrong.

ROYAL VICTORIA EYE AND EAR HOSPITAL, Dublin.—Established 1844. Incorporated 1897. 102 beds. In-patients, 1527; out-patients, 9236. Two house surgeons appointed annually.

DR. STEEVENS' HOSPITAL, Dublin.—Established 1720. 250 beds. Patients, 1581. Secretary: Mr. R. J. Ogden.

ST. VINCENT'S HOSPITAL AND DISPENSARY, Dublin.—Established 1834. 160 beds.

WE have received from the Deans and Secretaries of the various centres the corrected lists of the teachers at the schools and of the medical staffs of the hospitals at which clinical education is being carried on. We take the opportunity of thanking these officers for their valuable coöperation, as it enables us to keep the lists revised for reference and future issue.

THE COLONIAL MEDICAL SERVICE.

IN the self-governing dominions, Canada, Australia, New Zealand, the Union of South Africa, and Newfoundland, medical appointments are made concerning which information can be obtained from the High Commissioners or Agents-General in London; appointments in Egypt and the Soudan are regulated from the Foreign Office; in Aden and adjacent territories the appointments are under the control of the Government of Bombay; in Rhodesia the appointments are made by the British South Africa Company, London Wall Buildings, E.C.; in North Borneo application should be made to the British North Borneo Company, 37, Threadneedle-street, E.C., for appointments; and those in Sarawak are in the hands of H.H. the Rajah.

But in addition to all these there are a large number of important posts under the patronage of the Secretary of State for the Colonies. These concern East Africa (the East Africa, Uganda, Nyasaland, Somaliland, and Zanzibar Protectorates); Eastern (Ceylon, the Straits Settlements, and Federated Malay States, Hong-Kong, Weihaiwei, Mauritius, and Seychelles); West India (British Guiana, Jamaica, Trinidad, the Windward Islands, the Leeward Islands, Barbados, British Honduras, and the Bahamas); Fiji and the Western Pacific, Cyprus, Malta, Gibraltar, St. Helena, Bermuda, and the Falkland Islands; and West Africa (Nigeria, the Gold Coast, Sierra Leone, and the Gambia). As a general rule, each Colony or Protectorate has its own public service distinct from that of every other, and it is usually only the higher officers who are transferred by the Secretary of State from one Colony to another; but there are two exceptions to this rule. The West African Medical Staff, which serves Nigeria, the Gold Coast, Sierra Leone, and the Gambia, form one service, and in practice the medical services of the Straits Settlements and the Federated Malay States may be regarded as one, as the officers may be and frequently are transferred from the Colony to the States, or *vice versa*. In Ceylon, Mauritius, Jamaica, Barbados, the Bahamas, and Bermuda vacancies are almost always filled locally by the appointment of qualified native candidates, or—in the case of some of the higher posts—by transfer from other Colonies. Appointments in Malta are all filled locally. Vacancies in the Hong-Kong Medical Department are generally filled by transfer from other Colonies. In most cases the duties of a colonial medical officer are of a very general character, including medical, surgical, and often public health work. It is only occasionally that a specialist is required. All applicants must be between the ages of 23 and 35, but in the case of East Africa, Uganda, Nyasaland, Somaliland, and Zanzibar preference will be given to candidates who are over 25 years of age, while in the case of Fiji and the Western Pacific preference will be given to candidates who are under 30. Candidates must be doubly qualified, and the choice will usually fall, other things being equal, on those who have held hospital appointments. Before being definitely appointed candidates will be medically examined by one of the consulting physicians of the Colonial Office: Sir J. Rose Bradford, K.C.M.G., 8, Manchester-square, London, W.; Sir J. Hawtrey Benson, 57, Fitzwilliam-square, Dublin; Lieutenant-Colonel J. Arnott, I.M.S., 8, Rothesay-place, Edinburgh; and W. T. Prout, Esq., C.M.G., 14, Rodney-street, Liverpool.

East African Protectorates.—Medical Officers in the East Africa, Uganda, Nyasaland, Somaliland, and Zanzibar Protectorates are appointed on probation in the first instance for three years, at the end of which period their appointments are made permanent if their service has been satisfactory, but special arrangements are now in force in Uganda. The salary of a Medical Officer during probation is £400 per annum fixed, but as soon as he has been confirmed in the permanent appointment his salary rises by annual increments of £20 to £500 per annum. There are 17 appointments of this nature in the East Africa Protectorate, 18 in Uganda, 11 in Nyasaland, 5 in Zanzibar, and 3 in Somaliland. In the East Africa Protectorate there are certain special appointments—viz., Deputy Principal Medical Officer (£600–25–700 and £60 duty allowance), Bacteriologist (£600–25–700), Assistant Pathologist and Assistant Bacteriologist (£400), two Senior Medical Officers (£500–25–600 with £50 duty allowance), Analyst (£400–20–450), Chief Sanitation Officer (£600–25–700 and £60 duty allowance), and three Medical Officers of Health (one at £500–25–600 with £50 duty allowance, and two at £400–20–500 with £40 duty allowance). In Uganda there is a Deputy Principal Medical Officer (£500–25–600 and £50 duty allowance), a Bacteriologist (£500 and £50 duty allowance), a Sanitary Officer (£500–25–600 and £50 duty allowance), two Senior Medical Officers with the same emoluments, and a Medical Officer of Health (£400–25–500 and £40 duty allowance). In Zanzibar there is a Medical Officer of Health (£500–25–600, duty allowance £50) and an Assistant (£400–20–500). The salary attached to the appointment of Principal Medical Officer in the East Africa Protectorate is £700 per annum rising to £900 per annum by annual increments of £25, and duty allowance £70. In Uganda the salary of the Principal Medical Officer is £700 per annum, rising to £800 per annum by annual increments of £25, with duty allowance £70; and in Nyasaland and Zanzibar £600 per annum, rising to £700 by annual increments of £25. Medical Officers are permitted to take private practice on the understanding that they give precedence to their official duties. There are also at present in Uganda certain temporary Medical Officers whose appointments (at a salary of £400 a year) have been created in order to cope with the work in connexion with special measures to control sleeping sickness, venereal disease, and plague. A candidate for the Uganda service will in general be offered one of these temporary appointments in the first instance and will be considered for absorption, if he wishes, when an opportunity occurs, provided that his service is approved. Temporary Medical Officers are engaged for three years, and free passages are provided. If a temporary Medical Officer is subsequently appointed to the permanent staff of the Protectorate in which he has been employed on a temporary footing his temporary service will ultimately be reckoned for pension.

Straits Settlements.[1]—Medical Officers are appointed as House Surgeons or Assistant Health Officers at a salary of £350. After one year's satisfactory service House Surgeons are appointed Medical Officers with salary rising from £400 to £600. Above this class there are nine senior appointments carrying salaries ranging from £600 (rising to £720) to £750 (rising to £900). The Principal Civil Medical Officer receives £1050, rising to £1200. Duty allowances are attached to all appointments and free quarters, or an additional allowance in lieu thereof, are given to House Surgeons. The authorised establishment is at present 32 officers.

Federated Malay States.[1]—Appointments are graded as follows:—Principal Medical Officer, £1050 to £1200; Senior Medical Officer, Perak, £750, rising to £900; Senior Medical Officer, Selangor, £800, rising to £1000; seven Medical Officers, Grade I., £600, by £20 annually to £720; 18 Medical Officers, Grade II., £350, and after one year's satisfactory service £400, rising to £600, with free furnished quarters, without private practice. A Medical Officer is attached to the Regiment of Malay States Guides, his salary being £360 to £480. The Senior Medical Officers in Perak and Selangor and the two Grade I. Medical Officers in charge of Negri Sembilan and Pahang are allowed consulting practice only. Other Medical Officers are prohibited from private practice except in very special cases where the Chief Secretary is satisfied that, owing to the absence of private practitioners, it is absolutely necessary to allow the Government Medical Officer to attend to private patients. The posts of Medical Officer, Grade II., in the Federated Malay States and the corresponding appointments in the Straits Settlements are filled by the promotion of officers who have entered the service as House Surgeons. A non-pensionable allowance, varying with the appointment, is attached to all medical posts in the Straits Settlements and Federated Malay States. In the case of House Surgeons the allowance is at the rate of £40 a year.

Seychelles.—There are four medical appointments. The Government Medical Officer receives Rs.4500. The Assistant Government Medical Officers receive Rs.3000. The holders of these latter appointments have free quarters. Private practice is allowed.

Weihaiwei.—There are two non-pensionable Medical Officers on £300, rising to £400, with free quarters.

British Guiana.—There are 35 appointments. Candidates must have held for at least six months a resident medical appointment in some public institution. Officers are appointed on two years' probation as assistant medical officers, and are paid a salary at the rate of £300 per annum, with quarters, without the right to private practice. The permanent staff, to which officers may be appointed at the expiration of the probationary period, includes the following appointments: Surgeon-General, £900, with travelling expenses and consulting practice; Bacteriologist and Pathologist, £300 to £600; two Medical Officers at £600 to £700; 12 Medical Officers at £500 to £600 and 12 Medical Officers at £400 to £500; and five Medical Officers at £300 to £400; two at £300. Officers, on the completion of two years' service in the fixed £300 class, automatically rise to the £300–£400 class. Medical officers appointed to districts receive travelling allowances varying with the nature of the district. They are also allowed private practice. Medical Officers attached to public institutions are, in general, allowed free quarters. A deduction of 4 per cent. is made from their salaries for the payment of the premiums on an insurance of the officer's life for the benefit of the widow or orphans.

Trinidad and Tobago.—In Trinidad and Tobago there are over 40 appointments. Officers are appointed in the first instance on two years' probation as supernumeraries and are eligible for appointment as Government Medical Officers at the end of this period. Applicants must be unmarried and must remain unmarried whilst supernumerary Medical Officers. Supernumeraries receive a salary of £250 per annum with furnished quarters, and are usually attached to the Government hospital. Government Medical Officers receive salary at the rate of £250 per annum with quinquennial increments of £50 accruing from the date of first appointment as supernumerary Medical Officers. Most are employed as District Medical Officers, with private practice, a residence or a rent allowance of £50, a horse allowance, except in one district, and in some cases other allowances for institution work. All officers are required to contribute 4 per cent. of their salaries towards the pensions of the widows and orphans of public officers.

Windward Islands (Grenada, St. Lucia, St. Vincent).—The 25 appointments are, with few exceptions, district appointments with the right to private practice attached; the salaries paid by Government vary from £250 to £350, with allowances in certain cases. The Governor has the power to transfer a medical officer from one island to another at his discretion. The appointments are pensionable.

Leeward Islands (Antigua, St. Christopher and Nevis, Dominica, Montserrat, Virgin Islands).—The 24 appointments are of the same nature as in the Windward Islands, but are not pensionable. An officer when first sent out is not appointed to a particular island but to the service of the Leeward Islands, with a salary of £250, and the Governor decides as to the district which is to be allotted to him. In

[1] In the Straits Settlements and Federated Malay States all permanent Government servants are required to contribute 4 per cent. of their salaries towards the provision of pensions for the widows and orphans of public officers.

certain districts he may be required to perform magisterial duties. The medical officers receive fees for successful vaccinations, post-mortem examinations, attendance and giving evidence at courts of justice, certificates of lunacy, and, in the larger islands, for burial certificates. They are also, as a rule, allowed private practice.

British Honduras.—There are seven medical appointments (besides the principal post of Colonial Surgeon) each carrying a salary of $1701 per annum. Unless they already possess a Diploma of Public Health, medical officers are liable to be required before they join the colony to undergo a course of instruction at a laboratory of public health or analogous institution. The dollar = about 4s. 2d.

Fiji and the Western Pacific.—In Fiji the Government Medical Officers receive a salary of £350, rising by annual increments of £25 to £500, with partly furnished quarters, or a house allowance of £50. In some districts a medical officer is also a magistrate with a combined salary of £500, rising to £600, with free quarters. They are allowed private practice, so far as is consistent with the proper discharge of their duty to the Government, but in most districts the private practice is very small. They are required either to take charge of hospitals or of districts, at the discretion of the authorities. The posts are pensionable. There are at present 15 Medical Officers, in addition to a Chief Medical Officer (£700 a year, rising to £800). The medical services of Fiji and the Western Pacific are interchangeable. While serving in the Western Pacific Protectorates their duties may be of a quasi-magisterial nature, and they draw an extra non-pensionable allowance of £50 per annum.

Cyprus.—There is a Chief Medical Officer paid at the rate of £500 per annum, and three District Medical Officers paid at the rate of £275 per annum, all enjoying private practice (except the Chief Medical Officer, who is allowed consulting practice only) and receiving 2*s.* per diem forage allowance; these are the only medical appointments in the island which are open to English candidates.

Gibraltar.—There is a surgeon of the Colonial Hospital receiving £400 with fuel and light allowances, and private practice. He also receives £50 for medical examination of school children. There are also two Assistant Surgeons with a salary of £350 per annum, who are allowed private consulting practice only. Free quarters, unfurnished, are provided for all three officers.

St. Helena.—The Colonial Surgeon at present receives £270 per annum £20 fees as Health Officer, and £27 horse allowance. Private practice is allowed. The Assistant Colonial Surgeon receives £350 a year and a horse, with forage allowance; but no private practice is allowed without special permission.

Falkland Islands.—There are two appointments. The Colonial Surgeon is paid at the rate of £350 per annum, with £25 as Health Officer. The Assistant Colonial Surgeon is paid at the rate of £400 per annum without quarters. Part of the salary is provided from private sources. Private practice is allowed to the Colonial Surgeon, and to a lesser extent to the Assistant Colonial Surgeon.

Leave and Passages.—In the East African Protectorates leave of absence on full salary is granted in the normal case after a tour of residential service (of not less than 20 nor more than 30 months) to an amount of five days for each completed month of residence (or 2½ days when for any reason the officer is not returning to East Africa) exclusive of the periods of the voyages to and fro. Officers serving in Uganda, Zanzibar, or in certain stations in the East Africa and Nyasaland Protectorates are allowed six or three days' leave respectively in respect of each month of service. In Somaliland special leave regulations exist which provide for an officer taking leave approximately every year. Free first-class passages are provided for the officer only. In the Malay Peninsula two months' leave of absence with full salary may be granted in respect of each year's service, and this leave may be accumulated up to a maximum of eight months. Additional leave on half pay may be granted on special grounds. If an officer on the occasion of his first leave is in receipt of a pensionable salary of less than £500 a year, he is granted a free return passage to the United Kingdom. In Hong-Kong leave of absence on half salary may be granted after 4½ years' service, and a portion of such leave may be commuted, if the Governor agrees, for half the amount on full pay. Leave of absence in excess of 10 months at a time will not be granted, but an extension may be allowed for ill-health or very urgent private affairs.

Subject to the necessities of the service, leave of absence on half salary may be granted to officers in other Colonies outside tropical Africa after a period of six years' resident service without any special grounds. Officers of the Fiji and Western Pacific service proposing to spend their leave in Europe may receive a grant in aid of passage expenses of £60. Leave may be given before the expiration of the due period in case of serious indisposition, or of urgent private affairs. In the absence of special grounds, the leave must not exceed one-sixth of the officer's resident service; on special grounds it may exceed that period by six months. In addition to the above, vacation leave on full pay may be granted, if no inconvenience or expense is caused thereby, not exceeding three months in any two years. In the case of Fiji and the Western Pacific and the Falkland Islands, 4½ months' leave may be granted in any three years.

On first appointment an officer whose salary and fees together do not exceed £500 a year will, except in the case of a few Colonies possessing Representative Assemblies, be provided by the Crown Agents for the Colonies with free passages to the Colony for himself and his wife and children, if any, not exceeding four persons besides himself. The officer so appointed will be required to execute an agreement binding him to repay the cost of the passage or passages so obtained in the event of his leaving the Government service within three years. This rule applies also to officers appointed to the Malay Peninsula and Hong-Kong. An officer taking leave out of the Colony has to provide his own passages.

Pensions.—Officers on the pensionable establishment in the East African Protectorates are at liberty to retire on attaining the age of 50 years. Earlier retirement in the event of ill-health is also provided for. Pensions are computed on the scale of one-sixtieth of the average annual salary of the retiring officer's fixed appointments for three years prior to retirement, but for purposes of calculating pensions two years' service is reckoned as service for three years. In most of the other Colonies an officer holding a pensionable appointment may be allowed in the case of ill-health to retire on a pension after ten full years' resident service; otherwise he must have attained the age of 55. For ten full years' resident service fifteen-sixtieths of the average annual salary of the retiring officer's fixed appointments for three years prior to retirement may be awarded, to which one-sixtieth may be added for each additional year's service; but no addition will be made in respect of any service beyond 35 years. For pension purposes absence on vacation leave counts as full service, and leave on half pay as half service. In a few cases the retiring age is 60, and the pension after ten years' service is ten-sixtieths instead of fifteen.

West African Medical Staff.

The medical services of the West African Colonies and Protectorates—namely, the Gambia, Sierra Leone, the Gold Coast (including Ashanti and the Northern Territories), and Nigeria—form one service under the above name. All the medical officers for the service are selected by the Secretary of State for the Colonies, and are on one list for employment and promotion. As in other Colonies, applicants must be between 23 and 35 years of age and possess a double qualification, but preference is given to those over 25. The higher grades are usually filled by promotion from the lower.

The grades and emoluments of officers of the staff are as follows:—

The Director of the Medical and Sanitary Service in Nigeria receives a salary of £1400 a year, with a duty allowance at the rate of £280 a year.

Principal Medical Officer: The Principal Medical Officers receive salaries as follows: In the Gold Coast and the Southern Provinces of Nigeria £1200 a year, with a duty allowance at the rate of £240 a year. In Nigeria (Northern Provinces), £1100 a year, with a duty allowance at the rate of £220 a year. In Sierra Leone, £1000 a year, with a duty allowance at the rate of £200 a year. There is no Principal Medical Officer in the Gambia.

Deputy Principal Medical Officer: There are four appointments of this grade, three in Nigeria and one in the Gold Coast. Salary at the rate of £900 a year, rising by annual increments of £25 to £1000 a year, is attached to these appointments, together with a duty allowance at the rate of £180 a year.

Senior Sanitary Officer: There are four appointments of this grade, two in Nigeria, one in the Gold Coast, and one in Sierra Leone. Salary at the rate of £900 a year, rising by annual increments of £25 to £1000 a year (in Sierra Leone to £950 only), is attached to these appointments, together with a duty allowance at the rate of £180 a year.

Provincial Medical Officer: There are seven appointments bearing this title (four in Nigeria, two in the Gold Coast, and one in Sierra Leone), with salary at the rate of £800 a year, rising by annual increments of £25 to £900 a year, and duty allowance at the rate of £160 a year.

Senior Medical Officer: There are 20 appointments of this grade, with salary at the rate of £600 a year, rising by annual increments of £25 to £750 a year, and a duty allowance at the rate of £120 a year.

The Senior Medical Officer of the Gambia draws staff pay at the rate of £120 a year, in addition to duty pay, but is not allowed private practice.

Sanitary Officer: There are seven appointments of this grade, with salary at the rate of £700 a year, rising by annual increments of £25 to £800 a year, and a duty allowance at the rate of £140 a year.

Medical Officer: The salary attached to this grade is at the rate of £400 a year, rising by annual increments of £20 to £500 a year, with duty allowance at the rate of £80 a year. Medical Officers who have served for five years and are recommended for a higher rate of salary are required to take a special course of study for three months. If they obtain satisfactory certificates at the end of the course they are placed, on completing six years' service, on a scale of salary at the rate of £525 a year, rising by annual increments of £25 to £600 a year, with duty allowance at the rate of £100 a year. A Medical Officer who has served for three years on the maximum salary of this scale (£600) without obtaining promotion is eligible for the grant of further annual increments of £25 up to a total maximum salary of £750 a year.

Special appointments: The Director of the Medical Research Institute, Lagos, receives a salary of £600 a year, rising by annual increments of £25 to £800 a year, with a duty allowance of £120 a year. Salary at the rate of £500, rising by annual increments of £25 to £600 a year, is attached to about ten posts (those of Pathologist at Accra, Assistant at the Medical Research Institute, Lagos, and Medical Officers of Health at various places), irrespective of the seniority of the officer holding the appointment. In addition to the duty pay (£100 a year), staff pay at the rate of £100 a year is also attached to these posts; and the holder of the appointment draws half of the staff pay during leave of absence, the remainder being drawn by his locum tenens.

Leave and Passages.—The ordinary tour of residential service is one year, followed by leave with full pay during the voyages to and from England, and for four or two months clear in England, according as the officer is returning for further service in West Africa or not. If an officer is detained beyond the year, additional leave is given with full pay for ten days in respect of each completed month beyond twelve, whether he is returning or not. If he is invalided before the end of the year, the leave with full pay is for the voyages and for ten or five days in respect of each completed month, according as he is returning or not. Leave granted on the understanding that an officer will return is known as "return leave," and any pay drawn in respect of such leave is liable to be refunded if he does not return. Leave may be extended with half pay for a period not exceeding four months on the ground of ill health, or without pay on that or other grounds. Free passages are given to all officers who are granted leave, and free passage is also given on first appointment, subject to the officer signing an agreement under which he is liable to refund its cost if he relinquishes his appointment for any other reason than physical or mental infirmity, or is removed for misconduct, within three years from the date of his arrival in West Africa. Half pay is given during the voyage out on first appointment.

All officers of the Staff, except Principal Medical Officers, Deputy Principal Medical Officers, Provincial Medical Officers, Sanitary Officers, and a few other officers holding special appointments, are at present allowed to take private practice, provided that it does not interfere with the efficient performance of their official duties, but it is within the power of the Governor to withdraw or suspend the privilege in such places and for such periods as he may consider desirable. Private practice does not exist at the majority of stations, and as a general rule, subject to the exigencies of the service, stations where there is private practice are allocated to senior members of the staff.

Pensions and Gratuities.—On attaining the age of 50 years, or after 18 years' service (of which at least 12 must have been residential), an officer is qualified for a pension calculated at one-fortieth of the last annual [2] salary for each year of service. If invalided after a minimum

[2] Except that the pension of an officer who has been promoted within three years of his retirement is calculated on the average of his salary for the last three years.

of seven years' service, he is qualified for a pension calculated at the same rate. If invalided before completing seven years' service, he is qualified for a gratuity not exceeding three-quarters of a month's salary for each six months of service; provided that he has been confirmed in his appointment. For the purpose of calculating the amount of these pensions and gratuities, leave of absence without salary is not counted, while leave with half salary is counted at the rate of one month for every two months of such leave. An addition, representing the value of free quarters, is made to the officer's salary. This addition is as follows: To salaries of £400 a year, an addition of £40; to salaries above £400, but not exceeding £500, an addition of £50; to salaries above £500, but not exceeding £700, an addition of £60; to salaries above £700, but not exceeding £900, an addition of £70; to salaries exceeding £900, an addition of £80. In addition to the ordinary regulations, an officer of the West African Medical Staff enjoys the following special privilege. At the end of nine years (of which not less than six must have been residential) he will be permitted to retire with a gratuity of £1000, or at the end of 12 years (of which not less than eight must have been residential) with a gratuity of £1250. All claims to pensions are, however, forfeited on the receipt of such a gratuity. In the event of an officer dying in the service after completing the period of residence qualifying him for the smaller or the larger of these gratuities, a sum equal to the gratuity in question will be paid to the credit of his estate. Officers are not allowed to take their wives out with them until they have acquired experience of the local conditions, and have obtained the sanction of the Governor. Passages for wives and children are not provided.

Candidates for medical appointments in West Africa are allowed to express a preference for any particular Colony or Protectorate, and their wishes in this respect will be borne in mind and met as far as possible, but they are liable to be posted in the first instance, or transferred afterwards if necessary, to any other West African Colony or Protectorate at the discretion of the Secretary of State. Candidates who wish to be posted to the Northern Provinces of Nigeria should be able to ride. Candidates should on no account apply for, or accept, a West African appointment in the expectation of ultimately being transferred elsewhere, as the number of such transfers is exceedingly small. No applications for transfer can be entertained until an officer has served for five years in the West African Medical Staff, and officers desiring to be transferred must be prepared to find that medical salaries in other Colonies are lower than in West Africa. Only a small proportion of applicants succeed in obtaining a transfer. Officers who may be transferred to pensionable appointments under the Crown elsewhere than in West Africa do not forfeit their claim to pension in respect of their West African service on final retirement, provided they have been members of the Staff for at least 12 months.

Instruction in Tropical Medicine.—Every candidate selected for appointment will, unless the Secretary of State decides otherwise, be required to undergo a course of instruction for two or three months either at the London School of Tropical Medicine, Royal Victoria and Albert Docks, E. (near Connaught Road Station), or at the Liverpool School of Tropical Medicine at the University of Liverpool. The cost of the tuition fees, board, and residence during such instruction, amounting to a maximum of £48 8s. 10d., for three months, will be borne by the Government in the case of the London School; at Liverpool the cost of tuition will be borne by the Government, but candidates must make their own arrangements for board and lodging; an allowance of £2 a week will be paid to them monthly in arrear for this purpose. A daily allowance of 5s. (but no salary) will be paid to each candidate, monthly in arrear, during the course, and may be continued subsequently up to the date of embarkation. These payments must be refunded by the candidate if he declines to accept an appointment in any of the Colonies or Protectorates for which he may be selected, if he fails to obtain a certificate showing that he has satisfied the school authorities, or if he relinquishes the West African service for any other reason than mental or physical infirmity, or is removed for misconduct, within three years of the date of his arrival in West Africa. If at the end of the session there exist no vacancy in the staff to which a candidate can be appointed, he will be placed in a Reserve and granted an allowance at the rate of £200 a year until the occurrence of a vacancy.

Course of study for higher scale of salary.—The approved course of study is the three months' course of the West London Post-Graduate College or the London School of Clinical Medicine, Greenwich, in clinical medicine, clinical surgery, and pathology. Officers are allowed to substitute for this course either the course of study and examination for a recognised diploma or degree in public health, sanitary science, or State medicine; the course of study and examination for a further medical or surgical diploma or degree; or if the Governor, on the recommendation of the Principal Medical Officer, approves—a course of study in some special branch of medical or surgical practice (e.g., ophthalmology, dermatology, genito-urinary diseases), or an advanced course at the London or Liverpool School of Tropical Medicine. Whichever of these courses of study is selected, the necessary tuition and examination fees will be paid by the Colonial Government except in the event of an officer's deciding to enter for a further medical or surgical diploma or degree.

In conclusion it should be added that the West African Medical Staff, from which many British medical officers have been lent to serve with the Allied forces, receive terms and emoluments which compare favourably with other medical services of the Crown. Since the outbreak of war it has been the policy of the Secretary of State for the Colonies to refrain from calling the attention of the medical profession to recent improvements in the pay and prospects of the West African Medical Staff in order that the efforts of the naval and military authorities to obtain an adequate supply of medical officers should not be hampered in any degree. This consideration no longer applies as it has been so widely recognised by all the younger members of the medical profession that the claims of the Navy and Army are paramount.

DENTAL SURGERY.

ANYONE who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without the special licence; but it is of eminent advantage to take the L.D.S., otherwise few dental appointments at general or special hospitals or dispensaries are available. The subjects beyond those included in the general qualification are—Dental Anatomy and Physiology (Human and Comparative), one course; a separate course of Dental Histology, including the preparation of microscopical sections; Dental Surgery, one course; a separate course of Practical Dental Surgery; a course of not less than five lectures on the Surgery of the Mouth; Dental Mechanics, one course; a course of Practical Dental Mechanics, including the manufacture and adjustment of six dentures and six crowns; Dental Metallurgy, one course; a course of Practical Dental Metallurgy; Practice of Dental Surgery at a recognised school, two years, and a certificate of having been engaged during a period of not less than two years in acquiring a knowledge of Dental Mechanics (this may be obtained by apprenticeship to a duly qualified dental practitioner or in the mechanical department of a recognised dental hospital). The Dental Schools in London are the Royal Dental Hospital of London, the National Dental Hospital, Guy's Hospital Dental School, and the London Hospital Dental School. Most of the large provincial towns, where there are medical schools, have now dental hospitals.

The Registration of Dental Students is carried on at the Medical Council Office in London in the same manner as the existing registration of medical students, and subject to the same regulations as regards Preliminary Examinations. Candidates for a diploma in Dental Surgery must produce certificates of having been engaged during four years in professional studies, including two years' instruction in mechanical dentistry. The two years of instruction in mechanical dentistry, or any part of them, may be taken by the dental student either before or after his registration as a student, but no portion of such mechanical instruction will be counted as one of the four years of professional study unless taken after registration. The recommendations as to the course of study and examinations adopted by the General Medical Council in November, 1909, are under revision by the Council, but consideration of them is postponed until the Departmental Committee on the Dentists Act has reported.

It is necessary for anyone practising Dental Surgery in this country to be on the Register, and no foreign qualifications are recognised, except the Dental Diploma granted in Belgium after examination by the Provincial Medical Commission, provided the holder has obtained the grade of "Candidate in Medicine" at one of the four Belgian Universities. Certain dental qualifications granted in Australia and New Zealand are also registrable. The Royal Colleges of the United Kingdom and ten of the Universities grant degrees or licences in Dental Surgery.

THE REGISTERING BODIES IN DENTISTRY.

The Royal College of Surgeons of England grants a diploma in Dental Surgery under the following regulations, which apply to all candidates who have registered as dental students after Jan. 1st, 1897. Candidates are required to pass three examinations: the Preliminary Science Examination, the First Professional Examination, and the Second Professional Examination. I. Preliminary Science Examination.—This is identical with Part I. of the First Examination of the Examining Board in England. Candidates who commenced professional study on or after Oct. 1st, 1913, must pass the Preliminary Science Examination before commencing the courses required for the Second Professional Examination. II. The First Professional Examination.—The candidate must produce evidence of instruction in Dental Metallurgy and Practical Dental Mechanics. The Examination consists of Part I. (Mechanical Dentistry) and Part II. (Dental Metallurgy), the examination in Dental Metallurgy being by written paper. The parts may be taken together or separately. III. The Second Professional Examination.—This is divided into two parts: (*a*) the General, (*b*) the Dental. The General part must be passed before the Dental portion. The instruction is obtained partly at a General Hospital and partly

at a Dental Hospital.—The Second Professional Examination consists of: Part I., General Anatomy and Physiology, General Surgery and Pathology; Part II., Dental Anatomy and Physiology, Dental Pathology and Surgery, and Practical Dental Surgery. There is a written and *vivâ voce* examination in each part and a practical examination as well in Part II. Exemption from the Preliminary Science Examination is granted to candidates who have passed an Examination in Chemistry and Physics for a degree in Medicine at a University in the United Kingdom, in India, or in a British colony. Exemption from Examination in Anatomy and Physiology is granted to candidates who have passed the Second Examination of the Examining Board in England or the corresponding Examination for any degree or qualification in Medicine or Surgery registrable under the Medical Act of 1886. Exemption from Examination in General Surgery and Pathology is granted to candidates who have passed the Examination in Surgery of the Examining Board in England or the corresponding Examinations of the Colleges and University above mentioned. The fee for the diploma is 20 guineas, and is payable as follows:—Preliminary Science Examination, 3 guineas; First Professional Examination, 7 guineas; Second Professional Examination, 10 guineas. Synopses of examinations and all further information can be obtained from the Secretary, Examination Hall, Queen-square, London, W.C. 1.

Royal College of Surgeons, Edinburgh.—Regulations giving a list of Preliminary Examinations recognised for obtaining the Licence in Dental Surgery, as well as of the subjects of the Professional Examinations, may be obtained from Mr. D. L. Eadie, Clerk to the Royal College of Surgeons, at 50, George-square, Edinburgh. Candidates must produce certificates of having, subsequently to the date of registration, been engaged for four years in professional studies and of three years' instruction in Mechanical Dentistry from a registered dental practitioner, except in the case of previously registered medical practitioners, when two years will be considered sufficient. Candidates must also have attended a course of instruction at a University or in an established school of medicine or in a provincial school specially recognised by the College as qualifying for the Diploma in Surgery. In addition they will be required to have attended in a recognised dental hospital, or with teachers recognised by the College, special courses of lectures and instruction in Anatomy and Physiology (Human and Comparative), Surgery, Pathology, Materia Medica, Dental Histology, and Practical Dental Mechanics and Metallurgy; two years' attendance at a dental hospital or the dental department of a general hospital recognised by the College. Practical instruction in Mechanical Dentistry from a registered Dentist, or in the Mechanical Department of a recognised Dental Hospital and School, for *three* years. Candidates who have passed the First and Second Examinations for the Triple Qualification will be exempt from the First Dental Examination, and will have the advantage of being admissible either to the Final Dental Examination or to the subsequent Examination for the Triple Qualification, or to both. But the First Dental Examination will not be held as equivalent to the First and Second Triple Examinations, and will admit to the Final Dental Examination only. Candidates who are Licentiates of this College or who may be registered medical practitioners will be required to produce certificates of attendance on the special subjects only and will be examined in these only for the dental diploma. First Professional Examination: The candidate must have attended the required courses. The examination embraces (1) Chemistry and Physics; and (2) Anatomy and Physiology. The fee is £5 5*s*. for the complete examination, and £3 3*s*. is payable for each division. In all cases of rejected candidates the fee for re-entry is £3 3*s*. Second Examination: The candidate must have attended the remaining courses of the curriculum, must produce certificates showing that he is 21 years of age, and must pay a fee of £10 10*s*., for re-entry £5 5*s*. The examination embraces (1) Surgery and Medicine; and (2) the special subjects of Dental Anatomy and Physiology, Dental Surgery and Pathology, Dental Materia Medica, Dental Mechanics and Dental Metallurgy, with a practical as well as the written and oral examinations in the subjects of Dental and Oral Surgery, Pathology, and Mechanics. The candidate will be tested in the Treatment of Dental Diseases, in Operative Dentistry, the Administration of Anæsthetics, Orthodontics, and in Prosthetic and Mechanical Dentistry. Candidates who claim exemption from the First Dental Examination on the ground of having passed the First and Second Triple Qualification Examinations or other recognised examinations will, before being admitted to the Second Dental Examination, be required to pay the total fee of £15 15*s*. payable for the dental diploma. Fees and schedules must be lodged with the Clerk not later than one week before the examination.

Royal Faculty of Physicians and Surgeons of Glasgow.—The regulations as to certificates, curriculum, number, and subjects of examinations, fees, &c., are in effect similar to those of the Royal College of Surgeons of Edinburgh, but embrace Dental Bacteriology. Candidates can enter for the First Examination in three divisions, the first embracing Physics and Chemistry, the second Dental Metallurgy and Dental Mechanics, and the third Anatomy and Physiology. The examination in Dental Mechanics is practical; and there is at the Final Examination an examination in Practical Dentistry conducted in a dental hospital. Copies of regulations, &c., to be obtained from Mr. Walter Hurst, Registrar, Faculty Hall, 242, St. Vincent-street, Glasgow.

Royal College of Surgeons in Ireland.—Candidates for the Licence in Dental Surgery are required to pass two professional examinations. Before the First Examination the candidate must produce evidence of having attended courses in Theoretical and Practical Chemistry, including Metallurgy and Physics, at a recognised institution; of having been registered as a medical or dental student by the General Medical Council; and of having attended courses of instruction in the following subjects at a recognised school of medicine: (*a*) Anatomy Lectures; (*b*) Dissections with Demonstrations; (*c*) Physiology, including Dental Physiology; (*d*) Practical Physiology and Histology, including Dental Physiology and Histology, Human and Comparative. Before the Final Dental Examination the candidate must have been engaged during a period of two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist, or under the direction of the superintendent of the Mechanical Department of a recognised Dental Hospital, and have attended, at institutions recognised by the College for the purpose, the following courses of instruction: (*a*) Dental Surgery and Pathology, Orthodontia, and the Materia Medica and Therapeutics applicable to Dental Surgery. Lectures. Two courses. (*b*) Dental Mechanics. Lectures. Two courses. (*c*) Dental Anatomy. Lectures. One course. (*d*) The practice of a Dental Hospital, or of the Dental Department of a General Hospital. Two years. He must also have attended Clinical instructions at a recognised General Hospital during the ordinary teaching sessions (nine months), and have been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a medical or dental student. One year's *bonâ-fide* apprenticeship with a registered dental practitioner, after being registered as a medical or dental student, may be counted as one of the four years of professional study. He must be 21 years of age.

In the First Dental Examination candidates will be examined in (A) Physics and Chemistry, including Practical Chemistry and Metallurgy. (B) Anatomy, Physiology, and Histology—General and Dental. All the subjects may be passed at the same time, or they may be passed in two groups, (A) and (B). The examination is partly written, partly *vivâ voce*, and partly practical.

In the Final Dental Examination candidates will be examined in General Pathology, Medicine, and Surgery; Dental Surgery, and Dental Pathology, with the Materia Medica and Therapeutics applicable to Dental Surgery; Dental Mechanics and Metallurgy; Orthodontia. Candidates must pass in all the subjects at one examination. The examination is partly written, partly *vivâ voce*, and partly practical, and includes the examination of patients and the performance of dental operations. Candidates are required to provide their own instruments and gold for filling. The First Dental Examination will commence on the first Mondays in the months of February, May, and November. The Final Dental Examination will commence on the second Mondays in the months of February, May, and November. The total fee for the Diploma in Dental Surgery

is 20 guineas. Candidates must pay the fees for examinations from which they are exempted, unless when such exemptions have been granted in virtue of examinations passed before the Conjoint Board in Ireland.

University of Birmingham.—The teaching of Dentistry is undertaken by the University acting in association with the Birmingham Dental Hospital and the Birmingham Clinical Board. The instruction at the Dental Hospital is carried out under the direction of the University Dental Clinical Board, so that students may fully qualify themselves for the Dental Diploma (L.D.S.) of this and other universities and licensing bodies. There is a special and well-equipped Dental Museum and Laboratory. An Entrance Exhibition, value £37 10*s.* is awarded annually at the commencement of the winter session. The following are the regulations for Degrees in Dentistry:—1. The degrees conferred by the University are those of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.). 2. All candidates for these degrees must pass the same Matriculation Examination as that required from candidates for Medical Degrees. 3. The degree of Bachelor of Dental Surgery is not conferred upon any candidate who has not obtained a Licence in Dental Surgery. The candidate is not eligible for the degree until a period of 12 months has elapsed from the passing of his examination for the Licence in Dental Surgery. Of this period at least six months must be spent in the dental department of a general hospital approved by the University. 4. *A.* In addition to the Licence in Dental Surgery the candidate must produce evidence that he has attended the courses required by medical students of the University in the following subjects and passed the Examinations held in the same for Medical and Surgical Degrees: (*a*) Chemistry and Practical Chemistry, (*b*) Physics and Practical Physics, (*c*) Elementary Biology, (*d*) Anatomy and Practical Anatomy, and (*e*) Physiology and Practical Physiology. *B.* That he has passed the class examinations in: (*f*) One Special Course of Lectures on Medicine, (*g*) One Special Course of Lectures on Surgery, and (*h*) Pathology and Bacteriology. *C.* That he has attended courses and passed the class examinations in: (*k*) Dental Histology and Patho-Histology, (*l*) Comparative Dental Anatomy, and (*m*) Dental Surgery and Prosthetic Dentistry. *D.* That he has received instruction in the Clinical Examination of living cases at the dental department of a general hospital for a period of not less than six months. 5. The Final Examination will deal with the subjects in Classes *C* and *D*. 6. On the expiration of 12 months from the date of passing the Examination for the Degree of Bachelor of Dental Surgery, the candidate will be eligible for that of Master of Dental Surgery. 7. For this degree candidates will be required to submit a thesis containing original work and investigations in some subject connected with Dentistry, which thesis shall be submitted to examiners to be nominated by the Dental Advisory Board.

University of Bristol.—Candidates for the degree of Bachelor of Dental Surgery must be not less than 21 years of age and shall have pursued the courses prescribed by University regulations during not less than five years, of which three shall have been passed in the University, and shall have been registered as dental students by the General Medical Council. All candidates for the degree of B.D.S. are required to satisfy the examiners in the several subjects of four examinations. The First Examination: The subjects are Chemistry, Physics, and Zoology, and the curriculum extends over one year.* The Second Examination: The subjects are Dental Mechanics, Dental Metallurgy, and Dental Materia Medica, and the candidate shall produce evidence of having served for two years an approved pupilage in Dental Mechanics. The Third Examination: The subjects are Anatomy, Physiology, and Histology, Dental Anatomy, and Dental Histology. The Final Examination: The subjects are Medicine and Surgery, Dental Surgery (including Prosthetics), Operative Dental Surgery, and Dental Bacteriology. Degree of Master of Dental Surgery: Candidates shall be Bachelors of the University, shall present a Dissertation on some subject of Dental Surgery to be approved by the Examiners, and pass an examination in Dental Surgery. Diploma in Dental Surgery: Candidates need not be undergraduates, but shall be registered dental students before being admitted to any professional examination; the curriculum extends over four years. A two years' pupilage in Mechanical Dentistry is required, and four examinations must be passed, the subjects of which differ only from those of the B.D.S. in that Zoology is not required for the First Examination, and Medicine is not required for the Final Examination. Candidates who are already registered medical practitioners shall be further exempted from study and examination in Physics and Chemistry, Anatomy, Physiology and Histology, Medicine, and General Surgery.

University of Durham.—Every candidate for the Licence in Dental Surgery must be registered as a dental student. There are four Examinations. The subjects are:—*First:* (*a*) Chemistry; and (*b*) Physics. *Second:* (*a*) Dental Mechanics, Theoretical and Practical; (*b*) Dental Metallurgy. *Third:* (*a*) Anatomy; (*b*) Physiology and Histology; (*c*) Dental Anatomy and Dental Histology; and (*d*) Dental Materia Medica. *Final:* (*a*) Surgery; (*b*) Dental Surgery, including Prosthetics and Orthodontia; (*c*) Operative Dental Surgery, Practical Examination; and (*d*) Dental Pathology and Bacteriology. A candidate before presenting himself for examination is required to furnish certificates of instruction in the following subjects, attended after registration as a dental student at recognised Colleges or Schools:—*First Examination:* Chemistry and Physics. *Second Examination:* Dental Mechanics and Dental Metallurgy. *Third Examination:* Anatomy, with Dissections; Physiology; Histology; Dental Anatomy and Physiology; Dental Histology; and Dental Materia Medica. *Final Examination:* Dental Hospital Practice (two years); General Hospital Practice (nine months); Medicine Lectures (two terms); Surgery Lectures (two terms); Dental Surgery and Pathology (a course of not less than 20 lectures); Dental Bacteriology (three terms); Operative Dental Surgery (not less than 12 lectures); and Anæsthetics (a course of not less than one month).

Before admission to the Final Examination each candidate must furnish evidence (1) of having attained the age of 21 years; (2) of having undergone a three years' pupilage in Mechanical Dentistry with a registered dentist; and (3) of having been engaged in professional study for at least four years subsequent to registration as a dental student. The examinations will be held concurrently with the medical examinations, and the fees payable by candidates are as follows: First Examination, £2 10*s.*; Second Examination, £2 10*s.*; Third Examination, £3 10*s.*; Final Examination, £3 10*s.*; fee for Licence, £3; total, £15. For re-examination: First Examination, £1 10*s.*; Second Examination, £2; Third Examination, £2 (in one part only, £1); Fourth Examination, £2. The practical examinations in dentistry will be conducted at the Newcastle Dental Hospital.

University of Leeds.—The degrees in Dental Surgery are Bachelor of Dental Surgery (B.Ch.D.) and Master of Dental Surgery (M.Ch.D.). All candidates for the degree of Bachelor of Dental Surgery shall be required to have passed the Matriculation Examination, to have pursued thereafter approved courses of study for not less than five academic years, two of such years at least having been passed in the University subsequently to the date of passing Parts I. and II. of the First Examination, and to have completed such period of pupilage or hospital attendance, or both, as may be prescribed by the regulations of the University. No candidate will be admitted to the degree who has not attained the age of 21 years on the day of graduation. The classes in the Department of Dentistry begin on Sept. 30th. The instruction in the Preliminary subjects of Chemistry, Physics, and Biology are given at the University in College-road. The classes in the other subjects and the systematic courses in Dental subjects are held in the School of Medicine of the University in Thoresby Place. The clinical instruction is given in the Dental Department of the Leeds Public Dispensary, which is affiliated with the University and recognised by the Royal College of Surgeons. Applications for the prospectus should be made to the Dean of the Faculty of Medicine.

University of Liverpool (*Liverpool Dental Hospital Clinical School and School of Dental Surgery*).—The University grants a Licence in Dental Surgery (L.D.S.) and degrees in Dental Surgery (B.D.S. and M.D.S.). The courses of systematic instruction are given in the University buildings, five minutes' walk from the Dental Hospital. The two institutions are now closely associated, and the manage-

* Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination for either the B.D.S. or the L.D.S., and will be regarded as having completed one year of study.

ment of the curriculum is in the hands of the Board of Dental Studies. The Dental Hospital, covering a site of 672 square yards, was opened in March, 1910, equipped in each department with every modern accessory and receives constant additions. The laboratory is in charge of a skilled dental mechanic under the supervision of the Director of Dental Education and Dental Staff, and students are able to undertake at the hospital the whole of their training in Mechanical Dentistry. The times of the lectures at the University are arranged to meet the convenience of students, thus allowing the maximum time for attendance upon Dental Hospital practice. The staff of the hospital includes 12 Dental Surgeons, three Demonstrators, six Anæsthetists, three House Surgeons, and a Curator. Fees: The composition fees are as follows: Licence course (L.D.S.): Composition fee £58 10*s*., for the course of other licensing bodies £61 10*s*., payable in two equal instalments, the first on entry, the second 12 months later. Two years' instruction in Mechanical Dentistry (pupilage) and two years' Dental Hospital Practice (combined), £100, or in two instalments of £52 10*s*. each. Degree course (B.D.S.): £67 10*s*. for all lectures (including Chemistry, Physics, and Zoology) in three instalments. Two years' dental hospital, £21; general hospital practice, £10 10*s*.; three years' mechanical instruction (pupilage), £105. Further information may be had from the Director of Dental Education, Mr. W. H. Gilmour.

University of Manchester.—In the University of Manchester the Dental Department forms an integral part of the Faculty of Medicine. This contains a series of laboratories, lecture rooms, and museums which will bear comparison with those of any other school in the kingdom, and the fullest opportunities for study are offered to students preparing for any of the professional examinations. Instruction adapted to the requirements of students preparing for the B.D.S. Degree and the Dental Diplomas of the University, the Royal College of Surgeons of England, and of other licensing bodies is given during the Winter and Summer Sessions both at the University and at the Dental Hospital of Manchester adjoining the University. The required general hospital practice is taken at the Manchester Royal Infirmary. Women students are admitted to the classes in the Dental Department, and for them common rooms are provided. The composition fee for candidates for the University degree of Bachelor of Dental Surgery is 60 guineas, payable in two equal instalments at the beginning of the first and third years of studentship. The composition fee for candidates for the University Diploma in Dentistry is 55 guineas, payable in two equal instalments at the beginning of the first and third years of studentship. The composition fee for candidates for the L.D.S. of England is 60 guineas, payable in two equal instalments at the beginning of the first and third years of studentship. Students who have already served their apprenticeship with a private practitioner, and who propose to complete the final portion of their attendance at the University and at an approved dental hospital, will be required to pay the composition fee in two equal instalments at the commencement of the first and second years of studentship. The composition fee does not include the hospital fees, the examination fees, the fee for the conferment of the degree or the diploma, the registration fee, nor the fees for chemicals and chemical apparatus.

National University of Ireland.—This University grants the degrees of Bachelor of Dental Surgery and a degree of Master of Dental Surgery. A student may not be admitted to the Degree of Bachelor of Dental Surgery unless a period of not less than four years shall have elapsed from the date of his matriculation, during which period he must have pursued an approved course of study of not less than nine terms. For the degree of Bachelor of Dental Surgery candidates must pass four examinations, the first two being the same as those for the first and second examination in Medicine. The subjects of the third examination are Dental and Practical Pathology, Dental Surgery and Dental Medicine, the subjects of the fourth being Dental Surgery and Pathology, Dental Mechanics, Operative Dentistry, Orthodontia, and Dental Materia Medica. A candidate for the degree of B.D.S. must produce evidence of having been engaged during a period of two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist, or under professional direction in the mechanical department of a dental hospital approved by the University. A portion of or the entire period may be served before commencing study for the degree of B.D.S., but no portion so taken prior to commencement of study shall count as part of the four years of Dental Study. The degree of Master of Dental Surgery will not be granted until three years after the B.D.S. has been obtained.

TEACHING INSTITUTIONS IN DENTISTRY.

LONDON.

Royal Dental Hospital of London, School of Dental Surgery, Leicester-square.—A school of the University of London, and women are now admitted as students and are eligible for all hospital appointments and school prizes.—The school provides the special dental education required by the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 5 P.M., there being one staff for the morning and another for the afternoon of each day. Pupils are received for the training in dental mechanics recognised by the curriculum. The demonstrators at the commencement of each session give a course of lectures on Operative Dental Surgery. The six house surgeoncies are held for six months each and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the laboratory. There is an Entrance Scholarship in Chemistry and Physics of the value of £50. One Entrance Scholarship in Dental Mechanics and Metallurgy value £25, open to pupils of the Hospital only. One Entrance Scholarship of £25 in Dental Mechanics, open to pupils of private practitioners. The Saunders Scholarship of £20 awarded to second year students. The Storer Bennett Research Scholarship for Scientific Research in any branch of Dental Surgery, value £50, is awarded triennially. The Alfred Woodhouse Scholarship of £35 and the Robert Woodhouse Prize of £10 for Practical Dental Surgery. Prizes and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses, at the end of the summer and winter sessions. Fee for two years' hospital practice required by the curriculum, including lectures, £53 3*s*. in one payment, or £55 13*s*. in two yearly instalments. The curriculum requires two years to be passed at a General Hospital; the fee for this is about £60. Both hospitals can be attended simultaneously. For the lectures in Chemistry and Physics for the Preliminary Science Examination £10 10*s*. The fee for the instruction in Dental Mechanics and the two years' hospital practice required by the curriculum is £150 if paid in one instalment, or 150 guineas if paid in three equal instalments. The fee for tuition in Dental Mechanics is 50 guineas per annum; for one year's hospital practice £21. The Winter Session opens on Oct. 1st.

University College Hospital Dental School.—Corner of Great Portland and Devonshire-streets, W.—Students are entered as students of University College Hospital and, as such, attend the classes of Chemistry, Physics, Anatomy, and Physiology in University College, which is a few minutes' walk from the Dental Department in Great Portland-street, hitherto known as the National Dental Hospital. The First Dental School to admit Women Students. Practical courses to comply with the R.C.S. curriculum are held. Clinical Lectures and Demonstrations are given, and each student on entering passes through a preliminary course under a demonstrator. Two Entrance Exhibitions, of the value of £40 and £20, are open for competition. Prizes are open for competition at the end of each course of lectures. Fee for the full curriculum of four years, in all subjects required by the Royal College of Surgeons, 180 guineas, or in four instalments of 62, 41, 41, 41 guineas. A composition fee for medical men has been arranged covering the Two Years' Mechanical Work, Hospital Practice, and Lectures required by the curriculum of the Royal College of Surgeons amounting to 120 guineas. Hospital Practice to registered practitioners by special permission of Committee,

12 months, £15 15s. The Calendar, containing full information as to Lectures, Fees, Prizes, and Subjects for the Entrance Exhibitions may be had on application to the Dean, who attends the Hospital on Tuesday mornings at 10.30.

Guy's Hospital.—The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. The Extraction Rooms: A new Dental Out-patient Department has been provided. There is ample accommodation for ordinary extractions and anæsthetic extractions, together with waiting- and retiring-rooms. Patients are admitted between 8.45 and 9.30 A.M., and are seen by the dental surgeon for the day, the dental house surgeon, the assistant dental house surgeon, and the dressers. The Conservation Room is open from 9 A.M. till 5 P.M. It has recently been entirely remodelled and greatly enlarged, giving a floor space of over 6000 square feet. It affords accommodation for about 100 dental chairs, with the necessary equipment of the most modern type, for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. The members of the staff attend every morning and afternoon to give demonstrations and otherwise assist students in their work in the Conservation Room and Mechanical Laboratory. The Probationers' Laboratory is supervised by two of the staff demonstrators, and instruction is given in operative dentistry on a "mannikin" to students during their first three months of study. Pupils in Dental Mechanics are received, and a graded, systematic, and full course of instruction, extending over two years, is carried out. Dental students have the opportunity of attending at this hospital the whole course of instruction required by the examining board for the L.D.S. Eng.—viz., two years' pupilage in dental mechanics, the special lectures and practice of the Dental Department, and the general lectures and practice of the Medical School. The fees for these two courses may be paid separately or together, or they may be combined with the fees required to be paid for the course for a medical diploma. Students who enter for a medical as well as a dental diploma are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge. Four Entrance Scholarships in Dental Mechanics of the value of £20 each are offered for competition annually, two in September and two in April, and prizes of the aggregate value of £47 are awarded for general proficiency and for skill in Practical Dentistry. A Dental Travelling Scholarship of the value of £100 is awarded every second year. Dental students are eligible for admission to the Residential College and enjoy the privileges of students in the Medical School. Application should be made to the Dean of the Medical School.

London Hospital.—This school is a part of the London Hospital and Medical College, and is fully equipped on the most modern lines and with the latest appliances. It provides a complete curriculum in all subjects for the L.D.S. Diploma, and is admirably adapted for the purpose of teaching. The Conservation Room is well lighted and ventilated and fitted with pump chairs of the latest pattern; the fountain spittoon at every chair has been specially designed and has attached to it a saliva ejector, hot and cold water, compressed air, gas and electric current, also a swing bracket to carry the students' cabinet. Electric sterilisers are supplied in each department and motor engines where required. The School possesses in addition to the Theatres, Laboratories and Museums in the College, a special Museum of Dental Anatomy and Surgery, Operative Dentistry, Prosthetic and Extraction Rooms, and Laboratories for Practical Dental Metallurgy and Dental Prosthesis. A systematic course of instruction in Dental Prosthesis is arranged for pupils. The up-to-date Laboratory contains every modern apparatus and is in charge of a skilled curator and his assistants. Connected with the Medical College and Dental School are a Library, Athenæum, Clubs' Union, Dining Hall with moderate tariff, Students' Hostel, and an Athletic Ground. For full particulars as to fees and course of study advised apply to the Dean, Professor William Wright, who will be glad to make arrangements for anyone wishing to see the Dental School and Medical College.

The above arrangements are subject to revision in consequence of circumstances arising out of the war.

London (Royal Free Hospital) School of Medicine for Women.—Full courses are arranged for women students for the study of dentistry, and in preparation for the Licence in Dental Surgery of the Royal College of Surgeons of England, at the London (Royal Free Hospital) School of Medicine for Women, in conjunction with the London Dental Hospital, Leicester-square, and the National Dental Hospital, Great Portland-street, W. The course is arranged as follows: First and second years: Chemistry, Physics, and Dental Mechanics. Third, fourth, and fifth years: Anatomy, Physiology, and Special Dental Courses, Courses in Medicine and Surgery, General Hospital Course, Dental Hospital Course. The combined fees at the London School of Medicine for Women and the National Dental Hospital are £180 if paid in one sum on beginning the course, or £191 if paid in three annual instalments. Bursary: The Council of the School will award annually (until further notice) an "Agnes Guthrie" Bursary of the value of £50 to a student fulfilling the required conditions, who enters for the full dental course. Candidates are required to send in applications on or before July 1st, to the Warden and Secretary, from whom a prospectus of the School and all particulars can be obtained.

PROVINCIAL.

Birmingham Dental Hospital.—The Dental Hospital was founded in 1858, and was recognised by the Royal College of Surgeons in 1880 for the teaching of Dental Students. Having an annual attendance of about 16,000 patients, it affords every advantage for students about to enter the profession to acquire a thorough practical knowledge, as required by the Medical Council. The present Hospital was opened on July 6th, 1905. It has accommodation for 50 students. The equipment is in accordance with the most modern requirements for the efficient teaching and practice of Dental Surgery. The operations performed annually average 35,000, including 5000 gold and other fillings, and many cases of crowns, bridges, porcelain inlays, and regulations. By arrangements with the Birmingham University and with the General and Queen's Hospitals the entire course of Lectures, Hospital Practice, &c., may be completed for an inclusive fee of £96 15s., or including Mechanical Pupilage, £186. The instruments and materials necessary for Hospital Practice cost about £28. The Composition Fee for the courses required for the L.D.S. of the University, or any of the Corporations alone, is £60, payable in two annual instalments at the commencement of the first and second years; that for the courses required for the L.D.S. and the Degree in Dentistry of the University is £75; that for the L.D.S. in combination with the M.R.C.S. and L.R.C.P. is £85; and that for the M.B., Ch.B., and B.D.S. is £95. All of these composition fees are payable in two annual instalments at the commencement of the first and second years. Each of these fees covers the cost of the courses given at the University for the qualifications indicated, but does not include fees for Hospital teaching. For two years' dental hospital practice the fee is 20 guineas, payable in two instalments of 10 guineas each at the commencement of the first and second (hospital) years respectively. For two years' mechanical pupilage, 85 guineas, which may be paid in two annual instalments of 50 and 35 guineas respectively; mechanical pupils may join for a probationary period of one month, fee 5 guineas, which is deducted upon payment of the full amount. For general surgical hospital practice, lectures, and demonstrations: Surgery, two winters, £10 10s. One Entrance Scholarship is offered annually of the value of £37 10s. It is awarded to the student who, entering for the Dental Degree of the University in October, or having entered not earlier than the previous April, shall pass the best examination in the subjects studied during his apprenticeship. Candidates must be under the age of 21 years. Application for admission, together with a certificate of birth, must be sent to the Dean of the Medical Faculty, Mr. W. Thompson Madin, on or before Oct. 15th.

Leeds Public Dispensary.—The Dental Department of the Leeds Public Dispensary is fully equipped to provide training for Dental Students, and affords every opportunity for the student to prepare for any of the Dental Degrees or Diplomas. The Demonstrator of Operative Dental Surgery instructs students during their probationary course. At the completion of this training students have patients allotted to them by the Demonstrator, and have

every opportunity of acquiring knowledge from the members of the Staff, two of whom are in attendance each day. The following prizes are awarded:—First year Students, value 2 guineas. Operative Dental Surgery Prize, value 5 guineas. Two prizes in Prosthetic Dentistry: (*a*) a prize, value 2 guineas, for first-year pupils; (*b*) a prize, value 5 guineas, open for competition to all Students. Extraction prize, value 2 guineas, open for competition to all Students. A prize in Orthodontics, value 5 guineas, is open to all students. Warden: Mr. Stephen D. Hey, to whom all communications should be addressed.

Dental Hospital of Manchester.—This Hospital is in association for teaching purposes with the University of Manchester and the Royal Infirmary, and is in the centre of a very large population. Courses of study are provided to meet the requirements of the various examining bodies, including those of the University of Manchester for the qualifications L.D.S. and B.D.S., and the L.D.S. of the Royal College of Surgeons of England. Clinical instruction is given by the members of the staff and by the house surgeons and demonstrators, and also by the honorary anæsthetists in the administration of nitrous oxide gas; a special class in anæsthetics is conducted by the clinical tutor in that subject.

A Travelling Scholarship, value £100, will be awarded from time to time. Ten prizes, varying in value from £2 to £8, are awarded annually.

For the whole course of hospital instruction for the L.D.S. (including two years' mechanical training) the fee is £100, or if paid in instalments £105. For the two years' Operative Course only, £21, or if paid in two instalments 21 guineas. For the whole course of hospital instruction for the B.D.S. degree (including mechanical training), £130, or if paid in instalments 130 guineas. Additional practice in Dental Mechanics may be taken by pupils who have already received their mechanical training elsewhere, at a fee of £20 for six months.

All the courses of instruction are open to women students.

Copies of the Prospectus will be forwarded on application to Mr. J. Hilditch Mathews, Dean.

Newcastle-upon-Tyne Dental Hospital and School.—This Hospital is centrally situated (within five minutes of the various colleges, infirmary, and railway station); the rooms are well lighted and thoroughly equipped for carrying on the work. Dental surgeons and an anæsthetist attend each morning. A tutorial dental surgeon is also in attendance. The Composition Fee for the special Dental Lectures and Dental Hospital Practice is £45 3*s.* if paid in one sum, or £46 4*s.* if paid in two instalments of £23 2*s.* The Composition Fee for the Lectures at the Colleges of Medicine and Science is 40 guineas; in addition to this there is a library and an athletic fee. Particulars of the fee for General Hospital Practice may be obtained from the Senior House Physician, Royal Victoria Infirmary, Newcastle-upon-Tyne. Medals and Certificates of Merit are granted to students showing certain standards of proficiency in the various classes at the Dental School. The prospectus of the Dental Hospital and School, containing full information, may be obtained from either Mr. J. T. Jameson, 12, Windsor-crescent, Newcastle-upon-Tyne, Dean, or Mr. James Coltman, 13, Ellison-place, Newcastle-upon-Tyne, Vice-Dean.

Devon and Exeter Dental Hospital, 24, Southernhay, West, Exeter.—Established 1880.—The hospital is open on Tuesdays, Wednesdays, and Thursdays, and patients are admitted between the hours of 9 and 11 A.M. Students attend the practice of the hospital under the control of the medical officers. Honorary treasurer, Mr. J. M. Ackland; secretary, Mr. Albert G. Littlejohn.

SCOTLAND.

The Incorporated Edinburgh Dental Hospital and School.—The Edinburgh Dental Hospital and School is located in a spacious and well-equipped building at 31, Chambers-street and offers special advantages to dental students. The General Courses required for the Dental Diploma may be taken in the Medical School of the Royal Colleges of Physicians and Surgeons or in the University schools. The hospital attendance and clinical instruction are taken at the Royal Infirmary. The University, Medical Schools, and Royal Infirmary are within three minutes' walk of the Dental Hospital. The special courses are taken in the hospital. The Dental Hospital practice, extending over two years, affords a student ample opportunity for a full acquaintance with every branch of dentistry. The hospital admits a limited number of indentured pupils. They receive their instruction in Mechanical Dentistry concurrently with the general and special courses. A premium of 60 guineas is payable with each such pupil. The practice and lectures of the hospital are recognised by, and qualify for, all the Licensing Boards. The cost of the hospital outfit of instruments is included in the Dental Hospital fee of £31 10*s.* The minimum cost of classes and Diploma for the whole course of dental instruction amounts to £93 12*s.* Those students who desire to take a Medical and Surgical Diploma in addition to the L.D.S. have in this school admirable facilities for so doing. The triple qualification of the Royal College of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow is recommended. The minimum cost of Professional Education, the Triple Qualification, and the Licence in Dental Surgery amounts to £167 14*s.* Further particulars can be obtained from the Dean, Mr. W. Guy.

Incorporated Glasgow Dental Hospital and School, 158, Renfrew-street, and 15, Dalhousie-street, Garnethill, Glasgow.—Lectures will be delivered on the following subjects: Dental Mechanics, Dental Metallurgy, Dental Anatomy and Physiology, Dental Surgery and Pathology, Anæsthetics, Operative Technique, Dental Bacteriology, Operative Dental Surgery, Dental Histology, Orthodontia, and Crown and Bridge Work. Fees for two years' hospital practice £18 18*s.* Composite fee for Lectures and Hospital Practice £40. The hospital is opened daily from 5 to 7 P.M. (Saturdays excepted). Students may only enrol during the months of April or October. Prospectus may be had from the Secretary, D. M. Alexander, 186, St. Vincent-street, Glasgow.

Glasgow Royal Infirmary (Dental Department).—Mr. W. Taylor attends at the Royal Infirmary at 9 A.M. on Wednesdays and other days as arranged, and gives a course of instruction in Dental Surgery. The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry with Metallurgy, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Clinical Surgery, six months; Dental Surgery, six months, and attendance for two years on the dental department of the hospital. The attendance on the Dental Clinic is free to students of the hospital.

IRELAND.

Incorporated Dental Hospital of Ireland, Lincoln-place, Dublin.—All Dental Students who have passed their First Dental Examination in the Royal College of Surgeons in Ireland (or an equivalent examination or examinations) are admissible to the Clinical Instruction of the Hospital. In addition to Clinical Instruction and Special Demonstrations, courses of lectures are given at the hospital on Dental Surgery and Pathology, Mechanical Dentistry, the Administration of Anæsthetics, Orthodontia, Dental Anatomy, and Dental Materia Medica. Practical instruction is also given in Anæsthetics. In addition to the longer courses of hospital attendance, courses of three months' duration will be given to surgeons intending to practise in the Colonies or remote country districts, or in the Army and Navy.

Fees.—Dental Hospital Practice (each year), £12 12*s.*; Lectures, £6 6*s.*; Composition Fee, £15 15*s.* per annum. In addition to the above courses registered dentists who are members of the British Dental Association will usually be permitted to take out a three months' course for a fee of 6 guineas. The course in practical Dental Mechanics can be taken in the Hospital Laboratory. Further particulars can be obtained from the Dean.

UNIVERSITY OF BRUSSELS.—This University grants its M.D. degree to such foreign candidates as are already duly qualified in medicine and surgery in their own countries, provided they pass the three examinations imposed. For the present, owing to the war, examinations at the University are for internal students only.

DIPLOMAS IN STATE AND TROPICAL MEDICINE.

As usual we include in the Students' Number of THE LANCET an epitome of the instruction given at various universities and centres of medical education to medical men desiring to obtain diplomas in sanitary science, public health, State medicine, and tropical medicine. During the war some of this work has been suspended, for both teachers and taught being already registered medical men have been required in other spheres. But the public health of the country and of our colonial dependencies must be maintained, for this is one of our greatest guarantees of ultimate success in the struggle of endurance; and the machinery for the special education of public medical servants exists, as appears from what follows, and is ready to resume full activity at the earliest opportunity.

Resolutions, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," have been adopted at various times by the General Medical Council from 1902 to 1911. Certain universities and corporations grant qualifications in Tropical Medicine which have not as yet been made registrable by statute.

University of Oxford.—An examination, conducted partly in writing, partly *vivâ voce*, and in each subject partly practical, is held in (Michaelmas[1] and) Trinity Term in the following subjects:—General Hygiene, General Pathology (with special relation to Infectious Diseases), the Laws relating to Public Health, Sanitary Engineering, Vital Statistics. The examination is in two parts, which may be taken together or separately; but Part I. must be passed either before or at the same examination as Part II. The fee for admission to the examination is £5 for each part. Successful candidates are entitled to receive the Diploma in Public Health.

The First Part of the examination will comprise (*a*) a written paper of three hours in Chemistry and Physics; (*b*) a three hours' practical and *vivâ voce* examination in Chemistry and Physics.

The Second Part of the examination will consist of the following parts:—(*a*) Two written papers, each of three hours, dealing with General Hygiene (including Sanitary Engineering, Vital Statistics, and the Laws relating to Public Health); (*b*) a practical and *vivâ voce* examination in General Hygiene; (*c*) a written paper of three hours in Pathology and Bacteriology; and (*d*) a three hours' practical and *vivâ voce* examination in Pathology and Bacteriology.

Candidates in Part I. of the examination will be required to produce a certificate (1) of Laboratory Work in Chemistry as applied to Hygiene.

Candidates in Part II. will produce the following further certificates: (2) of a Practical Knowledge of the Duties, Routine and Special, of Public Health Administration; (3) of having had Practical Instruction in Bacteriology, and the Pathology of the Diseases of Animals transmissible to Man; and (4) of having attended the practice of a Hospital for Infectious Diseases at which opportunities are afforded for the study of the Methods of Administration. The names of candidates must be sent to the Assistant Registrar of the University, Clarendon Building, Oxford, to whom applications for any further information should be addressed.

University of Cambridge.—Two examinations in so much of State medicine as comprised in the functions of medical officers of health are held during the year. The examination is divided into two parts and demands proficiency in all the branches of study which bear upon the duties of medical officers of health. The examinations in both parts will be oral and practical, as well as in writing. Candidates may present themselves for either part separately or for both together at their option; but the result of the examination in the case of any candidate will not be published until he has satisfied the examiners in both parts. Marks of distinction will be placed against the names of candidates who have specially distinguished themselves in either (1) general principles of hygiene; (2) bacteriology; (3) chemistry in Part I. of the examination; or (4) the second part of the examination, which has reference to State Medicine and to the applications of Pathology and Sanitary Science. Every candidate will be required to pay a fee of £6 6*s*. before admission or readmission to *either part* of the examination, but candidates who have presented themselves before the year 1896 will be readmitted to either part on payment of a fee of £5 5*s*. Candidates must before admission to either part of the examination produce evidence of having satisfied provisions (1), (2), and (3), and before admission to Part II. having satisfied provision (4), above mentioned.

All applications for further information respecting examinations and the courses of study should be addressed to Mr. J. E. Purvis, the Chemical Laboratory, Pembroke-street, Cambridge.

Two Examinations in Tropical Medicine and Hygiene are conducted yearly by the State Medicine Syndicate of the University of Cambridge. The examinations are held in Cambridge early in January and in the middle of August. Each examination will extend over four days.

Any person whose name is on the Medical Register is admissible as a candidate to the examination provided (I.) that a period of not less than 12 months have elapsed between his attainment of a registrable qualification and his admission to the examination; (II.) that he produce evidence, satisfactory to the Syndicate, that he has diligently studied Pathology (including parasitology and bacteriology) in relation to Tropical Diseases, Clinical Medicine, and Surgery at a Hospital for Tropical Diseases, and Hygiene and Methods of Sanitation applicable to Tropical Climates. As evidence of study and attainments a candidate may present to the Syndicate (1) any dissertation, memoir, or other record of work carried out by himself on a subject connected with Tropical Medicine or Hygiene; (2) any Certificate or Diploma in Public Health or Sanitary Science he may have obtained from a recognised Examining Body. Such evidence will be considered by the Syndicate in determining whether he is qualified for admission to the examination and by the examiners in determining whether, if admitted, he shall be included in the list of successful candidates.

The examination will be partly in writing, partly oral, and partly practical and clinical (the clinical part will be conducted at a hospital for tropical diseases, at which cases will be submitted for diagnosis and comment), and will have reference to the nature, incidence, prevention, and treatment of the epidemic and other diseases prevalent in tropical countries. Every candidate who passes the examination to the satisfaction of the examiners will receive from the University a diploma testifying to his knowledge and skill in tropical medicine and hygiene. The fee for the examination is £9 9*s*., and applications should be addressed to Dr. Graham-Smith, Medical Schools, Cambridge. The examination for the Diploma in Tropical Medicine and Hygiene will be discontinued after 1918 till the end of the war.

University of London.—Candidates for the M.D. degree may offer State medicine as a subject in which to graduate. Certificates must be produced showing that a course of practical instruction has been attended for the prescribed period, and that the course has included such chemical, microscopical, and meteorological work and exercises as more especially relate to sanitation. The attendance includes six months' practical instruction in a laboratory and six months' instruction in public health administration under the supervision of a medical officer of health, and three months' attendance on the practice of a hospital for infectious diseases. The examination consists of papers in State medicine, including hygiene, school hygiene, and forensic medicine; a paper in medicine; an essay; and a two days' practical examination. Candidates must satisfy the examiners both in the papers and in the practical tests. A *vivâ voce* examination may be held at the discretion of the examiners. In connexion with this degree the various metropolitan medical schools hold regular classes under teachers of Public Health and Sanitary Science, such instruction being also used to obtain the various diplomas of other Universities and of those Royal Corporations which grant them.

University of Durham.—Candidates for the degree of Bachelor of Hygiene (B.Hy.) must be at least 22 years of age, registered, and a graduate in Medicine of a recognised university. They must spend six months at Newcastle-upon-Tyne studying Comparative Pathology, Practical Bacteriology, Sanitary Chemistry, and Physics, and have to pass an

[1] The examination in Michaelmas Term is suspended during the war.

examination in Sanitary Chemistry, Physics, Comparative Pathology, Sanitary Legislation, Vital Statistics, Nosology, Climatology, Meteorology, Distribution of Health and Disease, Sanitary Medicine and Practical Hygiene. The fee for the examination for the degree of B.Hy. is £10 10*s.* and for the degree £6 6*s.* Candidates for the degree of Doctor of Hygiene (D.Hy.) must have acquired the degree of Bachelor of Hygiene, must for two years subsequently have been engaged in Public Health administration, or in research work relating to Public Health. The fee for the examination for the degree of D.Hy. is £5 and for the degree £6 6*s.* The regulations for examination for the Diploma in Public Health (D.P.H.) are the same as those for the degree of Bachelor of Hygiene, except that the candidate is not required to be a graduate in Medicine of a recognised University and the course of study need not be passed at Newcastle-upon-Tyne. The fee for the examination is £10 10*s.* and for the diploma £3.

Victoria University of Manchester.—An examination in Public Health is held twice yearly. The examination is in two parts and is written, oral, and practical. Candidates may present themselves for Parts I. and II. separately or at the same time provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination. The fee for each part is £5 5*s.*, and must be paid on or before July 1st in each year. For any subsequent examination in the same part the fee will be £3 3*s.* Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a Diploma in Public Health. The examinations will begin about the end of March and the middle of July in each year. Holders of the Diploma in Public Health are eligible for examination for the Certificates in School Hygiene and Factory Hygiene after attending the prescribed periods of study and hospital practice.

University of Birmingham.—The University grants a degree of B.Sc. in Public Health and also a Diploma in the same subject on the following conditions: Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health by conforming to all the requirements laid down for candidates for the Diploma in Public Health, except that after graduating in Medicine all courses of study must be taken out in the University, and they must, in addition, have attended a three months' course of Geology in the University. The examinations will be held in the months of March and June and will consist of two parts, each part being written, oral, and practical. No candidate will be allowed to pass Part II. until he has passed Part I. Candidates may enter for Parts I. and II. separately or at the same time. The fee for each part of the examination is £5. Medical Officers of the Royal Navy who have attended courses in Hygienic Chemistry, Bacteriology, and Public Health at the Naval Medical School, Greenwich, will be admitted to the examinations for the Diploma in Public Health, whether they have previously been students at the Birmingham School or not; and the same applies to officers of the Royal Army Medical Corps who have studied Chemistry and Bacteriology at the Staff College and pursued the further course of study approved by the General Medical Council.

University of Liverpool.—The University grants a Degree in Hygiene (M.H.) and a Diploma (D.P.H.), and every facility is afforded for training in Sanitary Science and State Medicine. The curriculum for the Degree extends over a period of two years, the first of which is devoted to laboratory instruction and practical classes (including those for the Diploma); the second being devoted to advanced study and research. The D.P.H. curriculum fees are: Chemistry, £5 5*s.*; Bacteriology, £5 5*s.*; Practical Sanitation, £15; Infectious Diseases, £3 3*s.* The courses may be taken out at any time, and students are allowed to work daily in the laboratories.

The University grants a Diploma in Tropical Medicine. Three courses of instruction are given every year. Two of these last for three full months—the Lent Course from Jan. 6th to April 5th and the Autumn Course from Sept. 15th to Dec. 13th. The Third Course, an Advanced Course, lasts one month, from June 1st to the 30th. At the end of each full course an examination is held by the University for its Diploma of Tropical Medicine (D.T.M.), which is open only to those who have been through the course of instruction of the school. The examination lasts three days and consists (1) of papers on Tropical Medicine, Tropical Pathology, and Tropical Sanitation and Entomology respectively; (2) of a clinical examination; and (3) of an oral examination. The advanced course consists entirely of Practical and Clinical Laboratory Work, given at the laboratory at the University. The fee for the full course of instruction is 13 guineas, with an extra charge of 10*s.* 6*d.* for the use of a microscope if required. The fee for the examination is 5 guineas. Applications should be made to the Dean of the Medical Faculty, University of Liverpool. Two University Fellowships of £100 a year each are open to students of the school, amongst others. Accommodation for research work is to be had at the University Laboratory. The Mary Kingsley Medal is awarded by the school for distinguished work in connexion with Tropical Medicine. The new laboratories are completed and ready for occupation on the termination of the war.

University of Leeds.—The University grants a Diploma in Public Health, and every facility is afforded for training in Sanitary Science and State Medicine. The examination, which is held twice in each year—namely, in June and December—is in two parts, and is written, oral, and practical. Candidates may present themselves for Parts I. and II. separately or at the same time, provided that no candidate be allowed to pass in Part II. unless he has already passed in Part I. Fees—The fee for each part is £5 5*s.*, and for any subsequent examination in the same part £3 3*s.* Instruction in Sanitary Chemistry is given in the second and third terms and in Bacteriology during the first and second terms. Practical work under arrangement with the Leeds City Council. Prospectus can be obtained from the Dean of the Medical School.

University of Bristol.—Diploma in Public Health. Candidates must be at least 23 years of age, shall be fully registered medical practitioners of not less than 12 months' standing as such, and shall have passed the examination prescribed by regulation. The examination is divided into two parts. The subjects of the First Part are Chemistry as applied to Public Health and Pathology and Bacteriology. Candidates for the First Part shall, during six months after having obtained a registrable qualification, have received practical laboratory instruction in Hygienic Chemistry, in Bacteriology, and in the Pathology of the Diseases of Animals Transmissible to Man. The subjects of the Second Part are: Public Health and Epidemiology, Sanitary Law, Vital Statistics, and Sanitary Reporting.

University of Edinburgh.—Two degrees in Science in the Department of Public Health are conferred by the University of Edinburgh—viz., Bachelor of Science in Public Health and Doctor of Science in Public Health. A Diploma in Tropical Medicine and Hygiene is also granted. Candidates for the degree of B.Sc. in Public Health must be graduates in Medicine of a recognised University, and must pass two examinations, for the first of which they must, after graduation in Medicine, have worked for at least 20 hours per week during a period of not less than eight months, of which at least five consecutive months must be in the Public Health Laboratory of the University of Edinburgh and the remainder either there or in a laboratory recognised by that University; they must also have attended courses of instruction in Physics and Geology in some Scottish University. Candidates are not admitted to the Second Examination sooner than six months after having passed the First Examination, nor sooner than 18 months after having taken their degree in Medicine, and they must have attended two separate courses in Public Health in some University of the United Kingdom or in such medical school or Indian, Colonial, or Foreign University as may be approved for the purpose by Edinburgh University, each course consisting of 40 lectures at least; one of which courses shall deal with medicine and the other with engineering, each in its relation to public health. The subjects of examination include Laboratory work, Physics, Geology, Medicine in its application to Public Health, Sanitation, Sanitary Law, and Vital Statistics. Graduates who have held the degree of B.Sc. in Public Health from the University of Edinburgh for a term of

five years may offer themselves for the degree of D.Sc. in Public Health in that University. They must then present a Thesis and pass an examination in Public Health. The fees are £3 3*s*. for the First and £3 3*s*. for the Second B.Sc. Examinations, and £10 10*s*. for the degree of D.Sc.

University of Aberdeen.—The Diploma in Public Health (D.P.H.) is conferred only on graduates in Medicine of a University in the United Kingdom not less than 12 months after medical graduation. Every candidate must produce evidence of having attended, after graduation in Medicine, during a period of six months, practical instruction in Hygiene and Bacteriology in laboratories approved of by the University, together with having during six months (whereof three months must be distinct from the period of laboratory instruction) been diligently engaged in acquiring a practical knowledge of the duties, routine and special, of Public Heath administration under the medical officer of health of a county or large urban district. He must have regularly attended for three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. He must also have obtained practical instruction in the drawing and interpretation of plans. The diploma is conferred after an examination in Public Health held in March and July of each year. The fee is £5 5*s*.

University of Dublin (*Trinity College*).—The Diploma in Public Health is conferred, after examination, on the following conditions. The candidate must be a registered medical practitioner and have obtained a registrable qualification at least nine months before the examination. The candidate must have completed, subsequently to obtaining a registrable qualification, four months' practical instruction in a chemical and bacteriological laboratory or laboratories approved by the University, must have studied practically outdoor sanitary work for six months under an approved officer of health, and must have spent three months' attendance at a fever hospital where opportunities are afforded for the study of methods of administration. A special prospectus and a list of recognised laboratories may be obtained by application to the Registrar of the School of Physic, Trinity College, Dublin.

National University of Ireland.—At this University there is a Diploma in Public Health and a B.Sc. in Public Health. The Diploma may be granted to matriculated or non-matriculated students of the University who shall have completed approved courses of study and shall have passed the prescribed examinations, provided that it shall not be granted except to a registered medical practitioner. Candidates may present themselves for the examination after an interval of not less than 12 months from the time of obtaining a registrable qualification. The curriculum extends over a period of not less than nine calendar months. Every candidate must produce a certificate that he has attended practical instruction in a laboratory, approved by the University, in Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man. The examination consists of two parts, which may be passed separately or together. Part I. comprises the following subjects: Chemistry, Meteorology and Climatology, and Sanitary Engineering and Architecture. Part II. comprises the following subjects: Bacteriology, Hygiene, Sanitary Law, and Vital Statistics. The examination in each part will be oral and practical as well as written.

For the B.Sc. in Public Health a candidate shall not be admitted unless he (*a*) shall have received the degrees of M.B., B.Ch., and B.A.O. at least one year previously; (*b*) shall have pursued an approved course of study in the Faculty of Medicine; and (*c*) shall have passed the prescribed examination. In addition to D.P.H. course the candidate will be required to take up (1) a Special Course of Pathology; (2) Bacteriology; and (3) Advanced Course in Hygiene. Each of these courses lasts three months.

University of Belfast.—A Diploma in Public Health is given by examination. Every candidate must produce evidence that, after obtaining a registrable qualification, he has during six months received practical instruction in an approved laboratory in which Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man are taught. After obtaining a registrable qualification every candidate must produce evidence that he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. The examination must have extended over not less than four days, one of which shall have been devoted to practical work in a laboratory, and one to practical examination in, and reporting on, subjects which fall within the special outdoor duties of a medical officer of health. The examination will be held once yearly, Part I. in March and Part II. in June. The first part of the examination will have reference to the general principles of sanitary science, and the second part to State Medicine and to the applications of Pathology and Sanitary Science. The fee for each part is 1 guinea.

Royal College of Physicians of London and the Royal College of Surgeons of England.—The following are the regulations for obtaining the Diploma in Public Health: The examination consists of two parts. The first part of the examination takes place in January and July, and the second part in January and July. The fee for each part is £10 10*s*., except for those who are diplomates of the Royal Colleges, who pay £6 6*s*. for each part. A candidate intending to present himself must give 14 days' written notice to the Secretary, at the Examination Hall, Queen-square, London, W.C. 1. He will be admissible to examination in Part I. on producing evidence (1) of having been in possession of a registrable qualification for at least 12 months; (2) of having attended thereafter practical instruction in a laboratory recognised by the Examining Board in England for at least 240 hours during a period of six months; and (3) of being at least 23 years of age. A candidate will be admitted to Part II. of the examination on producing evidence (1) of having been diligently engaged in acquiring a practical knowledge of Public Health administration during six months under certain specified conditions; (2) of having attended during three months the clinical practice of a hospital for infectious diseases; and (3) of being at least 24 years of age.

The examination for the Diploma in the Diseases and Hygiene of the Tropics has been discontinued during the war.

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, the Royal Faculty of Physicians and Surgeons of Glasgow.—All candidates for the Diploma in Public Health must have a qualification which has been registered under the Medical Acts. Candidates must have attended not less than four calendar months' practical instruction in Chemistry and Bacteriology in a recognised laboratory or laboratories, must have studied outdoor sanitary work for six months under a medical officer of health or other sanitary officer; and must give evidence of attendance for three months at the practice of a Hospital for Infectious Diseases, at which he has received instruction in the methods of administration. The examination consists of two parts, and candidates may enter for both at one period or for either separately. The First Part includes (*a*) Laboratory Work (Chemistry and Bacteriology), (*b*) Physics and Meteorology; and the Second Examination embraces (*a*) Report on Premises visited, (*b*) Examination at Fever Hospital, (*c*) Examination at Public Abattoir, (*d*) Written and Oral Examinations on Epidemiology and Endemiology, (*e*) Vital Statistics and Sanitary Law, and (*f*) Practical Sanitation. The fee is 12 guineas for both examinations, or 6 guineas for either of them. A fee of 3 guineas is payable by rejected candidates for either examination. The examination is held twice yearly, in May and October. The published regulations provide detailed synopses of the subjects of examination. The Registrar for Edinburgh is Mr. D. L. Eadie, 50, George-square, and for Glasgow Mr. Walter Hurst, 242, St. Vincent-street.

Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland.—Every candidate for the Diploma in Public Health must be a registered medical practitioner. He must subsequently to qualification (1) receive six months' laboratory instruction in Chemistry, Bacteriology, and the Diseases of Animals transmissible to man; and (2) during six months practically study outdoor sanitary work under a medical officer of health, and shall as an additional requirement attend a hospital for infectious diseases. Candidates are examined on four days, commencing on the first Monday of February, May, and November. The examination comprises the following subjects:—Hygiene, Chemistry, Meteorology and Climatology, Engineering, Vital Statistics, Sanitary Law, and Bacteriology. The fee for the examination is £10 10*s*. For further particulars apply to Alfred Miller, Secretary, Committee of Management; Office, Royal College of Surgeons, Dublin.

The Numerical Position of the Medical and Dental Professions.

THE NUMBER OF MEDICAL STUDENTS.

THE number of students in actual attendance on courses of instruction in preparation for medical degrees or diplomas in the medical schools of the United Kingdom is now accurately known from the returns submitted by the General Medical Council to the Ministry of National Service. These show that although the total number of fourth- and fifth-year students at the present time is still perilously low—in the case of the former a bare three-quarters of the minimum yearly entry into the profession considered desirable by the Director-General of National Service to make up for the wastage—yet this is more than compensated by the increased numbers of students in the early years, and the total number has, in fact, steadily increased during the last two years, as the following schedule shows:—

Total Medical Students in Attendance at the Medical Schools of the United Kingdom.

May, 1916	6103	October, 1917	7048
January, 1917	6682	May, 1918	7630

An analysis of these 7630 students into groups according to sex, attainment of military age, place of study, and seniority is given in a table submitted by the President of the General Medical Council on June 28th last, which we now reproduce in full, having printed a shortened form of it in THE LANCET of July 27th. The numerical proportion of men and women students can be seen from the table, and may be stated in percentages as follows:—

Percentage of Men and Women Students.

	Men.	Women.		Men.	Women.
First year	68	32	Fourth year	73	27
Second ,,	67	33	Fifth ,,	82	18
Third ,,	68	32	All years	71	29

from which it may be noted that the proportion of men and women entering on their medical study has remained practically constant during the last three years, although differing in the various regions of study. Among the students of all years in London 33 per cent. are women, in England and Wales (including London) 31 per cent., in Scotland 36 per cent., and in Ireland 18 per cent.

THE NUMBER OF REGISTERED MEDICAL PRACTITIONERS.

The total number of names on the Medical Register at the beginning of the present year was 43,819, distributed as follows between the various local registers:—

England ... 23,715, being 54 per cent. of the whole number.
Scotland ... 13,918 ,, 32 ,, ,,
Ireland ... 6,176 ,, 14 ,, ,,

The numbers added by registration, removed on evidence of death, and the totals remaining on the Register on the last day of each of the last five years are shown in the following table:—

Year.	Number added by registration.	Number removed on evidence of death.	Number of names on the Register on Dec. 31st.	Increase on the previous year.
1913	1168	746	41,940	501
1914	1433	1068	42,378	438
1915	1526	800	43,225	847
1916	1202	1005	43,481	256
1917	1134	831	43,819	338

The yearly additions in the last column do not agree precisely with the differences between the preceding columns, inasmuch as a certain number of names are removed from or replaced on the Register each year on formal grounds. It is noteworthy that during the last three years no name has been removed from the Register on account of its bearer ceasing to practise. So far the number of names on the Register has increased from year to year, but it is quite evident on referring to the numbers of medical students due to qualify in the years 1919–21 that this increase will not be kept up in those years unless, on the one hand, death is less active, or, on the other, there is a greater supply from medical schools outside the United Kingdom. A list is given later of the degrees granted in British possessions and in foreign countries, which are registrable in the colonial and foreign lists respectively of the Medical Register.

—	First year. Due to qualify in 1923.					Second year. Due to qualify in 1922.					Third year. Due to qualify in 1921.					Fourth year. Due to qualify in 1920.					Fifth year. Due to qualify in 1919.					Totals for all years.		
	Men.	Women.	Total.	Men under 18.	Men from places outside the U.K.	Men.	Women.	Total.	Men under 18.	Men from places outside the U.K.	Men.	Women.	Total.	Men under 18.	Men from places outside the U.K.	Men.	Women.	Total.	Men under 18.	Men from places outside the U.K.	Men.	Women.	Total.	Men under 18.	Men from places outside the U.K.	Men.	Women.	Total.
London District ...	285	202	487	118	41	211	137	348	15	28	167	150	317	—	27	195	66	261	—	29	389	53	442	—	93	1247	608	1855
England and Wales (including London)	592	329	921	273	50	472	256	728	44	40	362	226	588	3	44	300	116	416	—	42	514	92	606	—	105	2240	1019	3259
Scotland	393	222	615	214	37	329	259	588	76	23	319	185	504	—	52	231	129	360	—	49	315	103	418	—	71	1587	898	2485
Ireland	393	114	507	56	2	448	104	552	5	12	369	73	442	—	13	228	30	258	—	8	115	12	127	—	5	1553	333	1886
Total	1378	665	2043	543	89	1249	619	1868	125	75	1050	484	1534	3	109	759	275	1034	—	99	944	207	1151	—	181	5380	2250	7630

THE NUMBER OF REGISTERED DENTISTS.

The total number of dentists appearing upon the Dentists' Register for 1918 was 5524, the comparative figures for the last five years being—

Year.	Number added by registration.	Number removed on evidence of death.	Number of names on the Register on Dec. 31st.	Increase on the previous year.
1913	195	66	5276	135
1914	273	93	5426	151
1915	241	109	5453	27
1916	195	120	5512	59
1917	130	105	5524	12

As in the case of the Medical Register, certain removals and replacements of names are made on formal grounds, so that the third column cannot be accurately deduced from the two preceding.

Of the total 5524, 5495 are described in the Register as United Kingdom dentists, 11 as Colonial dentists, and 18 as Foreign dentists.

REGISTRABLE COLONIAL AND FOREIGN MEDICAL DEGREES.

UNDER the Medical Act, 1886, a number of medical diplomas granted in British Possessions entitle their possessor to be registered without further examination in the colonial list of the Medical Register. The conditions attached to such registration is that the holder of the colonial diploma obtained it when he was not domiciled in the United Kingdom or in the course of a period of not less than five years during the whole of which he resided out of the United Kingdom. These diplomas are as follow:—

BRITISH NORTH AMERICA.

Manitoba: College of Physicians and Surgeons, Member; University of Manitoba, M.D.
New Brunswick: Provincial Council of Physicians and Surgeons, L.M.S.
Newfoundland: Medical Board, L.M.S.
Nova Scotia: Provincial Medical Board, L.M.S.; Dalhousie University, M.D., C.M. (Halifax Medical College, M.D., C.M., if obtained prior to August 31st, 1911.)
Ontario: College of Physicians and Surgeons, Member. (To this can be added as additional qualifications the degrees in medicine of the Queen's University, Kingston; the Western University, London; and the University of Toronto.)
Prince Edward Island: Medical Council, L.M.S.
Quebec: McGill University, M.D., C.M.; Laval University, M.D.
Saskatchewan: College of Physicians and Surgeons, Member.

ASIA.

Ceylon: Medical College, L.M.S.
Hong Kong: University of Hong Kong, M.B., B.S.
India: University of Allahabad, M.B., B.S.; University of Bombay,[1] (1) L.M.S., (2) M.B., B.S., (3) M.D., (4) M.S.; University of Calcutta, (1) L.M.S., (2) M.B., (3) M.D., (4) M.S., (5) M.O.; University of Madras,[2] (1) M.B., M.S., (2) M.B., B.S., (3) M.D.; Punjab University, (1) L.M.S., (2) M.B., (3) M.D., (4) M.S.
Straits Settlements: King Edward VII. Medical School, Singapore, L.M.S.

AUSTRALASIA.

New South Wales: University of Sydney, (1) M.B., (2) M.D., (3) Ch.M.
New Zealand: University of New Zealand, (1) M.B., Ch.B., (2) M.D.
South Australia: University of Adelaide, (1) M.B., B.S., (2) M.D., (3) M.S.
Victoria: University of Melbourne, (1) M.B., (2) M.D., B.S.

EUROPE.

Malta: University of Malta, M.D.

Certain medical diplomas granted in foreign countries also entitle to registration in the foreign list of the Medical Register provided that the holder is not a British subject, or that, being a British subject, the diploma was obtained under domiciliary conditions similar to those attached to colonial diplomas. These diplomas are as follows, the date in parentheses being the year in which Part II. of the Medical Act, 1886, was applied to the country in question:—

Italy: Degrees of Doctor of Medicine and Surgery of all the Royal Italian Universities (1901).
Japan: Degrees of Bachelor of Medicine (Igakushi) and Doctor of Medicine (Igaku Hakushi) of the Imperial Universities of Japan; and the Degree of Bachelor of Medicine (Igakushi) of any Government or Prefectural special Medical College, or of a private special Medical College designated by a Minister of Education of the Empire of Japan (1905).
Belgium: Degrees of Doctor of Medicine of the Belgian Universities of Brussels, Ghent, Liége, and Louvain, which give legal authority to practise medicine, surgery, and midwifery in Belgium (1915).

The colonial list of the Medical Register at present contains some 900 names, the foreign list less than 150 names, of which the large majority are Belgian. We hope to publish later some account of these degrees and diplomas which, when registered, entitle the possessor to practise medicine within the borders of the United Kingdom.

[1] If obtained after June 25th, 1912, the degree must have been registered in the Presidency.
[2] If obtained after June 1st, 1916, the degree must have been registered in the Presidency.

OUR CURRENT NUMBER

Being almost exclusively devoted to information especially interesting to Students, we are necessarily compelled to defer the publication of communications on other important subjects.

We tender our best thanks to those gentlemen who have at considerable personal trouble kindly supplied us with the returns and prospectuses upon which the information given in this Students' Number of THE LANCET *relative to the various medical examining bodies, hospitals, and medical schools of the United Kingdom is based. We regret that in some cases, however, owing to proofs having been either not returned at all or too late, certain inaccuracies may be found.*

EDITORIAL NOTICES.

In consequence of the pressure on our space and the shortage of paper, the Editor may be compelled to abbreviate communications, as an alternative to their rejection, when time does not allow them to be reconsidered by their authors.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

Offices: 423, STRAND, LONDON, W.C. 2.

Communications, Letters, &c., to the Editor have been received from—

A.—Sir Clifford Allbutt, K.C.B., Cambridge; Mrs. V. Almond, Weston-super-Mare; Australian Imperial Force, Lond., D.M.S. of; Mr. C. Andrews, Leyton.
B.—Board of Trade, Lond., Asst. Sec. of; Messrs. John Bale, Sons, and Danielsson, Lond.; Capt. P. Bahr, R.A.M.C.
C.—Mr. F. R. Cave, Okehampton; Mr. J. Cabburn, Lond.; Charing Cross Hospital Medical School, Dean of; Mrs. A. K. Cyriax, Lond.
D.—Dr. H. Davies, Lond.; Dr. J. F. Devane, Limerick; Capt. S. C. Dyke, R.A.M.C.; Dental Tribunal, Lond., Sec. of.
E.—Capt. W. d'Este Emery, R.A.M.C.(T.)
F.—Factories, Chief Inspector of, Lond.; Capt. W. Fletcher, R.A.M.C.
G.—Capt. J. A. Glover, R.A.M.C.; Dr. L. Guthrie, Ockley; Messrs. C. Griffin and Co., Lond.; Mrs. M. Grieve, Chalfont St. Peter.
H.—Lieut.-Col. S. H. Henderson, I.M.S.; Mr. R. S. Hopkins, Lond.; Major R. A. P. Hill, R.A.M.C.; Capt. E. R. Hunt, R.A.M.C.
I.—Italian Embassy, Lond., Military Attaché of.
J.—Dr. J. H. Jones, Standford Dingley.
K.—Messrs. T. Kerfoot and Co., Bardsley; Dr. P. Kidd, Lond.
L.—Temp. Surg. J. Lambert, R.N.; Dr. R. E. Lord, Colwyn Bay; Local Government Board, Lond., Sec. of; Lister Institute of Preventive Medicine, Lond., Deputy Director of.
M.—Mr. J. E. R. McDonagh, Lond.; Mr. W. M. Mollison; Capt. W. MacAdam, R.A.M.C.; Metropolitan Asylums Board, Lond., Clerk of; Mr. G. Mayall, Bolton; Mansion House Council on Health and Housing, Lond.; Capt. A. Maude, R.A.M.C.; Ministry of Food, Lond.
N.—National League for Health, Maternity and Child Welfare, Lond.
O.—Col. M. D. O'Connell; Capt. J. R. O'Brien, R.A.M.C.
P.—Mr. S. Paget, Lond.; Señor D. Salvador V. de Castro Pérez, Granada; Dr. W. Prescott, Worthing.
R.—Royal Medical Benevolent Fund, Lond., Sec. of; Mrs. M. F. Rogers, Murthly; Dr. A. Routh, Lond.
S.—Messrs. Siemens Bros. and Co., Lond.; Capt. C. P. Symonds, R.A.M.C.; Mr. C. A. Parker, Lond.; Society of Apothecaries of London; Secretary of State for India, Lond.; Dr. H. Sutherland; St. George's Hospital Medical School, Lond., Acting Dean of; St. Mary's Hospital Medical School, Lond., Acting Sec. of.
T.—Mr. H. Teggart, Iona; Major G. Taylor, R.A.M.C.; Dr. J. Tatham, Oxted; Major P. Turner, R.A.M.C.
U.—University College Hospital Medical School, Lond., Sec. of.
V.—Mr. S. K. Vaidya, Lond.
W.—Mr. E. Whiston, Bath; Dr. F. P. Weber, Lond.; Dr. S. A. K. Wilson, Lond.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C. 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

SUBSCRIPTION RATES.

Special Terms for Position Pages.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—J. Behesnilian (Sect. II.), Charing Cross Hosp.; J. Gorsky (Sects. I. and II.), Westminster Hosp.; W. H. Haupt (Sect. I.), George Washington Univ.; B. A. M. Henderson (Sect. II.), Manchester and Charing Cross Hosp.; F. Lyth and H. Lyth (Sects. I. and II.), Manchester; H. E. Reburn (Sect. I.), King's College Hosp.; G. P. N. Richardson (Sects. I. and II.), Cambridge and St. Mary's Hosp.; W. H. Steavenson (Sects. I. and II.), Guy's Hosp.; and J. Stephen (Sects. I. and II.), Manchester.

Medicine.—H. Carter (Sects. I. and II.), London Hosp.; W. H. Haupt (Sects. I. and II.), George Washington Univ.; W. D. Macrae (Sects. I. and II.), London Hosp.; G. P. N. Richardson (Sects. I. and II.), Cambridge and St. Mary's Hosp.

Forensic Medicine.—J. F. E. Burns, Bristol; F. I. G. Edwards, Royal Free Hosp. and Liverpool; W. H. Haupt, George Washington Univ.; W. H. Steavensor, Guy's Hosp.

Midwifery.—F. I. G. Edwards, Royal Free Hosp. and Liverpool; I. R. Florence, Guy's Hosp.; W. H. Haupt, George Washington Univ.; J. H. Marriott, Manchester.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: J. Behesnilian, J. Gorsky, F. Lyth, H. Lyth, G. P. N. Richardson, W. H. Steavenson, and J. Stephen.

THE BELL FUND.—Dr. S. A. K. Wilson, 14, Harley-street, London, W.1, acknowledges a donation of £2 2*s.* to this Fund from Dr. Frank C. Shrubsall.

RESULT OF THE ENTRANCE SCHOLARSHIP EXAMINATIONS AT ST. THOMAS'S HOSPITAL.—Entrance Science Scholarships:—1st, £150, no award; 2nd, £60, M. C. Sivakara; honourable mention, N. G. Harris, Emrys Williams.

INSTRUCTION IN HOSPITAL ADMINISTRATION FOR THE DIPLOMA IN PUBLIC HEALTH.—A course of lectures and demonstrations in hospital administration, lasting three months, will be given at the Western Hospital of the Metropolitan Asylums Board, Seagrave-road, Fulham, London, S.W. 6, by Dr. R. M. Bruce, medical superintendent, on Tuesdays and Fridays, at 5 P.M., beginning Oct. 8th. The fee for the course is £3 3*s.*, payable to the clerk to the Metropolitan Asylums Board, Embankment, London, E.C. 4.

THE CODEX ADDENDUM, 1918.—The current issue of the *Pharmaceutical Journal* contains a list of alternative formulæ for the preparations temporarily withdrawn from the British Pharmacopœia on account of containing lard or vegetable oils. The Addendum has been prepared by the Codex Subcommittee of the Pharmaceutical Society, and is now published with its authority.

THE University of London Press announces the addition of four volumes to the series of Military Medical Manuals—viz.: "Disabilities of the Locomotor Apparatus, the Result of War Wounds," by Professor Aug. Broca, edited by Sir Robert Jones. "Electro-Diagnosis of War," by Professor A. Zimmern and P. Perol, edited by Dr. E. P. Cumberbatch. "Wounds of the Pleura and Lungs," by Professor R. Grégoire and Dr. Courcoux, edited by Lieutenant-Colonel C. H. Fagge, M.S. "Mental Disorders of War," by Professor Jean Lepine, edited by Dr. Charles Mercier.

MAUDSLEY NEUROLOGICAL CLEARING HOSPITAL.—The course of instruction in shell shock and war neuroses will be resumed on Sept. 20th at 3 P.M. No fees will be charged. Application should be made to Lieutenant-Colonel F. W. Mott, at the hospital, Denmark Hill, London, S.E.5.

POST-GRADUATE COLLEGE, WEST LONDON HOSPITAL.—During next week clinics will be held each week-day at 2 P.M., Wednesday, Friday, and Saturday also at 10 A.M.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee, held on Tuesday, August 13th, 24 cases were considered and £212 6*s.* 8*d.* voted to 22 of the applicants. The following is a summary of some of the cases relieved:—

Widow, aged 51, of M.B. Glasg. who practised at Sheffield and died in April of this year. Applicant was left entirely without means and her health is bad, suffering from chronic rheumatism. Daughter, aged 25, at home; son, 22, Second Lieutenant, prisoner of war; son, 19, in the Army, and allows his mother 3*s.* 6*d.* per week. Rent and rates, £30. Daughter has to remain at home to look after mother. Voted £4, with leave to apply again in October.—Daughter, aged 60, of M.R.C.S. Eng. who practised at Halesworth and died in 1904. Applicant's only income £30 from investments. In the winter suffers severely from bronchitis, so only able to earn a little in the summer. Pays £10 a year rent. Voted £12 in 12 instalments.—Widow, aged 39, of L.R.C.P. Edin. who practised at Alfreton, Derbyshire, and died in March, 1917. Applicant was left with two children, now aged 5½ and 3½ years. She earns £115 in a temporary post, and her father, who lives with her, pays the rent of the house. Asks for help towards education of children. The Guild will help if the Fund will give a small qualifying grant. Voted £4.

Subscriptions may be sent to the acting honorary treasurer, Dr. Samuel West, at 11, Chandos-street, Cavendish-square, London, W.1.

Notes, Short Comments, and Answers to Correspondents.

THE NEW INDIAN QUALIFICATIONS.

IN THE LANCET of Feb. 13th (p. 321) we stated the attitude of the General Medical Council towards the licences in medicine and surgery granted by certain Provincial medical faculties in India. At that time no general conclusion had been reached in regard to the admission by home licensing bodies to their own examinations of holders of the new Indian qualifications. We are now authorised to state in regard to the Conjoint Examining Board of the Royal College of Physicians of London and the Royal College of Surgeons of England, that—

1. A candidate who has passed the final examination for Membership of the State Faculty of Bengal is *not* allowed to sit for the final examination of the Conjoint Board without passing the second examination in anatomy and physiology.
2. A candidate who has passed one or more examinations of the Bengal Faculty, but has not obtained his diploma, is not exempted from any examination of the Conjoint Board.
3. A candidate who has obtained the Membership of the Bengal Faculty can enter for the second examination of the Conjoint Board on producing evidence of having completed the curriculum and obtained his diploma; and when he has passed the second examination of the Conjoint Board, he can proceed to the final examination if he completes two years of additional study at a recognised medical school and hospital in this country.
4. In every case the candidate must have passed a preliminary examination in general education, which fulfils the requirements of the Conjoint Board or of the General Medical Council.

The list is given on p. 309 of diplomas of Indian Universities which entitle their holders without further formality to registration in the United Kingdom.

HOW TO BECOME A WOMAN DOCTOR.

IN a little book of 130 pages, published by Messrs. Chas. Griffin and Co. at 3*s.*, Miss Emily L. B. Foster has put together some useful information for the woman who desires to be a doctor, as she has already done for the woman dispenser. Dr. W. J. Fenton, who as dean of the Charing Cross Hospital Medical School now has some practical knowledge of the working of a scheme of placing men and women students on an equality throughout their whole course, contributes a preface, in which he says:—

"The students work together on perfectly friendly terms, and there is every reason to believe that the experience will be to their mutual advantage: the result being medical practitioners soundly educated, with broad-minded and sympathetic views, both towards the public, which they will have to serve, and the profession, of which they will form a part."

Miss Foster herself contributes brief paragraphs on the History and Prospects of the Woman Doctor and on Co-education, and sketches a day in the life of a woman house physician. Otherwise the book contains nothing but a welcome statement of the facilities now open to women, along with extracts from the regulations of various diploma-granting bodies.

THE POSITION OF REGISTERED DENTISTS.

WE have given elsewhere the number of names at present on the Dentists Register as 5524. Of the 5495 United Kingdom dentists, 1281 are registered on their own declaration as being in *bona fide* practice of dentistry, 7 of them possessing additional medical and surgical qualifications. Of the remaining 4214, 2446 are licentiates in dental surgery of the Royal College of Surgeons of England, 177 of English Universities, and 1128 possess Scottish and 463 Irish diplomas. 467 of the 4214, or 11 per cent., possess also surgical or medical qualifications. The special position of registered dentists in relation to the Military Service Acts has now been fully recognised by the Ministry of National Service in the appointment of a Special Dental Tribunal to deal with all applications for exemption by registered dentists. The membership of this Tribunal was given in THE LANCET of June 20th (p. 926), and its address is 19, Hanover-square, London, W.1.

VETERINARY SURGEONS AND NATIONAL SERVICE.

IN a circular (R. 225) issued to tribunals the Secretary of the Local Government Board states that, having regard to present military and civilian requirements, it has been decided to take no registered veterinary surgeon for military service except as a commissioned officer for employment in his professional capacity. The decision, as in the case of registered medical men and registered dentists, is subject to the condition that, if left in civilian employment, he is engaged on such veterinary work as is deemed to be of most value to the nation. A special tribunal, known as the Veterinary Tribunal, has been appointed for dealing with the cases of veterinary surgeons, to which any application for the grant, renewal, or review of exemption is now to be made. The address is 10, Red Lion-square, London, W.C. 1.

Thoughts ON THE EMPLOYMENT OF PREGNANT WOMEN IN MUNITION FACTORIES.[1]

BY MARY A. S. DEACON, M.B., B.S. LOND.,
MEDICAL OFFICER TO A NATIONAL FILLING FACTORY.

THE factory from which the following report was compiled is built on the site of a farm in flat, open and well-drained fields; there is an abundance of fresh air and sunshine. All the buildings are very well ventilated with cross and end-to-end through draughts, and the sanitary and bath accommodation is in excess of the Home Office requirements. The factory is particularly well managed; the canteen is good; the factory clothes are most suitable and made so as entirely to cover all the worker's private clothes.

The factory is situated a mile from the station and tram terminus, and all workers have of necessity to walk this mile as there is no other way of reaching their work. The exercise is most salutary for them, and it is surprising to see the difference in their general appearance noticeable after about six weeks' work with us.

A covered way is provided alongside the roadway for protection in rough weather, and this pathway has been well rolled so that it is always firm and dry.

Our workers are of the usual city type—undersized, badly developed, with very bad teeth and often anæmic. About 50 per cent. are married, and often these have their household duties to attend to after they get home at night. In spite of these drawbacks, after about six weeks' work, and hard work too, if they have the grit to stick it, they become more robust, less anæmic and much more healthy-looking in every way. I consider that this improvement is due to healthy exercise, well disciplined work, the good and abundant food supplied in the canteen at moderate price, and above all to the abundance of fresh air which they are obliged to get when working in this factory. The fresh air and hard work make them hungry, and getting good money they can well afford to obtain sufficient food. During their meal hour they have amusement, some days they dance and on others concerts are arranged. All workers are medically examined before being engaged, and if found suitable but with bad teeth these are extracted by the factory dentist before work is actually started.

During the nine months, June 1st, 1917, to Feb. 28th, 1918, I have kept records with a view to finding out the effect of the work on any woman who may become pregnant. Of the total number of women workers engaged in that period (1197) 575 were married and 622 single. The married women have been brought into the labour market for various reasons. Munitions factories have given them their opportunity, and factory managers have no alternative but to engage them.

THE NATURE OF THE PROBLEM.

The question is one which may be looked at from two standpoints: (*a*) under the enforced conditions due to the war; (*b*) post-war conditions.

As regards (*a*), seeing that it is essential for a certain percentage of married women to take up some form of work outside the home, it is equally essential for their medical welfare to be carefully studied, with a view to bringing about a set of conditions which will make it possible for them to carry on their work to the satisfaction of their employers, and without fear of injury to themselves or the future race. In so doing it should be possible to find by experience whether similar conditions could be applied in post-war days if the necessity for married women to work then should still exist.

In a factory such as ours the work is mostly arduous and heavy, but the factory management have had all operations classified into heavy, medium, and light operation, and they are also willing, if they have the vacancies, to put workers who are not fit for the heavier operation into the less arduous classes, so that I have been enabled in many cases (by this coöperation on the part of the factory management) to transfer pregnant workers from the heavy work to the lighter operation and so gather materials for this report.

The nature of the work also necessitates extreme cleanliness, and in this factory such cleanliness is enforced with the utmost rigour.

The question then arises in a factory of this kind, where so many married women are employed, whether when they may become pregnant it is better to dismiss them at once or to keep them at work until within a few weeks of their confinement. Up to the present I have not taken on new workers if they are pregnant, as I do not consider that they would become proficient before they had to leave, and this would be hardly fair to the factory.

THE QUESTION OF EFFICIENCY.

We will first study the question solely from the factory's point of view—"efficiency." The authorities of the factory might put forward the arguments—

(*a*) That the women were no longer capable of heavy work.
(*b*) That not being in good state of health their time-keeping and work record would be bad.
(*c*) That miscarriages might occur, which would disorganise the work at the time, and which also might lead to compensation claims.
(*d*) That in the event of there not being any suitable light work at which to employ them the women would not be worth their pay.

A natural prejudice would also be felt against seeing women about in such a condition, but this hardly amounts to a reason, and in a factory where about 90 per cent. of the workers are women should not even be a prejudice.

The answers to these arguments are:—

(*a*) The women need not be capable of very heavy work, as in most factories there are many lighter duties to which pregnant women could be put, and in which no strain is put upon the abdominal muscles, while they do not in fact necessitate as much energy as is required in household duties.

(*b*) The fear that the woman's time and work records would be bad at such times is one that in some cases, of course, may be justified, but if the upset is such as really to incapacitate her and to cause her to neglect her work, then there is nothing to compel her to stay if she wishes to leave, and nothing to prevent the factory dismissing her if really a negligent worker. On the other hand, some women feel better when in such a condition, and in all cases their health must be the better for regular and sufficient exercise, good food, and healthy occupation for their minds and bodies.

The time when the pregnancy is most likely to upset the health is during the first four months, when the condition cannot be diagnosed unless the worker comes to the factory doctor complaining of symptoms pointing to such a condition, and this she is not likely to do if she fears dismissal, so that bad time-keeping and slack work due to such causes cannot be eliminated, even in factories where dismissal is the rule.

A woman who is anxious to retain her work will do her best to attend regularly and to give as much satisfaction as possible in all her duties, and the mere fact that she is regular in her habits will probably keep her in better health, and so increase her capacity for work.

(*c*) Miscarriages are very unlikely to occur if the woman is encouraged to make her condition known to the factory doctor at as early date as possible, with a view to being transferred to, or retained in, work suitable to her condition, and if she is not in fear of dismissal she will be much more likely to report early. No factory could possibly obtain information as to the condition of its workers during the first three months of pregnancy excepting by the voluntary information of the workers themselves, and yet this is the period during which nearly all miscarriages occur, and is the most critical time during the whole period of pregnancy. No claim for compensation could possibly stand if it were shown that the factory authorities required the women to notify their condition to them as early as possible with a view to suitable work being found, and it would then be a woman's own fault if she continued her own heavy work against the known wishes of the management.

In our factory we have notices put in the changing houses and in the ambulance-rooms asking the women to notify the doctor as early as possible if they are pregnant, so that they may be placed on work which will avoid any risk of personal injury.

(*d*) The argument that the woman by doing other than her usual work is not worth her pay is answered by the statement that the disciplined and trained worker is more worth her pay even with a slight physical disability than the undisciplined and untrained worker who may take her place.

[1] Being part of a paper read at the Oxford Welfare Conference, August 6th–10th, 1918.

The factory arguments in favour of keeping on such women are:—

(*a*) That good feeling will be promoted if the workers know that the management have their actual welfare at heart, and are not penalising them for natural physical disabilities.

(*b*) That this mutual good feeling will produce better workers.

(*c*) That miscarriages will be actually fewer in a factory where the conditions are known at an early date, as such accidents are thereby prevented, along with their subsequent disorganisation of the factory work.

THE WORKERS' POINT OF VIEW.

From the workers' point of view it seems to me that most arguments must be entirely in favour of being kept on. The most cogent reasons are:—

(*a*) The worker should not be turned away from work that she is quite able and competent to do because of her condition, excepting in cases where the work is very heavy, but as in our factory (and also, I should think, in most other factories) there is alternation of work, and as the same woman may do various kinds of work, some suitable employment can usually be found for her.

(*b*) The worker will not be tempted to take drugs or to use other means to provoke miscarriage if she is free from the fear of losing work where she can earn a good wage, and being obliged either to drop out of the labour market altogether or to take on duller and less highly paid work because she cannot do without the money. I have heard of cases in which the worker when dismissed from a factory because of her condition has, in order to obtain bare necessities, gone rag-picking on some refuse heap and got into such a bad condition that both she and the child have been in great danger at the time of the actual confinement.

(*c*) If the worker continues at her more highly paid work she can afford to save money for the time during which she will be laid by, and can also probably then afford to take a longer interval after the confinement, when the rest is all-important both to herself and the child.

(*d*) During the pre-confinement period, if she earns good money, she can enjoy the better food which is so necessary to her condition. She shares the company and fellowship of her companions, so necessary to keep her cheerful, and by walking a mile to work obtains plenty of exercise and fresh air. The maintenance of the mother in a fit state of health and spirits is all-important to the health of the child to which she is to give birth. Several of the workers are reported as never having felt so well during former pregnancies or having had such good confinements or such healthy babies. In no case has the actual nature of their employment had the slightest detrimental effect.

The woman's arguments against staying on might be:—

(*a*) In some cases she might not feel well enough to turn out to work and to travel to and fro, but if she does not really feel well enough to do so, she is practically free to leave.

(*b*) The fear that she might miscarry. This fear will very probably be dispelled if the worker notifies her condition. As a matter of fact, the tables which I have prepared and give here in summary show that of the very few cases of miscarriage that we have had—only 15, including 2 premature births, during the whole of the nine months—13 were at very early dates before the factory authorities could have taken any steps toward a dismissal, as they could not possibly have known of the condition except by the voluntary information of the worker herself. Only two occurred while actually at work. I believe that some factories have had a lot of trouble in this way, but we have never had any real trouble of that kind; one baby was actually born in the ambulance-room, as the woman had miscalculated, but as the ambulance-room was equal to the occasion this did not matter. Another threatened miscarriage was arrested by suitable treatment, and the pregnancy continued until full term.

(*c*) A reluctance to staying among her fellow-workers.

THE QUESTION OF MATERNAL WELFARE.

From the State point of view the greatest question of the present day is the increase of the human race and infant welfare. And any measures are to be encouraged which tend to promote the greater well-being of the mother before and at the time of confinement, and the health of the coming generation. If the woman can keep in a more healthy condition, be better fed and happier in cheerful surroundings, this is all for the good of the State and is likely to raise the birth-rate. I contend that a woman who is struggling for an existence and is debarred from earning a good wage simply through her condition is being discouraged instead of helped at a time when she deserves all possible aid. She is thereby thrown into a condition of anxiety at a time when worry is a detriment and she is prevented from saving for a period of stress. In consequence the child suffers before and after birth.

Every working mother should be encouraged, if possible, to abstain from work for at least three months after confinement, so as to recover completely her normal state of health, and to nurse the baby during this time; but in practice this is very difficult, as the woman is often short of money and implores to be taken back. If the State can promote a scheme to keep the mother entirely in the home, so that she can feed and look after her children, so much to the good; but while she depends upon her individual exertion, no woman should be debarred from doing the best for herself and for unborn children. From a medical point of view reasonable work combined with exercise and good food are the proper preparation for childbirth.

I wish particularly to emphasise the fact that from a medical point of view no certain diagnosis of the woman's condition can be made during the first three months, unless she will tell you her own suspicions; and yet this is the period during which most risk is run and during which most miscarriages occur. Also this is the period in which measures are taken with a view to provoking miscarriage, if loss of work is feared, so that no factory can be free from such danger even if it dismisses all known cases of pregnancy, while the State will certainly be the loser of some of the coming generation.

SUMMARY OF RECORDS.

In the report that I have drawn up I have had 101 cases of women who became pregnant during the nine months of which I have kept records.

Of these 46 cases terminated successfully with 47 children before the end of February, 1918, when the report was made up. One woman had twins; 7 cases could not be traced but were all right when last heard of.

Thirty-four cases had not come off at the end of February, but of these 19 have terminated successfully since.

There were 2 premature births and 13 early abortions—that is, before the third month of pregnancy. Of the 2 premature cases one had operation for advanced carcinoma of cervix at 5 months and the other contracted syphilis at 6 months, the baby being born dead at 8 months.

The 13 miscarriages were all very early, from five to ten weeks. Of these, one patient fell out of bed while dreaming and miscarried three days later, another took "female pills" and fell downstairs, a third had had tuberculous trouble, and a fourth previous miscarriages.

It is very possible that other babies have been born who do not appear in my report, as other women may have had confinements without reporting their condition. It is, however, unlikely that there have been more miscarriages than I have recorded, as all workers who are absent for three days consecutively are visited at their homes and inquiries are made into the reason for such absence, so that miscarriages could hardly escape notice by reason of this factory regulation.

I am still keeping records of all such cases, and now that the workers do not fear dismissal and know that an interest is taken they willingly notify their condition. Thus they are kept under observation even after they leave, with the result that my next year's records will be more complete than those for the nine months to February, 1918. All the women whom I have seen since confinement report that they have had easy labours, healthy children, and that they never felt better while carrying.

One woman who worked until ten days before her confinement had the first healthy baby that she had ever had out of eight. Another had had 12 pregnancies, but only one other living child before this one. A third told me she had seven other children and that this was the healthiest one. All the women told me that they found the walk to work beneficial, and said that they had never felt so well before.

ARTS AND HANDICRAFTS EXHIBITION. — The exhibition which is organised annually by the *Englishwoman* will this year be held at the Central Hall, Westminster, from Nov. 13th to 23rd. The exhibition is designed to encourage home handicrafts, and has a distinct bearing on the employment of disabled soldiers. A number of social organisations, including the Church Army and the Y.M.C.A., use the exhibition for the sale of their hand-made productions.

THE LATE DR. J. S. COOPER.—The death occurred on August 15th, at his residence in Culter, of James Snowie Cooper, M.D. Aberd. After graduating at Aberdeen University in 1891 he practised for a time in Lancashire, and was then physician for three years at the Sanatorium, Banchory. Lately his health had precluded his practising his profession. He is survived by a widow, daughter of the late W. R. Bruce, D.D., minister of Newmachar, and one daughter.

METHODS OF CONTROL OF FRAGMENTS IN GUNSHOT WOUNDS OF THE JAWS.

BY H. P. PICKERILL, M.D., M.D.S.,
MAJOR, N.Z.M.C.; O.I/C. N.Z. SECTION, QUEEN'S HOSPITAL, SIDCUP.

IN considering the methods at our disposal for the control of the various fragments in gunshot wounds of the jaws, it is necessary first of all to review the forces producing the displacements which require subsequent reduction and control.

There are four factors concerned: (1) direction of missile; (2) size of missile; (3) muscular contraction; (4) fibro-cicatricial contraction (in later stages of untreated cases). The direction of the missile and the size of the missile are rather intimately connected; other things being equal, the larger the missile the more will be the gross displacement produced, and this in the direction of the missile; the fragments tend to be of large size, the number of them being, I think, strictly proportionate to the velocity of the missile. When, however, the wound is produced by a rifle bullet, we roughly get three effects: (1) the high-velocity bullet striking the bone at right angles to its surface will frequently drill it and produce radiating fractures with little or no displacement, and none in the direction of the missile; (2) the high-velocity bullet striking the bone at a tangent produces extreme comminution, and constitutes one of the most difficult forms of fracture we have to treat; (3) the low-velocity bullet which produces a local shattering with some displacement in the direction of the missile.

Muscular Action.

The various muscles which may exert a displacing force on the various fragments are, of course, well recognised, but many of the so-called depressors and elevators of the jaw exert important stresses in other directions, which become exaggerated when the continuity of the mandible is broken. A few years ago when I realised this double action of nearly all jaw muscles I calculated the direction of their forces after a large number of measurements by plotting the average measurements on a graph. (These plotted charts have unfortunately to be omitted for want of space.) The following illustrations demonstrate this.

The *temporal* muscle, which, of course, has an upward and backward pull, also exerts an outward pull of 2 cm. on each side.

The *masseter* likewise is not only an elevator of the mandible, but will pull a posterior fragment very much forwards and also considerably outwards, the latter stress being over 1·5 cm. on each side.

The *internal pterygoid* muscle is an elevator of the posterior fragment, but if unopposed would tend to pull it 4 cm. inwards on each side. This action, of course, is normally more than counteracted by the masseter and temporal actions, but occasionally owing to hyper-development of the internal pterygoid a state of equilibrium may be obtained, or even with the aid of other muscles the fragment may be tilted inwards.

The *external pterygoid* normally draws the condyle and interarticular fibro-cartilage forwards, but what is not usually recognised is that it has almost as much inward pull as it has forward—i.e., as 3 : $3\frac{1}{2}$. The direction is also always slightly upwards.

The *superior constrictor of the pharynx* has also a direct inward pull upon a posterior fragment, and if a patient is constantly using this muscle in swallowing for some days, it may be, after being wounded, it may produce a marked inward displacement of the ascending ramus. But, on the other hand, I have seen cases in which the displacement was said to be due to this muscle when it was clearly due to cicatricial contraction between the mandible and the tongue.

The *digastric* and *geniohyoid* muscles are normally depressors of the mandible, but when continuity is severed, especially in bilateral fractures in the anterior region, they tend to draw the fragments more backwards than downwards, and also by reason of their attachments to the hyoid being more widely apart than their insertion into the mandible, a symphysis fracture tends to be kept open at its lower end.

The *mylohyoid* muscles being attached in a fan-shaped manner to the inner surface of the mandible, tend to draw anterior fragments towards the middle line and to invert them, and since the mylohyoid muscle is a swallowing muscle, it is one which is frequently in action before immobilisation is usually brought about.

The muscles of *facial expression* (as distinct from the masticatory muscles) all have an inward moulding effect upon fragments of both jaws, and tend by their use to narrow and compress the dental arches in a backward direction. Many of these muscles, but especially the buccinators, are attached either directly or indirectly to both maxilla and mandible. The effect of these muscles is most seen in fractures of the upper jaw, the fragments of which on account of it are always drawn downwards and backwards. (This is frequently thought to be due to the effect of gravity alone, but the extreme difficulty of controlling the fragments unless the facial muscles are prevented from contracting shows that this is not so.)

But while these are the directions in which forces are normally exerted by the individual muscles, there are two important variations which tend to produce unexpected effects.

(*a*) Abnormally developed muscles, or muscles used exclusively after the wound, produce a variation of displacement from that expected. For instance, abnormally developed internal and external pterygoids may overcome the action of the masseter and temporal muscles, or if the fracture is just anterior to the attachment of the superior constrictor of the pharynx and the patient is continually swallowing small boluses before the fragments are fixed, the posterior fragment may be tilted inwards.

(*b*) The condition of the various groups of muscles at the moment of impact does, I think, have considerable effect upon the amount and direction of displacement. The condition being whether they are strongly contracted or flaccid at the time. For instance, if a man is "setting his teeth hard," doing some desperate deed when he is struck in the posterior third of the mandible, the posterior fragments will at once be strongly drawn upwards and outwards, and there will not be marked depression of the anterior portion. Whilst if the man is charging with his mouth open, shouting and excited, and is struck in the same place, the anterior fragment will tend to be strongly depressed, but the posterior will not be correspondingly elevated.

Control of Fragments.

As a general principle the fragments should be reduced to a normal position and a splint applied which will maintain them in that position. This is frequently possible in jaw fractures, but it is also frequently impossible; for instance, in fractures of the upper part of the ascending ramus, the condyle, and coronoid no form of splint will control the upper fragment, and it then becomes necessary to align the anterior fragment with the displaced posterior one. Also in severe comminutions it is impossible immediately to reduce all the fragments, since these are displaced in different directions by different muscles—reduction and control must proceed synchronously in these cases. Speaking generally, in order to effect control some appliance or surgical means should be adopted which will act in a contrary direction to the displacing forces. In this paper it is not proposed to discuss the simpler forms of fracture nor to enumerate the well-known types of splint. When teeth are present in both or all the fragments, control becomes a comparatively simple matter, but the classes of cases in which control becomes more difficult are: (*a*) those in which teeth are absent from one or both fragments; (*b*) severe comminutions, with involvement of the teeth.

But before passing to consider these conditions I should like to offer a criticism of two methods of temporary control at present being used. 1. The four-tail bandage as usually applied, with a pull almost directly backwards, only serves to exaggerate displacements already present. Fig. 1 shows how a four-tail may be used without doing much harm. 2. The Hammond splint fails to control upward and downward displacement of fragments, tends to increase the looseness of any already loose teeth, does not prevent the lateral tilting and swinging of fragments, and, moreover, requires as long a time and as much skill to apply as a more efficient splint.

The control of the posterior fragment, either when the fracture is posterior to the last molar or when the posterior fragment is edentulous, is always a matter requiring special treatment. When the posterior fragment is edentulous some form of saddle can usually be fitted to a metal cap splint.

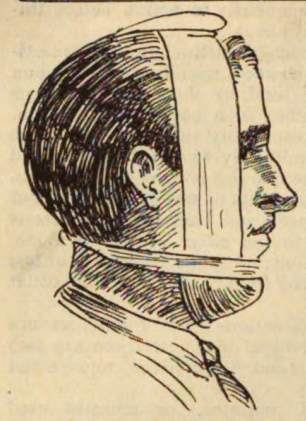

FIG. 1.—An improved method of applying the "four-tail." The vertical portion is broad and very tight, the horizontal being narrow and comparatively slack.

The saddle portion can either be rigid and reduction accomplished forcibly under an anæsthetic, or it may be attached by screws which will permit of a gradual reduction. When the fragment is just anterior to the masseter muscle and posterior to the last molar the control of the posterior fragment becomes somewhat difficult, since there is not sufficient horizontal ramus available to which a saddle can be attached. To overcome the difficulty I have devised two simple methods.

(*a*) When a suitable upper molar is available an *angle band* is fitted carrying an extension posteriorly which presses on the anterior border of the ascending ramus, and so prevents it being drawn forwards and upwards. (Fig. 2.)

(*b*) *The Zygomatic Screw.*—This is the most certain method of controlling any badly displaced posterior fragment. The posterior fragment is pulled down into position forcibly, preferably by forceps introduced through the wound, and is held in position by an assistant. An incision is made over

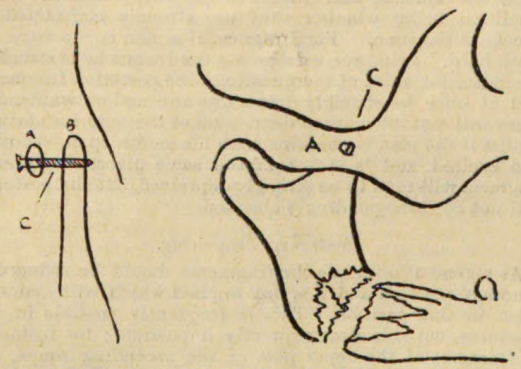

FIG. 3.—Left: Antero-posterior view (in section). Right: Lateral view. A, zygomatic arch. B, coronoid process of mandible. C, screw.

the zygoma, a hole is drilled through the latter and the coronoid process, and a long thin screw (¾ in.) is passed through both; if the other end impinges on the skull so much the better. No movement of the upper fragment is possible. In some individuals the coronoid process does not reach up under the zygoma; this does not very much matter, since then the screw is passed through the dense temporal fascia and muscle and effectually prevents movement. This method is very suitable for immobilising the posterior

fragments in bone grafts at the angle of the mandible. (Fig. 3.)

The Gutter-splint.—This is a modification of the Kingsley splint which I have used for some years chiefly as a temporary splint, but occasionally as a permanent one. It consists of a gutter shaped o the dental arch, capable of fitting over all the teeth if present, and filled with modelling composition.

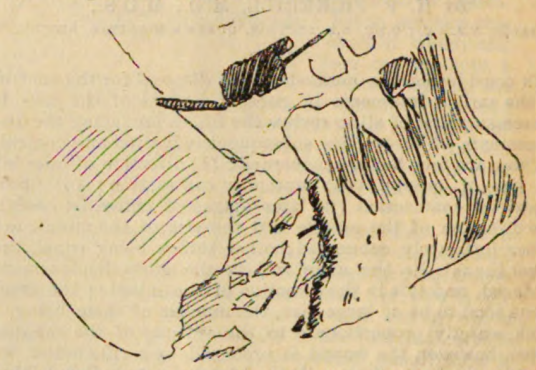

FIG. 2.—Extension from an "angle-band" posteriorly to control and prevent the upward displacement of a posterior fragment. (Tracing from skiagram.)

Attached to the metal gutter are two arms which project out of the mouth, and lie along the cheeks. The splints are made in three sizes and one is selected which approximately fits the case. (Fig. 4.) The displacement of the upper or lower jaw fragments are temporarily reduced by digital pressure, the composition warmed and the splint pressed into place, the arms being held in place by a bandage passing either above the head or below the

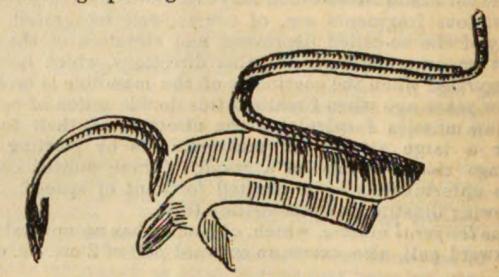

FIG. 4.—The gutter-splint. The groove or gutter is filled with dental modelling composition.

chin. A number of these were sent out with the New Zealand Expeditionary Force for use in the field, and if such temporary splints were more frequently used we should not get the exaggerated displacements and deformities which we sometimes see, and a considerable amount of pain would be saved to the patient and many secondary hæmorrhages avoided. I believe this is the most comfortable form of splint to use in the control of downward displacement of upper jaw fragments. Metal bands round the head are extremely uncomfortable and painful, and are, moreover, much more difficult to immobilise.

FIG. 6.—Bolt of stout wire passed through lower border of mandible to control symphysis fractures. The apparatus seen above is part of an external nasal splint. (Tracing from skiagram.)

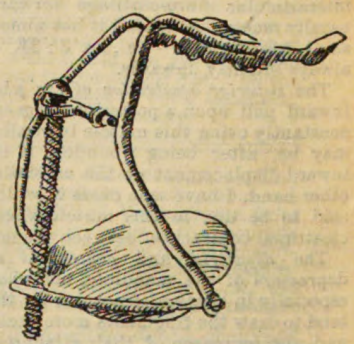

FIG. 7.—"Screw-lever" splint for controlling comminuted fractures in the anterior region.

Fractures of the neck of the condyle and *coronoid process* require special consideration. In these cases, since it is impossible to control the posterior or upper fragment, the

lower or anterior fragment must be placed in such a position as to secure good alignment and apposition. If displacement is due entirely to muscular force the coronoid will always be drawn upwards and outwards and the condyle upwards, forwards, and inwards (by the external pterygoid muscle). This must be determined, however, by skiagrams, since in aeroplane crashes, for instance, the displacing force of the crash may be much greater than the pull of the external pterygoid or the latter muscle may be avulsed.

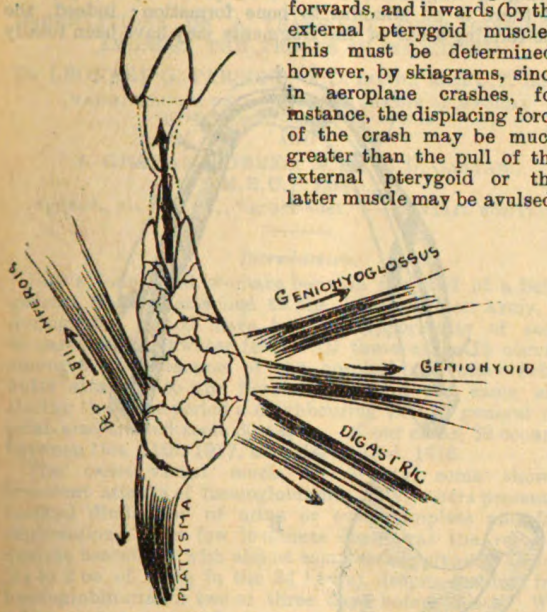

FIG. 8.—Diagrammatic view of action of muscles for comminuted fractures when the lower teeth are simply suspended to teeth in the upper jaw.

If the condyle is in the usual position the anterior part of the mandible should be brought into and secured in as high and forward a position as possible, at the same time bringing the chin a little towards the injured side. This is desirable because the upper fragment is displaced inwards by the external pterygoid muscle, and by rotating the chin slightly towards the injured side the fractured neck is made to move inwards. This may best be done, I think, by intermaxillary wiring, either by silver wires around the teeth, or if, as frequently happens, the upper jaw is edentulous, four holes are drilled, two in the upper and two in the lower jaw, at about the level of the roots of the incisor teeth, crossed silver wires are passed through, and the mandible thus laced up firmly to the maxilla in the desired position. The same method of control applies to fractured coronoid. (See Fig. 5.)

Fractures at the symphysis are sometimes liable to non-union. This is due to separation of the lower borders of the fragments owing to the outward pull of the elevator and depressor muscles, chiefly the digastrics. A dental metal-cap splint may be put on and the teeth brought together, but it is not observed whether the lower borders are at the same time approximated—rather do they naturally tend to be separated by the approximation of the teeth, and if, unfortunately, the teeth in the immediate fracture area are also extracted this approximation of the upper border and separation of the lower border tends all the more to occur.

I have endeavoured to eliminate this source of error by avoiding dental splints in this kind of deformity and using either intermaxillary wiring or by bolting the fragments together with a metal bolt passed through the lower border of the mandible posterior to the symphysis. (See Fig. 6.) This appeals to me as a rational method since it acts in a direction exactly opposite to the displacing forces, and moreover the teeth can be retained in situ, antiseptic treatment satisfactorily carried out, the jaw as a whole remaining functional.

The Control of Comminuted Fragments.

Before the war I believed, as the result of experience, that it was necessary to remove all small commiputed fragments and teeth in the vicinity of the fracture. In the great majority of gunshot wounds we are seeing to-day this is not necessary. The reason for the difference being, I think, that in civil practice fractured jaws frequently occur in unhealthy, cantankerous, and alcoholic individuals, whose resistance and reparative powers are not very high. The majority of our present patients are, however, extremely "fit," respond wonderfully to treatment, and one can retain fragments and adopt a much more conservative line of treatment than one could for civilians.

In comminuted fractures, however, there is frequently much displacement of small fragments owing chiefly to the unbalanced action of attached muscles. Especially is this so in the anterior region of the mandible. The teeth are much loosened and there are brought into existence numerous "dead spaces" around the fragments.

Upon the recognition of the necessity for the elimination of these "dead spaces" depends the successful conservative treatment of such cases. There is no reason why small fragments of bone or a tooth should not survive partial detachment and a certain amount of infection, provided they are relatively immobilised within reasonable time and not allowed to be more or less permanently bathed in pus.

If a simple dental splint is put on, the teeth are immobilised and not the fragments, with the result that the fragments are like floating islands in a sea of pus.

Believing this to be so, I some time ago devised a splint (Fig. 7) (which for want of a better name I call the "screw-lever" splint) and which I believe controls both teeth and fragments in comminuted fractures. It consists of a cap fitting over the retained teeth with arms passing out of the mouth and under the mandible; to the ends of these arms is hinged a padded lever which, by being depressed by a screw anteriorly, is raised in an upward and forward direction posteriorly.

In use the teeth are pressed downwards into their sockets, the fragments are pressed upwards, and are clamped between the cap and the pad with an increasing pressure; the teeth and fragments are both controlled and dead spaces eliminated.

A modification of this splint may be used for controlling depressed fragments at any point along the lower border of

FIG. 9.—Comminuted fracture. Lateral and anterior aspect of mandible. Treated by "screw-lever" method. (Tracing from a positive skiagram.)

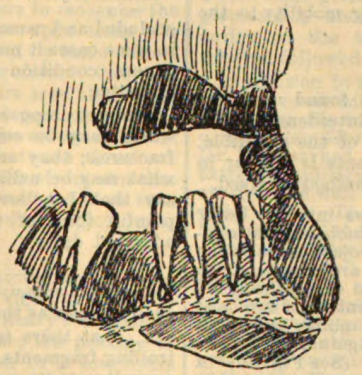

FIG. 10.—The same after use of screw-lever splint. Fragments reduced. Some rarefaction in central area. (Tracing from a negative skiagram.)

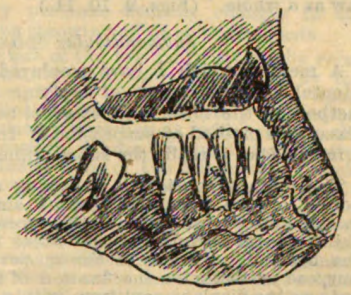

FIG. 11.—The same after removal of splints and normal use of jaw for a month. Consolidation is obviously taking place, and the teeth are in situ. (Tracing from a negative skiagram.)

the mandible. Care must always be taken, however, that the composition pads do not interfere with free drainage and irrigation.

An important asset which this means of control possesses is that the mandible remains functional and is not immobilised as a whole. Function is the best stimulus to bone production which we possess, and one which we might utilise much more fully. Also, I think we would do well to adopt Lucas-Championnière's teaching with regard to fractures—a principle which, so far as I am aware, has not yet been purposely applied to jaw fractures. I have two cases at the present time which illustrate this point in a remarkable manner.

The first is a patient who was awaiting bonegraft with a definite loss at the left angle, and had a double Gunning splint on for some months; something more than a month ago the site of loss was curetted, the screws taken out of the splint, and movement allowed. He is now getting a bridge of osseous tissue thrown out across the gap, and the patient himself says the jaw is as firm as ever it was, and that he can eat anything; the radiographic report is that union has taken place.

The second case is one admitted during the rush in the early part of April, with fracture in the right pre-molar region. Angle bands and expansion arch were put on as a temporary splint, and he was sent out to an auxiliary hospital. For some reason I did not see him for a fortnight, when it was found that the ligature wires to the arch had slipped, the posterior fragments was displaced outwards slightly, but that firm union was taking place. In less than a month firm osseous union was complete, despite the teeth in the fracture line on each side being retained.

Many teeth and fragments are sacrificed in the treatment of jaw injuries which might well be saved for the patient and obviate the subsequent supply and use of artificial dentures. The reason being, I think, that almost entirely "interdental" or suspensory types of splints are used. The lower jaw is simply suspended by means of its teeth to teeth in the upper jaw. The depressor muscles are being constantly used, in fact, they are the only ones used, the elevator muscles being thrown out of action by the splint, and consequently the jaw fragments are pulled downwards and backwards away from the suspended teeth with the frequent result of non-union, and the presence of the teeth is blamed for the result. (Fig. 8.) The extraction of the teeth frequently gives beneficial results by providing drainage, but I suggest that a more surgical procedure is to provide submental drainage and a form of splint which will clamp the upper and lower borders of the mandible, thus relatively immobilising the fragments whilst allowing mobility to the saw as a whole. (Figs. 9, 10, 11.)

Submandibular Splinting.

A method which I have employed and found useful in edentulous cases is that of applying the interdental splint method to the lower and external border of the mandible. Kasanjin's method of suspension of fragments is similar in principle, but is really the submandibular method reversed.

The method consists in inserting screws into the lower border of the mandible through small incisions in non-infected areas; the heads of the screws project through the skin an equal distance to that which they are screwed into the bone. The heads of the screws then serve the same purpose as teeth for the fixation of a splint. An assistant reduces the displacement from within the mouth and stout nickel-silver wires are bent round to fit against the screws and laced into position with ligature wire. (See Fig. 12.) A double vulcanite Gunning splint may be used as an additional support, but I do not regard it as satisfactory by itself in such cases, since it depends for its efficiency entirely on the tightness of a four-tailed bandage and does not therefore relatively immobilise the fragments; but it does effectively prevent function, whereas the submandibular screw method allows of normal function of the jaw as a whole.

In later stages when fractures have been neglected for some unavoidable reason, another factor, that of *fibro-cicatricial contraction* along the track of the original wound, tends to either produce fresh displacements or to exaggerate old ones.

There are two methods of dealing with this condition: (1) the immediate and surgical; (2) the gradual and mechanical. Of the two I think the first is always best when practicable. Time is saved by opening up the fracture-lines, removing the forming cicatrix, and freshening the bone-ends and wiring, or the immediate application of splints to a pre-determined position may be used. Fresh bone formation is thus stimulated. A similar result may be obtained by bending or stretching the cicatricial tissue connecting the fragments, but it is a comparatively slow process, and there is no stimulus to bone formation; indeed, the bone-forming areas of the fragments may have been totally occluded and osseous union may never occur. Nevertheless, in some cases it may be the wisest course when the patient's general condition and resistance does not warrant a severe operation.

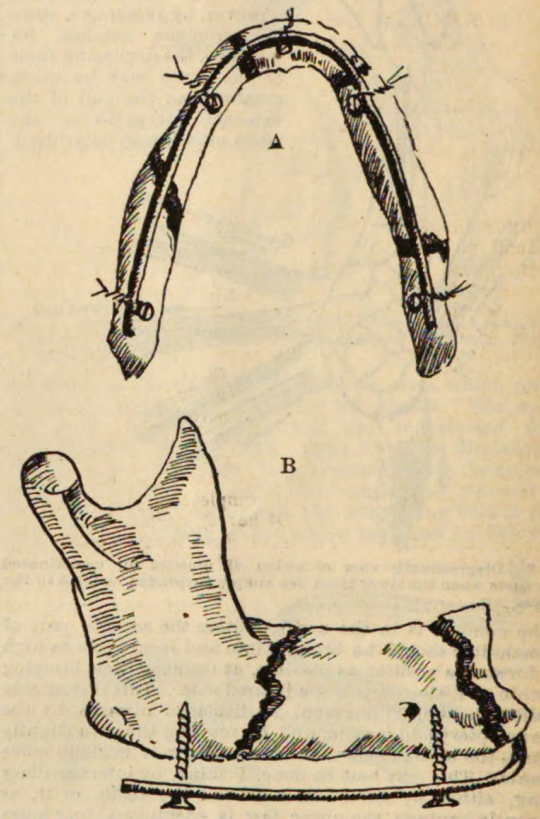

FIG. 12.—Method of submandibular splinting for small fragments in edentulous jaws. A, viewed from below. B, viewed from the side.

I do not propose to describe in detail any of the methods which may be employed for the gradual reduction of old fractures; they are sufficiently well known and are all of what may be called an "orthodontic" type. I would only say that I believe the most useful, powerful, and least painful form of traction is given by the use of screws adjusted daily.

Conclusions.

General principles.—If one may draw conclusions from such a paper as this, I would say:—

1. That there is, or should be, no best method of controlling fragments. Each case should be treated individually, according to its requirements.

2. Control and not absolute immobilisation of the fragments should be the aim of any method of treatment.

3. The utilisation of function and perhaps slight mobility of the fragments from as early a time as possible is the best stimulus to union.

4. A conservative line of control should be adopted whenever possible—i.e., loose teeth and small fragments should be retained and controlled with function rather than be sacrificed to obtain possibly a quick but inferior result. This is in accord, I think, with the trend of orthopædic surgery at the present time.

I have to thank Colonel W. H. Parkes, D.M.S., N.Z.E.F., for permission to publish this paper. Most of the methods described were evolved when I was in charge of the Jaw Department at No. 2 N.Z. General Hospital, Walton-on-Thames.

HÆMOGLOBINURIA (BLACKWATER FEVER).

OBSERVATIONS ON A TRANSIENT FORM OCCURRING AMONGST THE TROOPS IN MACEDONIA.

BY LEONARD G. PARSONS, M.D. LOND., M.R.C.P. LOND.,
MAJOR, R.A.M.C., T.F.; OFFICER IN CHARGE OF MEDICAL DIVISION, —— GENERAL HOSPITAL;
AND
J. GRAHAM FORBES, M.A., M.D. CANTAB., M.R.C.P. LOND.,
CAPTAIN, R.A.M.C., T.F.; PATHOLOGIST, —— GENERAL HOSPITAL.

Introduction.

SINCE June, 1916, we have been on the staff of a British general hospital attached to the Royal Serbian Army, and during that period have had the opportunity of seeing 46 cases of blackwater fever. Of these cases 13 occurred amongst the personnel of the hospital and other British units attached to the Serbian Army in the same area. During the same period a neighbouring British general hospital also treated some 30 cases. Of our cases, 38 occurred between Oct. 11th, 1917, and March 23rd, 1918.

The cases varied much in severity, some showing transient attacks of hæmoglobinuria only, others presenting marked diminution of urine or even complete and fatal suppression. In a few instances death was the result of uræmia associated with almost complete suppression of urine (1½ to 2 oz. of urine in the 24 hours), despite freedom from hæmoglobinuria for two or three days before death. With reference to amount of urine two clearly differentiated types of case were observed: 1. Those associated with polyuria which invariably recovered. 2. Those associated with diminution or suppression of the urine, some proving fatal.

The object of this paper is to draw particular attention to the cases showing a transient hæmoglobinuria. We regard the recognition of the danger of these cases as of prime importance for two reasons. 1. When hæmoglobinuria has once occurred a recurrence is very probable, and a transient case may subsequently develop a severe or even fatal attack. 2. Experience leads us to believe that all forms of blackwater fever will be more prevalent in the winter of 1918–19 than they were in the two preceding winters.

We have not been able to make any detailed study of the literature of the subject. Manson[1] appears to recognise the transient cases but does not lay stress upon them. A malarial hæmoglobinuria has been described by some writers and regarded as distinct from blackwater fever. Our view is that the transient cases we have seen are true blackwater fever in a mild form, and that, except in degree of severity, there is no difference between them and the severe and fatal forms of blackwater fever. All grades between these two extremes have been met with. We are also of opinion that the disease is not directly due to quinine, and we have seen no cases which could be regarded as quinine hæmoglobinuria.

Symptoms.

In these mild cases the symptoms observed are: nausea or vomiting, shivering, or even a definite rigor, followed by sweating; sometimes pain or a dragging, heavy sensation in the loins; usually some degree of jaundice; the passage of port wine or porter coloured urine, which in a few hours becomes normal in appearance.

These symptoms may be slight in degree or moderately severe, but are never as severe as in a sustained case of blackwater fever. They may be no more grave than those accompanying a mild malarial paroxysm, and but for the colour of the urine advice would very likely not be sought in many instances. Indeed, it is quite possible that the condition may be overlooked altogether. For instance, one patient (No. 0/553), convalescent from malaria, complained that he had passed black water during the night—a true statement—and also said that he had not had a rigor or feeling of cold, or even headache, backache, or sickness. His temperature had been 99·2°, and the night nurse reported that he had shivered and afterwards perspired freely. Such an example shows that the general symptoms may be trivial in nature or even absent.

Actual vomiting, also pain in the back and loins, are not common. The jaundice is variable in degree, but never severe, and is of the hæmolytic type. None of these cases have shown more than a moderate grade of fever; the highest temperature recorded was 103·2°; as a rule when the urine cleared the temperature became afebrile and remained so unless malarial recurrences occurred during convalescence.

The urine at the onset of an attack varies in colour from a reddish madeira to a deep port-wine shade which, in reflected light, appears almost black.

After being allowed to stand for a short time a light brown sediment is deposited, leaving the supernatant urine clear. The amount of deposit is usually considerably less than in the severer forms of blackwater fever. This appearance rapidly passes off, and after two or three specimens showing hæmoglobin colouration the succeeding urine looks normal to the naked eye.

Thus case No. 16,186 passed dark "port wine" urine for the first time in the afternoon; the next specimen, obtained during the night, although lighter in colour, still contained hæmoglobin; but the third specimen at 9 A.M. on the following morning was free from hæmoglobin.

The patient already mentioned (No. 0/553) passed three specimens of madeira-coloured urine between 1 A.M. and 8 A.M.; no more urine was passed until 4 P.M. the same day, and this contained no hæmoglobin.

In our series of cases there has never been any marked diminution in urine passed. In some cases a transient polyuria has been present; thus in the case just quoted 53 oz. were passed between 4 P.M. (the first normal specimen) and 8 A.M. the next morning.

Chemical and microscopical examination of the urine showed a remarkable sequence of changes.

The hæmoglobin, at first giving a very marked reaction, rapidly disappears. The amount of albumin, considerable in the first specimen, rapidly disappears in succeeding ones, but rather less rapidly than the hæmoglobin. Microscopically, the first specimen usually shows numerous casts—granular, hyaline, and epithelial—also many epithelial cells, in addition to a varying amount of granular amorphous debris, and occasionally a few red blood cells. These casts and epithelial cells rapidly disappear from the urine in succeeding specimens, as will be seen by a reference to the details of urinary findings. This sequence is so striking a feature of the transient form that, in a case admitted to hospital with a history of having passed black water, the rapid disappearance of casts and albumin from the urine may be taken as confirmatory evidence of recent hæmoglobinuria. Indeed, we are inclined to go further and say that, in this country, this sequence is sufficient to diagnose the occurrence of hæmoglobinuria even in the absence of any history of that symptom.

To explain this series of changes it would seem that the "toxin" of blackwater fever, (1) by its action on the red blood cells gives rise to hæmolysis with resulting hæmoglobinæmia and hæmoglobinuria, and (2) by its direct action on the kidney produces necrotic changes in the tubules, followed by the throwing off of epithelial casts.

In addition to the action of the toxin directly on the renal tissues, renal functions are profoundly influenced by the damaging effect of the passage of hæmoglobin and waste corpuscular debris. Both factors are probably responsible for the marked circulatory obstruction evidenced by the extreme capillary congestion. These tubular and congestive changes are well marked in some of the fatal cases of blackwater fever. The throwing off of the cast is the first step in the process of the repair of the kidney lesion.

In the transient cases we are describing, the "dose" of the toxin is a small one; repair begins at once, for casts are very obvious in the first specimen of black water passed. In the severer cases which recover casts are at first seldom seen or are seen only in small numbers; later they increase in number until they reach a maximum, when they may be present in enormous numbers, and then gradually diminish as the case improves, finally disappearing altogether. It is rare to find casts in cases which pass small amounts of urine and eventually prove fatal. The presence of large numbers of casts is therefore of much importance in prognosis.

Details of the urinary changes in three cases of transient hæmoglobinuria are given. Cases No. 16,186 and No. 0/553 have been referred to above. Case No. 0/551, a Greek doctor, was sent in by a French medical officer as a case of blackwater fever. He had passed black water from noon on the previous day until 10 A.M. on the day of admission. No hæmoglobinuria occurred afterwards but the urinary changes provided confirmatory evidence of his history.

Urinary Findings in Cases of Transient Hæmoglobinuria.

CASE NO. 16,186.—4/2/18, 3.30 P.M. Urine almost black, sp. gr. 1023, acid; albumin, +++; guaiac test, +++. Deposit: Casts, *many* granular and a few granular epithelial; cells, epithelium; R.B.C., none.

4-5/2/18, night. Urine red brown, sp. gr. 1020, acid; albumin, +++; guaiac test, +; casts *fewer* in number, same varieties; R.B.C., none.

5/2/18, 9 A.M. Urine, no naked-eye Hb, sp. gr. 1015, acid; albumin, +; guaiac test, 0; *no casts*; some pus cells: R.B.C., few.

[1] Manson: Tropical Diseases (sixth edition), p. 286.

CASE No. 0/553.—8/3/18, 1 to 5 A.M. Urine (clear) madeira, sp. gr. 1030, acid; albumin, +++; guaiac test, +++; bile pigment, 0. Deposit: Few granular and fine hyaline casts; some renal epithelial cells and leucocytes; R.B.C., none.
8/3/18, 4 P.M. Urine, no naked-eye Hb, sp. gr. 1010, acid; albumin, slight cloud; guaiac test, 0; casts, none; few renal epithelial cells and leucocytes; R.B.C., none.
4 P.M. to 8 A.M., 8/3/18–9/3/18. Urine normal, sp. gr. 1018, acid; albumin, slight cloud; guaiac test, 0; some granular casts; renal epithelial cells.
14/3/18. Urine normal, sp. gr. 1030, acid; albumin, 0; guaiac test, 0; no casts; no cells; no R.B.C.; amorphous urates.

CASE No. 0/551.—23/2/18 (on admission). Urine yellow orange, sp. gr. 1020, acid; albumin, ++; guaiac test, 0; bile pigment, 0. Deposit: Casts *abundant*, granular, hyaline, epithelial; *many* renal epithelial cells and leucocytes; R.B.C., very few; mucus.
25/2/18. Urine normal, sp. gr. 1012, acid; albumin, +; guaiac test, 0; casts, *some* granular and hyaline, *few* degenerated epithelial; *scanty* leucocytes and renal epithelial cells.
28/2/18. Urine normal, sp. gr. 1010, acid; albumin, very faint haze; guaiac test, 0; casts, *few* hyaline and finely granular; cluster or two of leucocytes; R.B.C., none; cell debris.

Albumin. +++, heavy deposit. ++, dense cloud. +, definite cloud.
Guaiac test. +++, very marked reaction. ++, marked reaction. +, definite reaction.

Associated with hæmoglobinuria and the symptoms already mentioned, the spleen is found to enlarge and not infrequently become tender. In some cases the liver also enlarges, and there may be tenderness over the gall-bladder region. All these signs disappear shortly after the hæmoglobinuria stops.

Convalescence, if not complicated by malarial relapses, is, as a rule, rapid and not much more prolonged than after an attack of malaria. A certain degree of anæmia occurs, but it is not marked. In most of the cases, however, convalescence was retarded by malarial relapses, but without further hæmoglobinuria.

Etiology.

In the present paper we shall only deal with certain points in connexion with this series of cases, but the remarks apply also to blackwater fever in general.

(*a*) *Associated with other diseases.*—Every case gave a history of repeated attacks of malaria, and many suffered from malarial relapses whilst in hospital.

Some were under treatment for, or convalescent from, malaria at time of onset of hæmoglobinuria. No case of blackwater fever has been seen in association with any other disease, with two possible exceptions, which were at the time under treatment for dysentery and malaria. (One of these occurred in the present series—viz., Case No. 16,816.) Examination of the blood for malarial parasites was usually negative. Of the 9 cases of this variety of blackwater subtertian parasites were present in one case only; another case showed scanty parasites of uncertain type, probably benign tertian. In the remainder no parasites could be found. One of the negative cases, however, showed hæmozoin pigment in the leucocytes, and benign tertian parasites were found in the blood in a malarial relapse (February, 1918) during convalescence.

(*b*) *Length of time exposed to malarial infection before hæmoglobinuria occurred.*—We are informed that malaria is not a common disease in Serbia, and that it is of a mild type.

A large proportion of malarial patients admitted to the hospitals attached to the Royal Serbian Army contracted the disease in the summer of 1916, when the re-equipped Serbian Army, recently landed from Corfu, was encamped in the neighbourhood of Salonika. The army took its place in the line early in August, 1916, and at that time there were many cases of malaria. All the transient cases and all except 8 of the more severe forms of hæmoglobinuria occurred in the winter of 1917–18, and it may therefore be assumed with a considerable degree of certainty that the Serbian cases had not passed through more than two severe malarial seasons. One of the transient cases occurred amongst the British troops attached to the Serbian Army, and he came out to Macedonia in June, 1917, and was therefore exposed to one malarial season only.

These two facts—namely, that all except 8 out of the 46 cases of blackwater fever occurred during the 1917–18 winter and that no transient cases occurred before this winter—we consider, justify our opinion (1) that an increase in blackwater fever amongst the troops in Macedonia may be expected in the 1918–19 winter; and (2) that a definite number of cases of transient hæmoglobinuria, precursors of the more severe attacks, have already very probably escaped, and may in the future escape observation. The increase of liability to blackwater fever associated with and, in all probability, favoured by continuous periods of residence in a malarious and blackwater fever country has been frequently noticed, and is now well recognised.

(*c*) *Topography, weather, &c.*—The cases were derived from one sector of the Serbian front, which occupies a position in a wide valley leading from the plain up to the mountains where the trenches were situated.

In both plain and valley malaria of a severe type is very rife. The incidence of the disease reaches its maximum during the five or six weeks between the middle of September and the end of October. The incidence curve of blackwater fever, on the other hand, did not begin to rise until October, reached its maximum in February, then fell quickly, and after April and throughout the summer kept very low. Most of the cases occurred during the colder part of the year, and there is no doubt that the condition, as in malaria, may be precipitated and aggravated by exposure to cold and fatigue. The influence of these factors is supported by the well-known effect of cold in producing an attack of hæmoglobinuria in cases of paroxysmal hæmoglobinuria. In many instances cold could certainly not be excluded, because falls of snow and hard frosts were frequent in the trenches during these months. In more than one case, however, this factor could apparently be discounted because the attack occurred in quite warm weather, such as was experienced at times during the winter months of 1917–18, and amongst individuals living in the plain and not in the mountains.

(*d*) *Presence of a specific hæmolysin, &c.*—A certain number of experiments have been carried out by one of us (L. G. P.) to determine, if possible, the presence of a specific hæmolysin.

The difficulties in demonstrating a specific lysin are great; it is highly probable that by the time the hæmoglobin appears in the urine the lysin has done its work and disappeared from the blood. This would seem to be so particularly in the transient forms of hæmoglobinuria, and even in those cases which show a naked-eye hæmoglobinæmia at the time of the experiment the same may be true. Hæmolysis is, of course, taking place coincidently with the rigor, vomiting, and raised temperature; and if the serum were taken at this early period better results might be obtained; these symptoms, however, frequently occur before the patient comes into hospital or are thought to be the onset of an ordinary malarial attack. Up to the present we have not been successful in obtaining blood serum in the initial stage of an attack, and we have not obtained any evidence of a specific lysin.

The sera have been tested against the washed red blood cells of individuals in hospital for other conditions than blackwater fever, and control experiments have also been done by putting sera of normal individuals up against the washed red blood cells from cases of blackwater fever.

As a rule a 10 per cent. dilution of sera and 10 per cent. dilution of red cells were used, but in a few cases undiluted sera were also tried against a 10 per cent. dilution of red cells. The hæmolytic tubes containing sera and cells were put into the incubator at 37° C. for one hour, being shaken about every 10 minutes; afterwards they stood outside the incubator for 12 hours. As we had no ice-chest this was timed so that the tubes were outside the incubator all night, for the nights were frosty. The sera of blackwater fever patients were also tested against the citrated blood of these normal individuals in order to see if agglutination of the red cells took place. Sufficient serum and cells for these tests can be obtained from 1 c.cm. of blood; this amount of blood can be easily removed from the patient's vein with a hypodermic syringe and needle without doing the least harm to the worst case of blackwater fever.

The sera of five of the transient cases were tested in this manner.

In two cases only was there even the slightest degree of hæmolysis and in each of these the tinge of hæmolysis occurred with one group of normal cells only. It is perhaps noteworthy that these two blackwater sera showed marked agglutination of the red cells when tested against the citrated blood from which this group of cells was obtained.

Marked agglutination occurred in some of the other experiments, but no hæmolysis.

A rather interesting result was obtained in another case. The point has probably been already observed, but it throws a little light on the changes occurring in blackwater fever. The specimen of urine passed by the patient (No. 0/553 before the blood was taken contained hæmoglobin; the next specimen passed some hours later was free from hæmoglobin, but the blood serum showed most definite tinting with hæmoglobin (hæmoglobinæmia). The hæmoglobin free in the blood-stream had probably been dealt with by the liver and it was noted subsequently that the stools apparently contained an excess of bile pigment.

The fragility of the red cells in some of these cases was tested against varying percentages of saline and found to be normal. It is universally agreed, we believe, that the "fault" in blackwater fever does not lie with the red cells.

(*e*) *Relation between quinine and hæmoglobinuria.*—We have formed the opinion that quinine is not *the* cause of hæmoglobinuria.

We have seen cases where quinine had not been taken for weeks previous to the appearance of blackwater fever. Patients have been given quinine during the attack and no untoward results have occurred; moreover, several of the cases have shown typical malarial attacks during convalescence and have been treated with quinine in doses up to 70 gr. per diem without a return of blackwater. Outside our own experience, however, there would appear to be some evidence that quinine may in very rare instances act as the determining agent in precipitating an attack of blackwater fever comparable, as already suggested, to the effect of exposure to cold, over-exertion, and fatigue. We are of opinion, however, that the possible existence of such cases should not influence treatment, for, even if they do exist, they are extremely rare.

We tried the effect of adding red blood cells from cases of blackwater fever to solutions of common salt in strengths of 0·05 to 0·9 per cent., in each of which was dissolved quinine bihydrochloride in strengths which we estimated would represent the concentration of quinine in the blood when administered by the intravenous method in doses of 10 to 15 gr. It was found that in some cases hæmolysis did not occur with strengths above 0·3 per cent.—i.e., the normal limit, but in other cases hæmolysis occurred with all strengths up to 0·9 per cent. It was therefore thought possible to separate out two classes of blackwater fever—namely, those in which quinine could be given, and those in which its action would be harmful, and that in this way the test would prove an important guide to treatment. Later, however, we obtained similar results in patients not suffering from blackwater and actually taking quinine at the time. It was also found that in cases of hæmoglobinuria whose red cells showed hæmolysis in all strengths of the solution, the quinine given caused no increase in the amount of hæmoglobinuria, and that after an attack had passed off subsequent administration of the drug did not produce a recurrence.

In concluding our observations on etiology, we would add our belief that blackwater fever is due to malaria, although not necessarily associated, at the time of its occurrence, with a malarial paroxysm, and that the true causal factor of the blackwater fever attack must be looked for in connexion with the toxins of the malarial parasite.

Certain work has been done on the malarial toxins, but there still remains a considerable field for research into their nature. The suggestion that the hæmolysis is due to supersensitisation of the red blood cells does not, in our opinion, give a satisfactory explanation of the fatty degeneration of the myocardium and the necrotic changes found in the liver and spleen in fatal cases. Nor does this theory explain the very marked degenerative and tubal changes or the extreme congestive disturbances which occur in the kidney in such cases. We consider the uræmia and anuria are due to these renal changes rather than, as is usually held, to the mechanical effect of the blocking of the tubules with hæmoglobin.

Further, these changes much resemble those found in other severe toxic conditions—e.g., eclampsia—and afford strong presumptive evidence of the presence of a toxin in the blood. This toxin apparently differs from the ordinary malarial toxin, since in deaths from malaria the spleen, liver, and particularly the kidneys, do not show the striking changes seen in blackwater fever. Certain facts appear to point to this special toxin being elaborated in the intervals between malarial attacks, for hæmoglobinuria frequently occurs unaccompanied by any actual malarial paroxysm.

Treatment.

All our patients were treated at the commencement of their illness as if suffering from severe blackwater fever, but when it was seen that the case was a transient one treatment was modified accordingly.

Warmth, absolute rest in bed, administration of a saline aperient, and copious drinks of lemon water, barley-water, soda-water, &c., were ordered. The only food allowed was milk, and patients were encouraged to take at least 5 pints of fluid in the 20 hours; some, indeed, drank as much as 8 pints in that period. Some of the cases received rectal salines, 5 oz. of normal saline being given every two hours, or 10 oz. every four hours. These were, however, stopped in the course of a few hours when it became obvious that the case was a transient one.

At the end of 48 hours the strict milk dietary was relaxed, and milk pudding, bread-and-milk, jelly, &c., were allowed. The diet was further increased *pari passu* with the improvement in the urinary symptoms, which usually cleared up so rapidly that the patient soon reached a full diet.

Quinine was given, not as a routine measure, but only if evidence of active malarial infection was shown, either by finding parasites in the blood or by the development of malarial symptoms following on, or in addition to, the hæmoglobinuria.

When quinine is necessary it is, perhaps, best administered intramuscularly, but it has also been given by the mouth or, occasionally, by the rectum, 5 gr. being added to each rectal saline. Quinine sulphate has been given by the mouth and the bihydrochloride by the two other methods.

Quinine amblyopia is stated to be more common in blackwater fever than in malaria, and therefore it has been recommended that great care be taken in determining the dosage of quinine in this disease; whilst not disputing this point, we think that some of the visual symptoms may have been due to retinal hæmorrhages, such as have been observed in certain of our cases by our colleague, Captain W. Niccol, R.A.M.C., ophthalmic specialist to the hospital. During the hæmoglobinuria we have not given more than 45 gr. in the 24 hours, but in the relapses of convalescence we have given 60 gr. daily, and in one case of a severe relapse 70 gr. a day were given on two successive days.

During convalescence a generous diet was ordered and iron and arsenic given.

Convalescent treatment was continued for a longer period than for an ordinary malarial attack. The period of absolute rest in bed should be about ten days; some of our cases, however, were up before that length of time had expired, because it is almost impossible to keep a Serb patient in bed when he is feeling anything approaching well.

As previously stated, malarial relapses occurred during convalescence in nearly all the cases and were treated as ordinary malarial attacks.

A careful watch should be kept on the urine during these relapses on account of the possible recurrence of hæmoglobinuria. All cases after recovery from an attack should be removed from a blackwater fever area, and, if possible, evacuated from Macedonia owing to the risk of recurring and more severe attacks of blackwater fever.

Prognosis.

The prognosis of the actual attack of transient hæmoglobinuria is invariably good; indeed, as stated above, the symptoms may be quite trivial, and most cases would recover even if no treatment were received. The outlook, however, may be grave in a patient already seriously debilitated by previous malaria or dysentery. In the only case in our series which gave us any anxiety there was marked debility from recent malaria and dysentery at the time the hæmoglobinuria occurred; after three days, however, the patient made a rapid improvement and was soon out of danger.

As for their future prognosis, we believe that these cases are liable to recurrences of hæmoglobinuria, especially if they remain exposed to malarial infection. Moreover, in all probability these recurrences will prove more severe than the original attack. Judging from the cases we have seen, no permanent damage is done to the kidneys by these transient attacks.

Conclusions.

This paper has been written to draw particular attention to these cases of transient hæmoglobinuria for the following reasons:—

1. The condition is frequently a slight one and may escape notice unless looked for; but apart from its mild character it is in all respects the same disease as blackwater fever and should so be regarded. All varieties, including intermediate cases between the transient and the severe and fatal forms of blackwater fever, have been seen.

2. Transient hæmoglobinuria is very likely to be the precursor of more severe recurrences.

3. It is highly probable that the transient cases and all other forms of blackwater fever will be more common among the troops in Macedonia during the winter months of 1918–19 than in previous winters.

Finally, our thanks are due to Colonel S. F. Clark, A.M.S., the officer commanding the hospital, for allowing us to make use of these cases; also to our colleagues, Captains H. C. Nickson and C. G. Teall in particular, for their help in the diagnosis and treatment.

Macedonia, May, 1918.

OUTBREAK OF TYPHOID FEVER IN TORRY, ABERDEEN.—For the last three weeks the notifications of typhoid fever from Torry, Aberdeen, have been 15, 28, and 12. Dr. Matthew Hay, medical officer of health for Aberdeen, states in last week's report that it is now practically certain that many of the cases are traceable to an infected milk-supply.

A NOTE ON

THE SUSCEPTIBILITY OF THE ANTI-SCORBUTIC PRINCIPLE TO ALKALINITY.

BY A. HARDEN, D.SC., F.R.S.,
PROFESSOR OF BIOCHEMISTRY IN LONDON UNIVERSITY;
AND
S. S. ZILVA, M.SC., PH.D.
(*From the Biochemical Department of the Lister Institute.*)

THE main sources for the supply of our antiscorbutic requirements are certain vegetables and fruits, most of which are cooked before they are eaten, although a certain proportion is consumed raw, especially in the summer. In the winter very little, if any, fresh uncooked vegetable is eaten in this country, but unpreserved raw fruit is usually within the reach of most. During the forthcoming winter, however, owing to the unsatisfactory fruit crops, it may be anticipated that the main source of antiscorbutics in our diet will be found in cooked vegetables, thus leaving us dependent on a rather less profuse supply of this dietary essential than is customary in normal times. Without anticipating any alarming consequences, it will nevertheless be advisable to bear this point in mind.

The object of this note is to describe a few experiments that form a part of an inquiry in which we are now engaged, which reveals a fact, in our opinion, of practical as well as of theoretical significance. The observation in question discloses the extreme susceptibility of the antiscorbutic factor to alkalies.

The most convenient way of testing the antiscorbutic potency of a substance is on guinea-pigs. These animals, as is well known, if kept on a diet of oats, bran, and autoclaved milk, succumb to scurvy within a period of 3–4 weeks. Any antiscorbutically active substance given in addition to this scorbutic diet will either delay or prevent the onset of scurvy, according to the potency of the dose. It is found that a daily addendum of 3–5 c.cm. of freshly expressed orange juice keeps a guinea-pig in good condition.

In our first experiment we administered daily doses of 3, 5, and 7 c.cm. of orange juice made neutral to phenolphthalein respectively to three guinea-pigs, which were kept on a scorbutic diet. All these animals throve well for 78 days, gaining in weight. At the end of that period they were chloroformed, and at the post-mortem examination no scurvy was observed. When, however, the orange juice was made N/20 alkaline with NaOH and stored for 24 hours in the cold room before administration daily doses of 3, 5, and 7 c.cm. did not prevent or delay the onset of scurvy. This result is not due to the effect of the alkali on the animals, for when the N/20 alkaline orange juice, after having been stored for 24 hours, was made N/20 acid with HCl before being given to the animals the effect still persisted. In this instance, as in the previous experiment, daily doses of 3, 5, and 7 c.cm. did not prevent or delay the onset of scurvy.

A much less drastic treatment was also found to be fatal to the antiscorbutic factor. Another set of three pigs received daily 3, 5, and 7 c.cm. of orange juice made only N/50 alkaline with NaOH on the day of feeding. All the animals died of scurvy after a slightly prolonged period, thus showing that the juice, after being made alkaline, retained only a trace of its antiscorbutic activity.

These experiments show definitely that alkalinity has a very deleterious effect on the antiscorbutic potency of orange juice. Theoretically this observation invites further investigations; but, as we have already pointed out, in view of the present food position it is of some practical importance. Most antiscorbutic vegetables are either neutral or very slightly acid, and any culinary manipulation which entails alkaline treatment, even to a slight degree, will be instrumental in the destruction, if not of the entire, at least of a significant part of the antiscorbutic potency of such vegetables. At a time when our need for antiscorbutics will have to be satisfied only by the consumption of cooked vegetables this becomes a problem of importance, and an immediate elucidation of the matter to the lay public becomes very desirable. At any rate, the point merits the attention of those interested in dietetics.

THE PROGNOSIS IN "TRENCH" NEPHRITIS.

BY S. C. DYKE, M.B., B.CH. OXON.,
CAPTAIN, R.A.M.C.

ALTHOUGH a number of reports have been published upon the clinical course of that particular form of renal disorder so rife among the British Armies in France and usually known as "trench" nephritis, there are up to the present comparatively few observations upon the later progress of these cases. With a view to throwing some light upon the prognosis in this condition an attempt is made below to analyse the after-history of 50 of these patients up to periods of within 12 months from the onset of acute symptoms. The 50 cases form part of a series of 100 upon which clinical observations were made at a base hospital in France in the early months of 1917. It has been made possible to follow their course through the home hospitals and disposition by means of the scheme devised by the National Research Committee. At a later date it is hoped that a fuller report, showing the final condition of all the 100 cases, may be made possible through the same means.

Analysis of After-histories.

Mortality.—One death only is reported in this series of 50. The cause of death in this case was scarlet fever, which developed two weeks after admission to a home hospital and a month from onset of nephritis. Fatal on 25th day from appearance of rash. This case was one of the mildest in the series. Œdema had disappeared by end of first week, and albumin from urine by eleventh day. At time of appearance of scarlet fever patient was convalescent. No P.M.; no record of condition of kidneys at death. No statement as to actual cause of death, whether from renal complications or otherwise, accompanied schedule of case.

The nephritis here, although it may have rendered the patient more than usually susceptible to the action of the scarlet fever toxins, cannot be regarded as the actual cause of death.

The prognosis with regard to life is very good.

Degree of recovery.—The schedules of the remaining 49 patients show their histories up to periods from the middle of the second to the end of the ninth month from the onset of the nephritic symptoms. They were universally filled in by the medical officers of the home hospitals, either on the actual settlement of the disposition of the patient or at a period in the history of the case when, although not actually made, it was evident what it would be.

Of the 49 cases, 23 are reported as having been discharged to the Command Depôt as fit for service. Six more are stated to have been transferred to homes or minor hospitals for the completion of convalescence, with every prospect that they also would become fit for the Command Depôt. In all these cases the recovery may be regarded as having been complete, and they will hereafter be referred to as "fit." That is to say, 29 out of 49, or approximately 60 per cent., of the patients made a return to complete health.

The prognosis as to perfect restoration to health is fair.

Of the remaining 20 cases, 11 were invalided from the Army, 4 were still undergoing treatment in hospital with no prospect of their ever regaining perfect health, and 5 had been classed C III. and sent to "employments." These will hereafter be all classed together and referred to as "unfit." In 40 per cent. of the series, then, the re-establishment of function was incomplete, and although not entirely destroyed the health of the patients was permanently damaged.

Influence of age on prognosis.—

In the clinical report on the original 100 cases[1] it was pointed out that the incidence in regard to age is spread with a rather striking evenness over the five-yearly periods between 20 and 40. The vast majority of the British soldiers in France fall between these ages, and it is not surprising that only one case occurred below 20, the age of this patient being 19. Considering, however, how comparatively few men of 41 or over were in 1916 on active service in France, it is rather suggestive that 8 per cent. of the cases fall into this category. The ages of incidence for the remaining 91 cases were as follows:—

Age 20 to 25	23 cases.	Age 31 to 35	23 cases.
,, 26 to 30	21 ,,	,, 36 to 40	24 ,,

[1] Clinical Observations on 100 Cases of "Trench" Nephritis, Captain S. C. Dyke, R.A.M.C., Journal of the Royal Army Medical Corps, February, 1918.

There are probably considerably more men in the British Expeditionary Force in France between the ages of 20 and 30 than between 31 and 40, and it is certainly worthy of note that the number of cases in the former group was only 44, as compared with 47 between the latter ages. There are, moreover, certainly fewer men in the field between 36 and 40 than between 20 and 25, and the fact that the figures for these two series are almost identical—24 as compared with 23—points to the same conclusion—namely, that the liability to the malady increases with age.

A further examination of the after-histories indicates that age is also an important factor in the prognosis. A consideration of the accompanying table will make this evident:—

		Age over 35.	Age under 35.
Becoming fit	29	4	25
Not becoming fit	20	11 (73%)	9 (27%)

In the fit class only 2 patients occur of the age of 40 or over, and only 4 of 35 or over, and this despite that in it are contained 60 per cent. of the whole series. Of those patients who failed to become entirely fit 6 were over 40 and 11, or over 50 per cent., were over 35 years of age. Of 15 patients over 35 years of age 11, or 73 per cent., failed to become fit; of 34 patients under that age only 9, or about 27 per cent., failed to regain complete health.

The rough conclusion may be drawn that, whereas in persons under the age of 35 suffering from this condition the probabilities are strongly in favour of complete restoration to health, in those of over 35 the likelihood is that permanent damage will remain.

The prognosis becomes worse with increase in age.

Resulting disabilities.—Of the 20 cases returned as unfit or likely to become so the reasons for the decision as given by the medical officers filling in the schedules were as follows:—

Albuminuria persisting from second to sixth month in 8 cases.

Chronic nephritis, further specified as interstitial in 2 cases and as parenchymatous in 1 case. In all 7 cases.

Arterio-sclerosis, 2 cases.

Anæmia, once accompanied by "backache" and once by œdema in 2 cases.

One patient was transferred to class C 3 on account of his age, 42. This man gave a history of an attack one year previously.

Arterio-Sclerosis.—

Although arterio-sclerosis was given as the reason of unfitness in only 2 cases its presence was observed in the peripheral circulatory system of 8 out of the 20 patients failing to make a complete recovery: in one other signs of this condition were noted in the retinal vessels only, making a total of 9 in which the arteries were obviously affected. In one further case a systolic bruit is recorded as the only abnormal feature in the cardio-vascular system. In 6 arterial changes are definitely stated as not to have been found, while in 4 no observations were recorded on this point. Thus of the patients who failed to do well 9 showed definite signs of arterial degeneration, in 7 such signs were absent, in 4 they were not looked for.

Arterio-sclerosis is present in about 50 per cent. of patients not entirely restored to health.

Of the 29 patients returned as fit for service observations were made as to the state of the cardio-vascular system in all except one, and in only one is any morbid change recorded. This consisted in a slightly accentuated second sound and some thickening of the radial artery. It occurred in a patient in whom a cloud of albumin was still present in the ninth month. The schedule was not very definite as to the patient's disposition, and it is possible that he was actually returned as unfit after it had been completed and had left the medical officer's hands. In 80 per cent. of the cases, then, there was no appearance of signs of arterial degeneration during convalescence.

Arterio-sclerosis is not a common immediate result of the condition.

The arterial changes referred to are reported as appearing from the third to the ninth month from onset.

Eye changes.—Examination was made for eye changes by the medical officers having charge of the cases in the home hospitals in about half of the series.

In only 6 were definite changes recorded, and these all belong to the unfit category. Of the changes, tortuosity of the retinal vessels with high reflex from the arteries and other signs of arterio-sclerosis were recorded four times, choroidal hæmorrhages twice, pallor of the disc twice, hyperæmia of the disc twice, "Tay's choroiditis" once. In no case was there any marked departure from normal vision.

Other factors in prognosis.—Search through the past histories of the patients who failed to make a good recovery revealed the fact that 3 of them had had definite attacks of renal trouble in the past. As these were the only patients in the series of 50 giving such a history it is striking to find them all in the minority of cases which failed to do well.

Of the 9 patients under the age of 35 who failed to make a complete recovery, and whose failure so to do cannot therefore be attributed to changes in the kidney associated with age, 2 gave a past history of acute rheumatism and 3 of acute pulmonary conditions in the past. One gave a history of "backache," which might or might not have been a renal symptom. Two of the remainder were clinically very severe cases from the onset. The remaining one was clinically a mild case at the onset, and it was with surprise that it was found on receiving his after-history sheet that he had been invalided from the Army in the ninth month, albumin being still present in the urine, as suffering from "chronic nephritis." Unfortunately, syphilis was not excluded in any of these cases.

Œdema and prognosis.—The œdema had disappeared in the majority of cases before the patients were sent to England, but in a few it was still persisting at the time of transfer to the home hospitals. By means of the after-history schedules it has been possible to form some idea of the relationship between the persistence of the œdema and the prognosis.

In every case except 1 the œdema disappeared before the albuminuria. The periods of its disappearance were as follows:—

Before end of first week	23 cases.	From second week to end of first month ...	10 cases.
During second week ...	6 ,,	During second month	7 ,,

It was still present after the end of the second month in 4 cases.

Of the 39 cases in which it disappeared before the end of the first month 28 became fit; of those in whom it persisted after the first month only 1 became fit. In this case the œdema disappeared finally on the forty-fifth day, and this was the only case in which it is reported as persisting after the albuminuria.

From the above it is concluded that:—

1. The œdema usually disappears during the first week. Its persistence during the second week is common; its persistence after the second week renders the prognosis increasingly unfavourable.

2. The presence of œdema after the end of the first month indicates that restoration to health will be incomplete.

Albuminuria and prognosis.—Practically all the patients were sent to England still showing albumin in varying quantities in their urine. Its disappearance was recorded on the schedules in 32 out of the 50 cases. From the time of onset the dates of its disappearance were as follows:—

Before end of first week	0 cases.	During second month ...	12 cases.
During second week ...	2 ,,	During third month ...	5 ,,
From second week to end of first month	7 ,,	During fourth month ...	2 ,,

Total before end of fourth month, 28 cases.

Of the above 28 cases, only 2 fall into the unfit class. Of the remaining 22 cases, it disappeared during the fifth and sixth month in 4 cases, but of these 2 were reported as permanently unfit. It was still present at the time of making the report in 18 cases, of whom 16 had been invalided out of the Army or classed C 3.

The above figures seem to show that—

1. The albuminuria usually ceases towards the end of the first or during the second month.

2. It may persist during the third month and the case still end favourably.

3. Its continuance after the end of the third month from onset renders the prognosis as regards restoration to complete health unfavourable.

Note on Etiology.

Although in collecting the facts for the original clinical report it had been hoped that some light might be thrown on the etiology, this hope has hardly been justified. Only two positive deductions bearing on the question could be made.

1. That the condition is proportionately commoner among troops the greater the exposure their work entails.

2. That the liability to the condition increases with age.

Among suggestions as to the causation of this condition made in the past have been (1) the presence of chloride of lime in the drinking water; (2) the absence of vitamines from the rations; (3) poisoning by heavy metals ingested in

solution in the juice of tinned fruits; (4) the action of poisonous gases; (5) that it is due to an infection.

In regard to suggestions 1 and 4 it is sufficient to point out that this condition was common in the Federal Army during the American Civil War, when in the Wilderness that Army was fighting under conditions of exposure and hardship similar to those now imposed upon the men on the Western front. But the Federal troops were strangers to both chloride of lime in their drinking water and poisonous gases in their trenches. Moreover, if poisoning by gas plays any part in this condition, the great increase in the use of gas shells, dating from the end of 1916, should have been followed by a corresponding rise in incidence, and this has not been the case.

As to the absence of vitamines, it is sufficient to point out that at the period under consideration preserved food formed only a small part of the rations, and there was no reason to suspect any shortage of these bodies.

If the consumption of tinned fruit has anything to do with causing the condition it ought to be proportionately more common among the officers than among the men, for much more tinned fruit is eaten in officers' messes than among the men. The fact is that the reverse is the case.

In pursuance of the view that the condition is of infective origin, various organisms have been isolated from the urines or nephritic cases, and in some instances vaccines prepared from them have been used in treatment. Recovery followed, but this is only surprising to those who disbelieve in vaccine therapy. Tytler and Ryle[2] recovered a streptococcus forming greenish colonies on blood agar from nephritic urine; they recovered similar organisms from controls, but in a smaller proportion of cases. They do not appear to attach much importance to this organism as an etiological possibility. Davies and Weldon[3] state that they have known instances of transmission of the disease to attendants, but the details given are so scanty that they can hardly be intended to serve as evidence.

There is one factor or group of factors common to all cases occurring in the B.E.F. in France and to the outbreak during the American Civil War, and that common factor is excessive and prolonged fatigue in combination with exposure.

It has long been recognised that albumin, often in large amounts, and casts are almost constantly present in the urine of healthy adults after such exertion as is entailed by ordinary athletics. This albuminuria is stated always to clear up and to leave no ill-results or predisposition to renal trouble. Such is undoubtedly the case in athletes, who after the game is over can take as much rest as they please. Among soldiers under modern war conditions, however, the case is very different. The battle does not stop like a game; it continues for days, weeks, or months, and the soldier must participate until his unit is relieved. When not actually attacking or repulsing attacks, the soldier is engaged in digging, ration-carrying, wiring, or some other arduous work. His intervals for sleep are inadequate and short, and his rest is uncomfortable and broken. Under such circumstances it is conceivable that what in the athlete may be a passing symptom, may in the soldier become a morbid process.

Martin Fischer maintains that acute nephritis is due to a toxic acidosis. He regards the albuminuria of athletes as due to a physiological acidosis. The difference he looks upon as one of degree, not of kind. Osler remarks that "common febrile albuminuria ..... represents the first link in the chain leading to acute Bright's disease." May not the same remark apply to the albuminuria of exertion?

All things considered, it seems possible that the most fruitful line of research as to the causation of this condition would be on the alterations of metabolism produced by fatigue, meaning by fatigue the bodily state produced by exertion, lack of sleep, and exposure.

Such an investigation might well also throw light on the etiology of that large class of cases occurring in civilian life and usually described as nephritis *a frigore*, for clinically the difference between these and the "trench" nephritis cases does not seem to be great. The prognosis in "trench" nephritis seems to be slightly better than in the civilian disease, but this may be accounted for by the fact that the former condition occurs among more or less picked men. Various writers have called attention to the great frequency of pulmonary complications, particularly bronchitis, in the military cases. The obvious explanation of this would be the infection of an œdematous lung from a pre-existing mild bronchitis, such as is common enough among the men in the colder months. Tytler and Ryle, in the article above quoted, draw attention to a deposition of fibrin in the walls of the lung alveoli of some of their cases which came to post-mortem. This condition, they state, is not found in ordinary nephritis, and they regard it as pointing to the action of a local irritant. They also call attention to hæmorrhages into the spleen. It will be interesting to learn whether these changes can really be regarded as differentiating "trench" from civilian nephritis. The changes found by these investigators in the kidneys were apparently such as might well occur in a case of nephritis *a frigore*.

It would appear that the principal, if not the only, way in which "trench" nephritis differs from nephritis as seen in civil practice is in the greater frequency of its incidence. Acute nephritis is not a very common disease among civilians; the condition described above is decidedly common in the B.E.F., though exact figures as to its incidence per 1000 are not now obtainable. What is the factor common to both soldiers and civilians, but more potently effective among the former than the latter? Such a common factor is excessive and prolonged fatigue, combined with exposure to cold and wet.

In conclusion it may be stated that such evidence as is provided by the consideration of the above series seems to indicate that the condition known as "trench" nephritis differs little from nephritis as met with in civilian practice except in the greater frequency of its occurrence, and that it is either a primary acute nephritis or an exacerbation of pre-existing disease, induced by fatigue and exposure.

My thanks are due to Colonel T. R. Elliott, A.M.S., consultant physician to the Boulogne Base, through whose courtesy the organisation of the National Research Committee for following the after-histories of patients was placed at my disposal; to the medical officers of the home hospitals who filled in and returned the schedules, thus making possible the section on prognosis; and to the nursing staff of the wards at the base hospital in France, whose unflagging zeal made possible the collection of the clinical material.

"OBSCURE EPIDEMIC ENCEPHALITIS."

SOME OBSERVATIONS ON BLOOD COUNTS AND CEREBRO-SPINAL FLUID.

BY S. K. VAIDYA, M.R.C.S. ENG., D.T.M. & H. CANTAB., L.M. & S. BOMBAY, &C.,

ASSISTANT CLINICAL PATHOLOGIST, LONDON HOSPITAL.

(*From the Hale Clinical Laboratory, London Hospital.*)

WITH the object of ascertaining the condition of spinal fluid and blood in this disease I have examined a number of cases of "obscure encephalitis" under observation at the London Hospital.

Findings in Epidemic Poliomyelitis.

I consider it material to refer briefly to the findings summarised in the Rockefeller Institute Monograph No. 4 (1912) and Dr. G. Draper's book on acute poliomyelitis (1917).

In the literature on poliomyelitis there are conflicting statements about leucocyte counts. L. E. La Fetra, in New York, reported six cases with a leucocytosis running from 13,000 to 20,000, while E. Müller, in Germany, reported 15 cases with a leukopenia of from 3000 to 5000. Though Gay and Lucas found leukopenia with lymphocytosis in monkeys, their leucocyte counts in human cases were 7800, 12,200, 11,600, 17,400, 12,000, and 13,400. Dr. F. W. Peabody and his co-workers' results can be summed up as under.

"We have found in the blood of patients with poliomyelitis a constant and marked leucocytosis. If taken in connexion with other available evidence a leucocytosis of from 15,000 to 30,000 is distinctly suggestive of the disease in question, especially if the polymorphonuclear cells are increased at the expense of the lymphocytes."

They find that this leucocytosis lasts for as many as seven weeks and is highest in the youngest children.

With regard to the spinal fluid "previous investigations have not been extensive nor have the examinations been careful." Gay and Lucas have recorded 75 to 100 per cent.

of mononuclear cells. Dr. Peabody and his colleagues examined 233 fluids from 69 cases, and they found that almost all were clear, colourless, and watery. Only a few showed the slightest opalescence. The type of cell present in the fluid was almost always the mononuclear. Though Flexner and Lewis and Lucas all record polymorphonuclear cells in the spinal fluid of their experimental monkeys up to 72 hours from the time of inoculations, Lucas in his 11 pre-paralytic human cases found only mononuclear cells. It must be stated that 2 out of 6 prodromal stage cases of the Rockefeller Institute showed polymorphonuclear cells. However, Dr. Draper describes many abortive and pre-paralytic cases in his book on acute poliomyelitis (1917), and he describes a "fluid whose clearness may or may not be impaired. It is rarely opalescent or turbid. Here at once is a gross point of difference from the fluid of cerebro-spinal meningitis." He also describes *polynuclear cells which are not polymorphonuclear cells* in the very early stages, but which are replaced by the end of 24 to 36 hours by small lymphocytes which represent 90 per cent. of the total number.

As regards protein, all the investigators have recorded a more or less definite excess.

In effect, according to the American investigators, a *leucocytosis* of from 15,000 to 30,000, combined with an excess of protein and a well-marked excess of mononuclear cells (small lymphocytes) in the spinal fluid is always present in cases of poliomyelitis. In a small percentage of cases polynuclear cells are said to occur in the spinal fluid in the prodromal stage.

Investigation of Cases of Epidemic Encephalitis.

My own results are as follows:—

Remarks.—Case 1. Drowsy; ptosis; delirious. *Case 2.* Drowsy; ptosis. *Case 3. Died.* Anaerobic blood culture negative. Ptosis; rash; drowsy. *Case 4. Died.* Landry's type. *Case 5.* Ptosis; later facial paralysis. *Case 6.* Drowsy; ptosis. Unfortunately spinal fluid was not examined a second time. Anaerobic blood culture negative. *Case 7.* Dazed. *Case 8.* Catatonia; unconscious. *Case 9.* Ptosis; drowsy; chorea; ? T.B. *Case 10.* Drowsy; lobar pneumonia. *Case 11.* Delirious; irritable. *Case 12.* This blood count was done 9 weeks after admission; ? ptosis. *Case 13. Died.* Drowsy; proved on P.M., T.B. *Case 14. Died;* delirious; drowsy. *Case 15.* Ptosis; mental and speech slurring. *Case 16.* Drowsy. *Case 17.* Vomiting and abdominal pain. *Case 18.* Irritability. *Case 19.* Drowsy. *Case 20.* Ptosis; convalescent.

Twenty cases were examined, all of which were considered to be examples of epidemic encephalitis. In all cases the blood was examined and in 12 cases the spinal fluid also. (See Table.)

In 2 cases the diagnosis was proved to be erroneous. Case 10, with a high leucocyte count and a practically normal spinal fluid, developed a typical attack of pneumonia. Case 13 had tubercle bacilli in spinal fluid and this result was confirmed post mortem. In the remaining 18 cases, with the possible exception of one or two doubtful ones, there was every reason to suppose that the diagnosis was correct.

Leucocyte counts.—With the exception of Case 10, which turned out to be pneumonia, in no case has the leucocyte count been as high as even 15,000 per c.mm.

In 18 counts done on 10 adults the average number of leucocytes was roughly 7600 per c.mm., while the average of 13 counts on 5 typical cases (Nos. 1, 2, 5, 6, and 8) was 7000 per c.mm. The average of 9 counts in children was about 9000 cells per c.mm. The normal number of white cells was found to be between 5000 and 6000 per c.mm. in adults and about 8000 per c.mm. in children. Thus it will appear that there is a *small leucocytosis* in cases of epidemic encephalitis both in adults and children.

Of the 4 fatal cases (Nos 3, 4, 13, 14) No. 13, with a count of 11,680, turned out to be tuberculous, while No. 3, with a count of 12,800, had a generalised hæmorrhagic rash and also a bedsore, which account for the inflammatory condition of his blood. The remaining two had counts of 9200 and 7040.

The counts in children in general were found to be higher. In view of the high count of one fatal case with tuberculous meningitis (No. 13) it is a pity that the spinal fluid was not available for examination in these cases.

As regards the question of leucopenia, it can be stated that *no leucopenia* was found in these cases. Cases 9 and 12, with counts of 4000 and 3600, were both doubtful cases.

The average number of polymorphonuclear leucocytes was found to be 66 per cent. in adults and 45 per cent. in children. As the average number of these white cells in normal counts is about 60 per cent. in adults and 40 per cent. in children, it would appear from the averages that there was only a slight tendency to polymorphonuclear increase. However, there were a few counts in which the relative proportion of polymorphonuclear leucocytes had decidedly increased.

Cerebro-spinal fluid.—The spinal fluids examined either showed nothing abnormal or only a small excess of protein and a small excess of cells which were found to be small lymphocytes. The fluids were in all cases practically clear and in no case was opalescence noticed. Case 13, which had a cobweb and a very large excess of protein and cells was proved to be tuberculous.

Conclusions.

1. The very small amount of leucocytosis—viz., 8000 to 9000 per c.mm.—in cases of epidemic encephalitis falls far short of the pronounced leucocytosis—viz., 15,000 to 30,000—recorded at the Rockefeller Institute in cases of poliomyelitis.

2. The cerebro-spinal fluid is not as grossly affected as in poliomyelitis in which often cell counts running into several hundreds and sometimes exceeding 1000 per c.mm. have been recorded. As a matter of fact, the deviation from the normal is very small.

3. In view of the very small deviation from the normal both of the blood and the spinal fluid in cases of epidemic encephalitis, and especially in the absence of successful experimental communication of the disease to monkeys with the production of paralysis, in my opinion we are not justified in asserting that the virus of epidemic encephalitis is the same as in poliomyelitis.

4. Although the results of the examinations of the blood and the spinal fluid afford no positive proof in support of a diagnosis of epidemic encephalitis, such negative results will materially help in ruling out a number of other obscure cerebral conditions, as was found to be the case in those due to pneumonia and tuberculous meningitis recorded above. It is therefore considered advisable to have recourse to such examinations in all cases likely to be classed as those of epidemic encephalitis on clinical grounds.

I am very much indebted to my chief, Dr. P. N. Panton, for his very valuable advice and guidance. I am also much obliged to my colleague, Dr. Harold E. Bates, for his helpful criticisms and suggestions.

INFLUENZA AND PURULENT BRONCHITIS.

BY A. MAUDE, M.R.C.S., L.R.C.P. LOND.,

CAPTAIN, R.A.M.C.; MEDICAL OFFICER IN CHARGE OF MEDICAL CASES, MILITARY HOSPITAL, THETFORD.

HAVING had the questionable advantage of seeing every epidemic of influenza in England since 1889 my impression of the peculiarities of this outbreak in June, 1918, may be of value. The uncomplicated cases have been characterised by very short incubation (when the facts could be ascertained) and sudden onset. Most of the men complained of initial giddiness, even prior to the usual headache and generalised pain. Conjunctivitis was present in a large number, infection of the throat and tonsils was comparatively rare, and gastric cases were conspicuous by their absence, only occurring in the subjects of previous gastric affection.

Onset.—The young soldiers of graduated training battalions showed a tendency to profound stupor and drowsiness, lasting for several days, a condition probably due to the constant elimination of fatigue products, to which the influenza toxin had been superadded. In nearly all cases the tongue had been extremely coated, tending to early drying of epithelium. There were 2067 men sick with influenza reported in two commands of a combined strength of 10,000 men between June 18th and July 18th, of whom 248 were admitted to hospital. A high proportion of these developed the complex lung condition, described by Lieutenant J. A. B. Hammond, R.A.M.C., as purulent bronchitis,[1] and it may be of advantage to contrast our cases with those recorded in the Aldershot report. In the Thetford outbreak a large number showed a frank lobar pneumonia, usually of the lower lobes only, but in three instances the consolidation was apical. The apical cases were, as usual, severe and accompanied by acute, brief delirium.

Physical Signs.—In the early stages it is remarkable how slow the auscultatory signs are in developing; several days of high temperature may elapse without crepitation or bronchial breathing being audible. There is little relation between the extent of physical signs and the temperature, either at the beginning or during the stage of resolution. The commonest type was a pneumonia of limited extent, accompanied, and often preceded, by coarse bronchial signs indicating a bronchitis of the larger tubes. The pneumonic patches were often bilateral and showed a marked tendency to spread, combine, and wander. The combination of coarse bronchitis and lobar pneumonia produced grave dyspnœa and profound effects on the heart, especially on its right side. The physical signs of bronchitis were frequently present, combined with patchy signs of consolidation. In a large proportion the signs of bronchitis supervened upon those of localised pneumonia. In many instances the bronchitis was one-sided, showing its infective quality. Small patches of collapsed lung were a frequent sequel of this bronchitis; the collapse was in all cases of short duration and completely cleared up.

Sputum.—The sputum in hardly any instance showed the "prune-juice" staining of ordinary pneumonia, though in some cases it was tinged with bright blood in streaks or tiny bright clots (bronchial); in one youthful patient occurred several hæmoptyses of large dark clots, perhaps issuing from an acute bronchiectasis. The usual colour in the pneumonic cases was a faint crushed strawberry, the expectoration became eventually peculiarly tenacious, yellow, consisting of almost pure pus, and frequently in tough curdled casts, evidently brought from middle-sized bronchi. In no case was any offensive odour of sputum present. No systematic bacteriological examination was undertaken, but the researches of Dr. J. W. H. Eyre[2] and Captain W. Rolland,[3] R.A.M.C., have established the question of double successive infection by the influenza bacillus and the pneumococcus.

Pleurisy.—A large number of cases showed pleuritic patches, in most instances at the right base, and a large pleural effusion was formed in one boy of 18, and smaller effusions in others. In a considerable proportion a pleurisy was the herald of the lung attack.

Complexion.—The "heliotrope" complexion, noted in the Aldershot report, was present in many of the worst cases, but these were not so uniformly fatal as that report suggests; there were many recoveries of men in whom this aspect was quite marked.

Temperature.—Hardly any of the cases of defined lobar pneumonia terminated by crisis, and in a high percentage the lysis was very irregular, manifesting a high evening rise for many days, with a definite fall to normal, or near normal. The pyrexia in the pneumonic cases was high, reaching sometimes 105° or 106°, but in only one instance was there a chart of typically pneumonic character. A fall in temperature, whether sudden or gradual, was frequently delusive, being followed by renewed pyrexia. And when purulent expectoration was well established a swinging type with a range of several degrees, as noted by Lieutenant Hammond, was observed.

Prognosis.—The severer cases were characterised by very rapid emaciation, out of all proportion to the duration or severity of the pyrexia. Out of the 250 men admitted to hospital only three died, all from extensive double pneumonia, two being young subjects, and the third a middle-aged subject of chronic bronchitis. Had the epidemic occurred at a less favourable time of year the mortality must have been heavier. Several of the most seriously affected were the subjects of previous acute or chronic bronchitis.

Treatment.—We found that the most useful routine line of treatment was by expectorants, combined with free alcoholic stimulation and heart tonics. The worst cases were kept in the open air in an enclosed corridor, and cold and tepid sponging was resorted to freely in cases of high temperature. Pulmonary antiseptics and inhalations proved useless, and oxygen did not appear to be of value, while atropine seemed to interfere with pulmonary secretion and do more harm than good.

I am indebted to Lieutenant-Colonel H. W. Laing, R.A.M.C., and Major Kennedy Taylor, R.A.M.C., for valuable statistical information.

AN "INFLUENZA" OUTBREAK.

BY C. W. WIRGMAN, M.D. LOND, F.R.C.S. ENG.,

CAPTAIN, R.A.M.C. (T.F.)

THE recent epidemic has been such a rush for most of those who have to deal with the victims that any detailed account of a number of cases is likely to be left till the pressure is over, and so notes of the earlier cases may be lost for lack of leisure.

I have been so situated that it was possible to keep short notes from the start of an outbreak. Also, I was in charge of a body of troops under identical conditions and training, so that data were easily compiled.

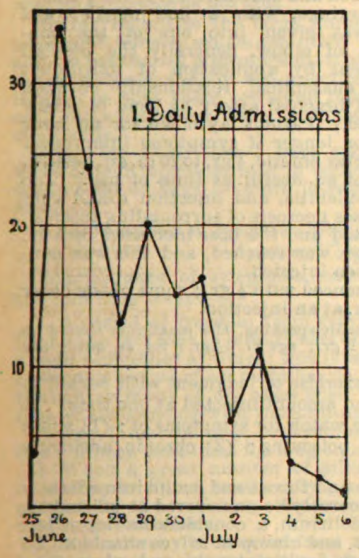
The following notes do not pretend to be more than a record of how one particular set of patients were affected. They are not meant to be a general description of all the features of the present outbreak, but only of a type found in a body of normal adults. The unit in question really consisted of two detachments (A 1 men, with a few exceptions). They were camped in the same field, their tents were side by side, and their work was identical. For all practical purposes they may be considered as one unit. The total strength (all ranks) in camp was 516. The epidemic probably began on June 24th, but the first definite cases were observed on the 25th. The record is closed on July 6th as one unit moved out on that date. The new cases ceased coincidently.

Speaking generally, none of the patients gave cause for any real anxiety as to the upshot of the attack. No more serious condition than one attack of bronchitis (slight) occurred. The cases admitted to hospital (from camp hospital) were only 14 in all, and the usual reason for admission was persistent temperature of 99° F. or over.

The subjective symptoms complained of were headache, usually frontal, pains in back and limbs, soreness or pain in eyes, sore-throat, particularly in the later admissions, cough, and sometimes abdominal pain. The temperature ruled about 101° to 104°, none rising to 105°, and a few not reaching 100°. By the third day the temperature, as a rule, was below 99°. The average stay in hospital, including day of admission and day of discharge, was 3½ days. The first symptom to disappear was the headache and the last the backache.

The earlier cases exhibited a marked tendency to conjunctivitis and the later ones to pharyngitis. Both of these

were slight, but the pharyngitis appeared to cause considerable discomfort. Laryngitis was not uncommon, and cough was frequent and troublesome. The pulse-rate was not rapid, considering the temperatures, and usually fell, when the temperature became normal, to about 80 per min. The tongue in nearly every case was heavily furred. In 11 cases labial herpes was severe.



The age of men affected was very interesting. At first the younger men went down, while as time went on it was the older ones who succumbed.

The figures were as follows:—

No. in camp under 19	...	157
Over 19 and under 20	...	72
,, 20		287
Total		516

No. of influenza cases:—

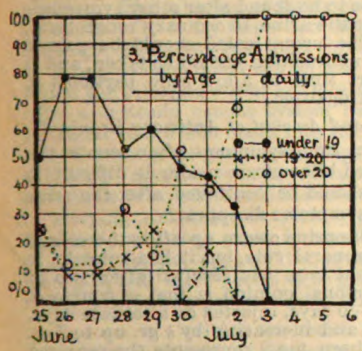
	Epistaxis ...	2	1·3
	Diarrhœa ...	3	2·0

Treatment of symptoms by drugs was unavailing. Rest in bed till the temperature subsided was the only thing that could be done.



As to methods of prophylaxis, avoidance of confined atmospheres, as far as possible, was insisted upon; morning and evening nasal lavage and gargling with normal saline was carried out. Coughing, spitting, and cigarette-smoking were discouraged.

Tents were struck frequently and bedding put out in the sun daily.

The graphs attached show: (1) total daily admissions; (2) admissions by age, daily; and (3) per cent. admissions by age, daily.

SHORTAGE OF NURSES.—The Queen's Hospital for Children (Hackney-road, London, E. 2) is appealing, with the support of the Bishop of London, for the nursing service at the hospital. The number of beds lying vacant for want of nurses is now 24, with a prospect of further reduction in the near future. The weekly attendances at the hospital number about 2000.

THE SUCCESSFUL USE OF ANTIMONY IN BILHARZIOSIS

ADMINISTERED AS INTRAVENOUS INJECTIONS OF ANTIMONIUM TARTARATUM (TARTAR EMETIC).

BY J. B. CHRISTOPHERSON, M.A., M.D. CANTAB., F.R.C P. LOND., F.R.C.S. ENG.,
DIRECTOR OF THE CIVIL HOSPITALS, KHARTOUM AND OMDURMAN.

AFTER trying and confirming the conclusions of previous workers on the use of intravenous injection of antimonium tartaratum (tartar emetic) in cases of Oriental sore, internal leishmaniasis, and naso-oral leishmaniasis (espundia) as found in the Sudan,[1] in May, 1917, I commenced at the Khartoum Civil Hospital to treat bilharziosis (vesical and rectal) by the same drug. Amongst the natives of the Sudan bilharziosis is not so frequent as amongst Egyptians; still, in the clinic of a hospital such as Khartoum Civil Hospital there are sufficient cases to give the treatment a very fair trial.

The treatment of bilharziosis up to the present has been altogether palliative and unsatisfactory. It has baffled all attempts to find a satisfactory remedy. Time was the sole hope of cure, but as time takes years (a considerable number, perhaps 10)* to effect a cure, and in the meanwhile the patient is running no small risk, to say nothing of the pain and inconvenience of repeated attacks of cystitis and the debilitating effect of loss of blood, anything which promises even alleviation is to be welcomed.

There is no doubt that antimony given as intravenous injections of tartar emetic considerably interferes with the bilharzia and suspends its activities, even when it does not actually kill. My own opinion, based on the cases treated during the last year, is that antimony (antimony tartrate) is a definite cure for bilharziosis, and that the intravenous injections of tartar emetic kill the *Schistosomum hæmatobium* in the blood and render it harmless.

* Treatment suspended. † Relapse. ‡ Treatment not completed. § Details mislaid.

Record of Cases.

These observations are based on 13 cases of *Schistosomum hæmatobium* (see Table); more than 13, however, were treated by the method.

Three of the cases were 13 years of age or under, the remainder from 15 to 21. Three were Egyptians, the others natives of the Sudan. Three had relapses; the total amount of tartar emetic injected in these cases was:—

(1) 15 gr. in 6 injections in 10 days, relapse after 25 days.
(2) 10 gr. in 10 days, relapse after 8 months.
(3) Had 7 injections, relapse in one month.

Two patients were discharged before completion of treatment, being "time-expired" soldiers.

The case (No. 2) which relapsed in 25 days was an Egyptian soldier who had a heavy infection of bilharzia of rectum and bladder, and injections had to be suspended after six had been given in ten days (15 gr.) owing to phlebitis. He was one of the time-expired soldiers who would not remain in hospital after their time had expired.

In Case 4, Egyptian, the injections were suspended owing to the patient being weak, but they were resumed again after ten days. He had 22½ gr. of antimony tartrate in 13 injections in 30 days. He was 44 days in hospital; discharged at own request, being a "time-expired" soldier. The ova were very scanty, if present at all, on discharge, but as ova had only been absent a few days previous to discharge, this case can at most be put down as improved.

* Loos says the worms only live three to five years, while the eggs remain, and are the real cause of the disease.

The following case may be taken as a type.

CASE 7.—Patient, 15, student, Sudanese; pain on micturition and passage of a little blood with last portion of urine for one year. Bilharzia ova found in urine. Injections were commenced Nov. 14th, 1917, with 1/3 gr. antimony tartrate, increased by steps to 2 gr., injections being given every other day. On Dec. 10th (26 days after treatment) his urine became free from ova, after 21 gr. in 13 injections; treatment was continued until the 16th. He had in all 27 gr. in 16 injections in 32 days, without reaction. For three months he reported once a fortnight, and remained free from signs of bilharzia. On May 30th, 1918, his urine was normal to chemical and microscopical tests; he said he was cured, and there had been no signs of recurrence.

In the following case the patient relapsed after eight months:—

CASE 3.—Patient first seen in June, 1917; hæmaturia for five years; had never been free from it; no frequency or pain. When admitted the first time 22 gr. antimony tartrate were given in 20 days in 13 injections. They were generally well tolerated; on three or four occasions moderate reaction, local pain, rise of temperature, and some retching. The urine became clear after he had had 10 gr. ten days after admission; discharged for observation on June 30th, 1917.

Urine remained clear and free from blood and ova for eight months until March 12th, 1918, when it became smoky—microscopic blood was found and two B. ova. Injections were resumed with 1 gr. The next day 2 gr. were given; some reaction, rise of temperature, vomiting, metallic taste, and feeling of weakness. After a day's interval 2 gr. were injected again; he vomited three times, and had metallic taste in throat; injections reduced to 1½ gr. every other day. On one occasion he had nausea, diarrhœa, giddiness, with 1½ gr. He had 11 gr. injected in 12 days; then was discharged at request of his master; ova and blood had completely disappeared from urine. He was seen periodically until May 20th, no blood or ova present on any examination; is presumed cured.

After 22 gr. during first course, and 11 gr. during second course I trust that patient is cured.

CASE 8.—Patient, 17, student, Gordon College, was admitted to hospital for diarrhœa with blood in stools; lateral spiked B. ova were found. Treatment commenced with ½ gr. antimony tartrate; next day 1 gr., continued daily five times; then 2 gr. were injected. Cough, salivation, lacrymation, metallic taste in mouth, and vomiting ensued. After interval of one day 1½ gr. were injected every other day; slight reaction followed first two injections of 1½ gr.; then injections were well tolerated. Stools became free from B. ova after 13 gr. had been injected; patient had 25½ gr. in 19 injections in 28 days. No return of symptoms two months afterwards.

CASE 9.—Patient, 17, student, Gordon College, from Dongola Province; March 5th, 1918. Had passed blood in urine for three years or more; nearly every time blood came at end of micturition; very little pain. In December, 1917, he had come to hospital with same symptoms; received seven injections; was free from symptoms for a month, when they returned. Urine smoky, with heavy brown deposit; B. ova easily found. He commenced with ½ gr. antim. tartr., ½ gr. next day, 1 gr. third day until seventh day, when injections were discontinued owing to dermatitis of both elbows due to iodine. Injections were resumed after five days, 1 gr. being given, increased to 2 gr. next day, 2 gr. being given on two occasions; this was reduced to 1½ gr. every other day for three weeks. Urine became quite free from B. ova 25 days after treatment and remained so. In consequence of relapse patient had 29½ gr. antimony tartrate in 22 injections within a period of 28 days. No untoward symptoms except irritation due to iodine on the skin and reaction on two occasions, when 2 gr. were injected; metallic taste, giddiness, and vomiting once.

CASE 11.—Patient, 12, Egyptian, was infected at Damanhour in Egypt. For two and a half years he has passed blood in urine which, he said, was never free. The boy was anæmic to a degree, had dirty sallow complexion of person suffering from intestinal and other parasites, and was undersized; weight, 4 st. 13½ lb. Large number of B. ova in urine. He was, as usual, a week in hospital under observation before commencing treatment; he improved somewhat. Treatment commenced on April 6th, 1918, with ¼ gr.; two days later ½ gr. After five doses of ½ gr. every two days 1 gr. given on alternate days; then 1½ gr. The first 1½ gr. followed by cough, giddiness, vomiting. 1½ gr. dose was, however, continued for three times with no further reaction; 2 gr. were then given. Giddiness, nausea, and vomiting occurred. After two days this was repeated with the same result. Dose then reduced to 1½ gr. on alternate days; slight reaction. After three doses 2 gr. were again tried; vomiting occurred four times, giddiness all afternoon. Dose reduced to 1½ gr. on alternate days. 30 gr. altogether were given in 23 doses over 49 days.

This was an interesting case; the boy put on weight and his haggard expression became quite a happy one. The urine became normal, B. ova disappeared in about three weeks. He was still in hospital at the time of writing, but all symptoms and signs of bilharziosis had disappeared.

Loos[2] states that the ova remain and produce symptoms after the parent worms have died. This fact might account for the finding of a stray ovum in an apparently cured case; it would also account for the discovery of a small clot containing six or seven ova passed in Case 11 on April 22nd, 1918, 14 days after all other symptoms had disappeared, and subsequent to which nothing was discovered.

Method of Administration.

The method adopted was briefly as follows:—

The cases were all well-marked cases of bilharziosis of bladder or rectum, or both, of average intensity. The ova were easily found in the excretions. A careful note was made of: (1) the patient's (subjective) symptoms; (2) how long he had been infected; and especially (3) whether he had intervals of complete freedom from symptoms.

The patients were not kept in bed, rest having a tendency to allay the hæmaturia and bring about a temporary suspension of symptoms, &c. When possible the patient was under observation for a week previous to treatment, the urine being tested in the morning, when it might be free from blood, and in the evening after day's exercise, when it was more likely to contain blood and shreds.

A 10 c.cm. record syringe, with a fine needle, was used. The injection was given into one of the conspicuous veins at bend of elbow, generally the median cephalic, made prominent by application of tourniquet on upper arm. (The anatomical relationship between median basilic vein and brachial artery at bend of elbow should be borne in mind.) Patient lay down for an hour on bed after injection, or longer if symptoms intervened. The solution used was tartar emetic, ½ gr. to 20 m. aq. destill., and diluted with 2 vols. of aq. destill. at time of use. (Too strong solution causes phlebitis, and injection round vein instead of into vein causes necrosis of surrounding tissues.) The injection was repeated and the dose increased by ½ gr. every other day until 2 gr. was reached, and this was continued until 30 gr. had been injected.

A boy of 10 years commenced with ¼ gr.; some of the older cases had as much as 3 gr. at an injection.

It would appear that, generally speaking, the maximum should be for a boy of about age 10, 1 gr.; age 17, 1½ gr.; for an adult the maximum should be 2 gr.

There is scope for the exercise of judgment with regard to frequency of injection and amount injected at one time. It is essential to be on the watch for symptoms of: (1) acute and subacute antimony poisoning; (2) chronic antimony poisoning.

Metallic taste in mouth and throat and cough immediately after the injection need scarcely be considered as poisoning, but vomiting, giddiness, delirium, a considerable rise or fall in temperature, diarrhœa, and cramp in calves should all be taken seriously. They are danger signals, and when they occur the injections should be temporarily suspended, and when injections are resumed decreased in strength, and not given so often.

Rapid small pulse, cold clammy skin, signs of collapse, in fact, are serious symptoms of poisoning.

Chronic antimony poisoning should especially be watched for. Weakness, loss of weight, anæmia, glossitis, cracked tongue with ulcers, diarrhœa call for suspension of the antimony and for appropriate treatment.

Improvement in symptoms is often noticed after the second or third injection by the clearing up of the urine.

The disappearance of clots of blood, shreds, &c., of smokiness, is the first favourable sign, together with improvement of subjective symptoms. The ova disappear from the urine more gradually. The patient's own feelings form a good guide as to progress. He has had his complaint for some years, and quickly and accurately notices any improvement.

There is also the frequency, pain on micturition, and character of urine, and the objective symptoms of the patient to indicate improvement or otherwise, as well as patient's weight. Increase in weight, together with improvement in symptoms, is a favourable sign, whereas loss of weight and continuance of anæmia indicate chronic intoxication by the antimony. It is more necessary to be on the watch for loss than for gain in weight. There is the blood and albumin in the urine, all valuable in estimating result of treatment. Finally, the microscope is the most valuable guide of all, because ova may continue to be found after other symptoms have cleared up, and after the urine, to ordinary rough tests, has become normal. The urine tested should be passed fresh, that at the end of micturition should be taken, and it should stand for a short time to allow solid particles to settle, or it may be centrifugalised.

When to Stop Injections and Amount of Antimony Required.

The periods of freedom from symptoms often seen in the natural course of untreated bilharziosis render it difficult to say how long injections should be continued after the urine becomes normal and the symptoms disappear.

As previously stated, the urine clears up after the second or third injection, as a general rule, but it is a mistake to conclude that a permanent cure has resulted after two or three injections. My personal opinion is that a course of injections lasting over 15–30 days, injected on alternate days, commencing with ½ gr., and increasing by ½ gr. up to 2 gr. or 3 gr. until 30 gr. have been used, represents the required killing dose. In this connexion it may be said that cases of bilharziosis do not, as a rule, suffer from the intense debility that is found in leishmaniasis, and so the debilitating and poisonous effects of the drug are not so readily produced, and the same amount of watchfulness is not so necessary in cases of bilharziosis as in leishmaniasis. The chronic toxic effects of the drug must be looked for in bilharziosis rather than the acute toxic effects which are more likely to be seen in treating leishmaniasis with antimony.

I do not think that injections of less than 1 gr. each time have much effect on the *Schistosomum hæmatobium*, but

injections of less than 1 gr. are necessary to commence with in order to establish a tolerance for the drug.

We thought that we noticed in cases of boys where a small dose was used to commence with, and where the dose was not increased with sufficient rapidity, that there was a tendency for the bilharzia to establish a tolerance for this drug.

Having regard to the large number of bilharzia worms, male and female, which are often seen in the portal vein and its tributaries post mortem, it may happen that all are not equally affected by the injection. Some are killed, but it may be that there are some remain whose activities are only suspended for a time, thus accounting for a return of symptoms.

From the experience I have gained my opinion is that three or four injections may in some cases effect a cure, but that a total of 30 gr. or more is required lasting over 15–30 days.

Reappearance of Symptoms after Period of Freedom or Apparent Cure.

Reappearance of symptoms may be explained in one of the following ways:—

1. A period of freedom from symptoms may be accounted for by the fact that in bilharziosis clinical symptoms may be absent altogether at times; this is tantamount to saying that antimony has no effect on bilharzia. It is scarcely possible that in so many of the cases tried these natural periods of rest would coincide with the administration of tartar emetic.
2. The bilharzia may be scotched, not killed—treatment has not been continued for long enough.
3. When a great number of bilharzia worms are present some may be killed, others only placed temporarily hors de combat by the antimony treatment. Some may be more resisting than others.
4. As antimony is excreted from mucous surfaces and the bilharzia worm does not like antimony, it may avoid the mucous surfaces (bladder and rectum) whilst the antimony is being excreted. In other words, it will return to the portal vein whilst the mucous surfaces are infected with antimony. In this way its activities may be suspended for some time, as antimony is an accumulative poison, and remains in the tissues for some considerable time.

The bilharzia worms by instinct will find their way back to the bladder and rectum in order to deposit their ova as soon as these organs become free from antimony. Relapses may possibly be accounted for in this way.

5. Re-infection. This is not likely—in any case not for some months afterwards.

Further Points in Treatment.

It must be remembered that tartar emetic is a poison; ¼ gr. has caused death in a child, 2 gr. in an adult.[3] It is an accumulative poison. On the other hand, large doses have been tolerated. It is safe to say that, generally speaking, for children the commencing dose should be ¼ gr. and for adults ½ gr., but the maximum dose should be reached as soon as possible.

It has always appeared to me that the logical and natural way to attack bilharzia would be directly through the blood stream, and in the case of vesical infection through the dorsal vein of the penis, which terminates in the pudendal plexus, surrounding the prostate, the neck, and the fundus of the bladder. The injection of tartar emetic into the veins offers an opportunity to try this where the dorsal vein of the penis is conspicuous. The vein joins the hæmorrhoidal plexus, and so directly communicates with the portal venous system in which the bilharzia worms are located; it also communicates with a systemic venous system by means of the internal pudendal vein which opens into the internal iliac.

Of the two great germicidal drugs we possess—arsenic and antimony—arsenic given as salvarsan and atoxyl appears to have little or no effect on *Schistosomum hæmatobium*, although in sleeping sickness, yaws, and syphilis it displays specific qualities; antimony given in the form of a metallic salt, or as tartar emetic, appears to be a specific cure for leishmaniasis, and there seems to be good reason to believe that it is a specific cure in the case of bilharziosis as well.

Other Successful Results.

In confirmation of the extremely satisfactory results I have obtained during the year in the intravenous injection of antimony (tartar emetic), Dr. V. S. Hodson, who very kindly continued the treatment of bilharzia cases with tartar emetic at Khartoum Civil Hospital during my absence in 1917, and afterwards at Atbara, carried on a series of trials quite independently, sends me the successful results of the treatment of seven cases.

Dr. Hodson has for some years been working at the treatment of bilharzia, and it is of particular interest to have his favourable opinion on the cases treated by antimony. Of his 7 cases, 5 had 4 injections; 1 had 3 injections; 1 had 2 injections. He commences with ½ gr., and injects every other day for three injections, increasing ½ gr. each injection—the interval between 1½ gr. and 2 gr. being three days or longer.

The immediate result of this method was found to be satisfactory, but I am personally inclined to think that three or four injections will not give a permanent result, although sufficient to paralyse the activity of the worm for a time.

Some Necessary Precautions.

Finally, I would point out that the intravenous treatment of both bilharziosis and leishmaniasis by antimony should be undertaken with:—

1. Appropriate and reliable apparatus which is not necessarily elaborate and expensive—e.g., a proper syringe and needle and sterilising arrangements for the same, and small flasks for keeping the solution in, &c.
2. A proper sense of responsibility when injecting remedies directly into the general circulation viâ the vein.
3. The due appreciation of the fact that the drug injected is a poison, and that its reckless use will kill the patient.
4. The exercise of judgment as to dosage and length of time of administration, stopping altogether, suspending, increasing dosage, according to circumstances.
5. And last, but not least, a good note should be made of the case before commencing treatment and a daily note of symptoms during the treatment, examination of urine and fæces, &c., without which any useful conclusion will be impossible. The subsequent history for a considerable time should be watched.

Without these the placing of intravenous injections as routine treatment in the hands of medical officers in outstations and elsewhere whilst such treatment is in the experimental stage will do more harm than good, and will bring discredit, perhaps undeserved, on the remedy.

In conclusion, I would thank Dr. Mustafa Izzedin, who has done so much of the work of injecting these cases, and Mr. J. R. Newlove, who has carried out many of the microscopic examinations connected with the urine.

A CASE OF ACUTE DELIRIOUS MANIA: RECOVERY.

BY F. WYATT-SMITH, M.B., B.C. CANTAB.

THE combination of fever, mania, constipation, and insomnia in a clinical picture is sufficiently rare to make the publication of the following case desirable, especially in view of recovery having taken place.

A man, aged 28, was discharged from the Army as "unfit" two years ago. Since then, never robust, he has been continually overworking himself at a munition factory at Woolwich, his only holidays being a few interruptions through illness. On June 22nd, 1918, a Saturday, he could not go to work, being flushed, feverish, delirious, and suffering from headache. He continued in this condition until the following Tuesday (the 25th), when, suddenly, unexpectedly, and without any warning, he attempted to cut his throat, and was brought to Constance-road Institution, East Dulwich, struggling violently with four policemen, and admitted. He was so violent that, I being temporarily absent, a neighbouring practitioner was called in, and at 5.20 P.M. gave him I.H. hyosc. hydrobrom., gr. 1/100, and ordered gloves to be used if necessary. The patient slept for three and a half hours. At 11 P.M. I saw him. He was then awake, flushed, with two men standing over him to prevent his falling out of bed, and so restless that I could not take his temperature. As there was a good deal of influenza at Woolwich at the time, I thought he might be suffering from a toxic delirium and gave him tr. quininæ amm., 1 dr. three-hourly; calomel, 5 gr., statim; and paraldehyde, 2 dr.

On the next morning (the 26th) I found that he had had but a few snatches of sleep up to 3 A.M. and none since, and that he had tried to drink his urine during the night. He was talkative, incoherent, resistive, restless, abusive, and obscene, but I thought his physical condition had improved. T. 99·6° F. I ordered him 20 gr. of sulphonal, night and morning. At 3 P.M. he had marked flight of ideas, with rhyming and punning. At 6.30 P.M. his temperature was 102° in spite of the quinine he had been taking, and, after four days illness, made me doubt if he was suffering from the present mild epidemic of influenza, so, thinking that the quinine might possibly be giving him headache, though

he made no complaint of any, I withdrew it, and, his bowels not having been open since admission, I gave him an ounce of senna mixture. At 8 P.M., as he had had no sleep since 3 o'clock in the morning, and very little since admission, I gave him I.H. hyosc. hydrobrom., gr. 1/33. At midnight he had not slept, his delirium was low and muttering, his pulse weak, and his breathing shallow. In fact, he was in an alarming condition. As he was suffering with all four of the cardinal symptoms of acute delirious mania, I supposed he must inevitably die, dared not give him any more hyoscine in consequence, and, *faute de mieux*, and partly to see what it could do in the way of "bucking him up," I gave him 2 oz. of mist. amm. and ether.

On the morning of the 27th, except that his bowels had been open and that, as he fortunately had done all through, he continued to take nourishment well, his physical condition was much the same—namely, T. 103°, P. 132, R. 60 and shallow—he was very weak and had had only 40 minutes' sleep. All the stimulating effect of the ammonia and ether seemed to have been exercised on his brain, and here it had been only too successful, for again he was very noisy, restless, and hysterical. I determined that, like the Nurse in Tennyson, "he must sleep or he would die," so gave him I.H. hyosc., gr. 1/50, at 11.45 A.M. After this he was somewhat quieter, and slept a little at times. He was much quieter towards evening, and his temperature had fallen to 100° at 6 P.M. Throughout the night he was quiet on the whole, groaning and mumbling at times, but he had no real sleep, only dozing occasionally for a few minutes.

June 28th: Though, owing to some misunderstanding, he got no more sulphonal after 8.30 A.M. on the 27th, he now continued to improve steadily. The charge attendant's day report says: "Seems much better. Quieter, dozing and sleeping at times during the day." He continued to take nourishment very well, and his pulse, temperature (99·2° at 6 P.M.), and respirations henceforth ceased to be a feature. His bowels, too, acted well during the night, and gave no further trouble. The night report says: "Moaning and wandering in his talk at times. Fairly well and quiet on the whole. Slept at small intervals, and fairly well after 3.15 A.M."

On the morning of the 29th, the eighth day of his illness, he announced that he felt much better. In fact, he was now quiet and sensible and, except that he was troubled with a little bronchitis, made an almost uninterrupted recovery. (I may interpolate here that I noticed harsh breathing on his admission, and thought that his impatience, with his dyspnœa, might account for his habit of plucking at his throat and tongue, as also, perhaps, for his having attempted to cut his throat, the marks of which were then visible on the left side of his neck.) He was very thin, weak, and exhausted, but on July 3rd he sat up, and on the 11th was transferred to the general wards "time expired."

Did this man suffer from acute delirious mania or not? If not, what was the matter with him? He had all the classical symptoms, though it must be admitted that the constipation was not very obstinate. And then he did not die. These are objections. But, in answer, it may be asked, How marked must the individual symptoms be in order that they may count? and remembered that the authorities do not state definitely that the cases never recover. Against the view that the case was a toxic psychosis and the poison influenza are the facts that (1) the epidemic was a mild one; (2) the delirium was very severe; (3) no complaint was made of pain, except for a little headache late on in the case, unless the uneasy plucking at the throat (? air hunger) is to be so regarded; (4) the "picture" struck me as typically maniacal; (5) and, lastly, after the disappearance of the fever and the delirium a mildly demented condition remained, which seemed to me more marked than the exhaustion of the illness would account for.

The patient's hands and forearms were stained yellow on admission, and I inquired about toluol, but learned that he never went near it. He now tells me that this staining is due to C.E. powder, which he has to handle though he does not make it; but the stuff is said to be absolutely harmless to all who come in contact with it, and no precautions are taken against it.

If this was a case of poison psychosis, then how are we to diagnose acute delirious mania? Has a possibility of intoxication been excluded in all the cases recorded? And, if not, is it certain that this rare combination of fever, mania, constipation, and insomnia is a disease entity at all? If there is such a thing, then I cannot help thinking this was it. And, if so, the fact of recovery from the condition makes doubly interesting a case worth publishing in any event.

Constance-road Institution, East Dulwich.

Reviews and Notices of Books.

A Plea for the Insane. By L. A. WEATHERLY, M.D. With Foreword by Dr. T. B. HYSLOP. London: Grant Richards. 1918. Pp. 288. Price 10*s.* 6*d.*

OUR national methods of dealing with mental disorders are far from satisfactory, if only because early treatment is largely denied to persons in danger of mental breakdown. For a poor woman on the verge of melancholia little or nothing can be done; no general hospital will receive her, she cannot be admitted as a voluntary boarder in a public asylum, and convalescent or nursing homes, even if available, cannot give the necessary care and attention. So it comes about that until she becomes worse and can be certified as insane she must remain without effective treatment. There is, moreover, an ignorant public prejudice in relation to mental disease; it is regarded as disgraceful to need mental treatment, and this fact leads to concealment of threatening conditions. Even those who spend their lives in ministering to the insane are often looked at askance; at any rate, the law is often administered as though suspects were being dealt with. The requirements in the way of forms, returns, and reports in hospitals for the insane suggest that abuses, existent in some measure very many years ago, still persist; but it is time that the public ceased to regard these institutions from the point of view of Henry Cockton. But while the amenities of legal shelter for the insane have so much improved, the law in many directions is prejudicial to the interests of the insane, for it raises a mischievous barrier between the general public and the mentally afflicted, and tries to make a hard-and-fast line where it cannot be drawn.

Dr. Weatherly's book, "A Plea for the Insane," is therefore a very timely work. If his attitude to many questions is one-sided, this is the result of personal experience, while a lively style and the recital of cases and stories make the work pleasant reading. Many of his recommendations will obtain the unqualified support of the medical profession. The need for special hospitals or clinics for the treatment of nervous and mental disorders in their early stages is now generally admitted, and that it should be possible for persons who desire it to be admitted voluntarily in public asylums. Few will object to the suggestion that the Lord Chancellor's Visitors should visit all patients whose affairs are administered by a receiver appointed under the 116th section of the Lunacy Act, and that magistrates shall be required to examine in private and not in the public courts persons alleged to be insane and not under proper control. It is widely felt that the larger asylums are much too large and that it is better that patients should be placed in a colony or village, living in small detached houses; also that medical superintendents have too much administrative work, and that the number of patients under the care of assistant medical officers is far too great for proper and effective treatment. Other of Dr. Weatherly's views will not receive such ready endorsement. In reference to the treatment of mental disorders in their early stages Dr. Weatherly proposes that homes should be approved by the Board of Control in which patients may be received, and if necessary detained, upon "notification" to the Board. It would have been interesting if the difficulties inherent in this proposal had been more fully discussed. As regards the poor there can be no two opinions as to the desirability of establishing clinics or special pavilions attached to, or affiliated with, hospitals and universities. The need has been long recognised and repeatedly advocated in these columns. But the question of detention raises serious difficulty, which is greatly increased when wealthy patients are concerned. In America many psychopathic hospitals are conducted entirely on a voluntary basis; so also is the Lady Chichester Hospital at Brighton, which Dr. Weatherly so warmly commends. This question of notification, carrying with it the power of detention in approved homes, requires more hard thinking than Dr Weatherly appears to have given to it. Many persons will question the desirability of establishing what will virtually be new licensed houses throughout the country. That something must be done in this direction all familiar with the subject will admit, but it cannot be said the problem is solved in the book before us. Dr. Weatherly

proposes that lunacy administration should be decentralised and that many of the duties of the Board of Control should be discharged by district commissioners or by committees of magistrates. It seems probable that patients and their friends would frequently prefer that certificates and reports concerning them should be sent to a Government department rather than to some local body of magistrates. The Board of Control is freely criticised, and though no names are mentioned it is not difficult to guess to whom reference is made. The statement, "I want to say, in spite of many faults, the Board of Control are actuated by the very best motives, and have to administer a silly pernicious Act, drafted by God knows whom," does not make full *amende* for a display of bias.

Dr. Weatherly proposes that the Lunacy Act should be scrapped and that the new one should entirely omit the words "lunacy" and "asylum." He does not seem to realise that any word or phrase that may be substituted will soon acquire a similar objectionable meaning and that it is not a matter of words, but of the attitude of the public towards mental disorder that needs alteration.

The law in relation to criminal responsibility is strongly condemned, especially the MacNaghten judgment of 1843, which fixes responsibility by the possession of an ability to know right from wrong. In this connexion several interesting cases are quoted at length. Two trials for murder by a judge whose name is not given are especially noteworthy. One was a case of marked epilepsy, and though the judge summed up strongly against the medical evidence the jury brought in a verdict of "Guilty, but insane." A week later the same judge tried a lad for murder committed without any known provocation. Dr. Weatherly again gave evidence as to responsibility, but the judge ridiculed the view and the boy was condemned to death. He was afterwards reprieved and the event showed that Dr. Weatherly's views were correct, as the lad soon became demented. Later Dr. Weatherly came into personal relations with the judge in question, who apologised to him for his attitude on these two occasions. For Dr. Mercier's views on criminal responsibility Dr. Weatherly finds some hard terms.

Dr. Weatherly's advocacy of the use of mechanical restraint in actively suicidal patients will not commend itself to alienists generally, and several of his remarks about public asylums and registered hospitals are, to say the least, uncalled for. He makes a great point of the lack of proper medical care in the large asylums, and to support this shows the cost per patient for drugs and instruments in county asylums, in registered hospitals, in his former private asylum, and in his present home for early undeveloped cases. This average cost is respectively 4*s.* 4*d.*, 10*s.* 10*d.*, £3 17*s.* 9*d.*, and £17. These figures are interesting, but are quite valueless unless we know what kind of patient is under care and what is included under the head of drugs and instruments. It would be just as fair to conclude from these figures that in Dr. Weatherly's practice too many drugs are given. The attempt to create a prejudice against institutions by means such as this must be strongly censured.

In spite of the defects which we have indicated the book is a valuable one and is truly a powerful plea for the insane; yet it is to be regretted that its value is reduced by the inclusion of ungenerous reflections on many workers as zealous as the author in the same cause. The book is likely to run into further editions, when opportunity might be taken to reconsider some of these passages.

The Errors of Accommodation and Refraction of the Eye and their Treatment. By ERNEST CLARKE, M.D. Lond., F.R.C.S. Eng. Fourth edition. One coloured plate and 92 figures. London: Baillière, Tindall, and Cox. 1918. Pp. 243. Price 6*s.* net.

No very material alterations in this excellent text-book have been made since the publication of the third edition seven years ago, though parts of it have been amplified. The importance of correcting small degrees of astigmatism in the presence of any symptoms of eye-strain is one of the author's strong points, and among these symptoms are now included neurasthenic symptoms in soldiers suffering from shell shock or head injuries; also the continual blinking of the eyes sometimes seen in children. From this point of view it is especially necessary to correct the smaller degrees of astigmatism (under 0·5 D.), the theory being that the unequal contraction of the ciliary muscle is capable of neutralising them in the absence of a correcting lens, but only by expenditure of an undue amount of nervous energy. As this is the view emphasised by the author, we do not understand how he can still be of the opinion that the ophthalmometer is a more delicate test than the method of retinoscopy, for it does not profess to measure the total but only the corneal astigmatism. That of the lens when the ciliary muscle is put out of action, though never considerable, may nevertheless be of great importance, and of this the ophthalmometer gives no indication.

La Gangrène gazeuse. Par M. WEINBERG and P. SÉGUIN. Monographies de l'Institut Pasteur. Paris: Masson et Cie. 1918. Pp. 444. Price 20 francs.

WHILE the subject of this contribution appeals mainly to bacteriologists and laboratory workers, none the less it contains much information useful to the clinician and notably to the surgeon.

The first section of the monograph, devoted to the general question of gas-gangrene infection, is especially illuminating, and its perusal is recommended to all who are interested in the treatment of wounds. The controversy concerning what precisely is the causal agent of gas gangrene is fully discussed, and attention is called to a factor that cannot be sufficiently emphasised—viz., that one clinical entity may be produced by infection with more than one specific micro-organism, and that conditions differing in their clinical manifestations may be due to infection with one and the same micro-organism. In this section the authors attempt to correlate the findings of those investigators who dealt with small groups of cases of gas gangrene prior to the war with the results that have been obtained by themselves and others from recent more precise inquiries. The authors' criticism of the confusion of thought and carelessness of technique which led in pre-war days to the adoption of a chaotic nomenclature, and caused a falsely simple view to be taken of its causation, is fully justified—von Werdt actually described a disease that did not exist. The danger of drawing conclusions from observations based upon the investigation of impure cultures is insisted upon, and for this section of their monograph alone Weinberg and Séguin lay bacteriologists under a debt of gratitude for evolving order from chaos. This diversity of causal organisms and the natural corollary thereof—symbiosis as a factor in the causation of infection—is for the first time appreciated at its true value. The point is well put on p. 31.

"En définitive, la 'gangrène gazeuse,' malgré son apparente unité, n'est, au point de vue pathogénique, ni *une* maladie ni même un ensemble de 2 ou 3 maladies; c'est un état morbide causé par des flores microbiennes extrêmement variées. A nous en tenir aux seuls anaérobies, nous avons trouvé 40 types de flore pour les 91 cas de gangrène gazeuse que nous avons étudiés.

Le problème de délimitation qui est parfois si délicat pour une maladie monomicrobienne spécifique prend donc ici un caractère de difficulté qui le rend presque insoluble."

The second section, in which is given a systematic description of the micro-organisms that play a part in the causation of the disease under consideration, is of more interest to the laboratory worker than to the general reader. Four new species of bacilli—*B. œdematiens*, *B. fallax*, *B. aerofœtidus*, *B. histolyticus*—which have been isolated for the first time by the authors, are fully described, along with the other organisms that have in past times been incriminated as causal agents of gaseous infections. Of the new species, *B. œdematiens*, both because of its apparently frequent occurrence and of its undoubted pathogenicity, is most carefully considered, and an excellent case is made for regarding it as a separate species altogether from *Vibrion septique*. It is refreshing to find that Weinberg indicates in this section that *B. Welchii* may be a species which comprises several sub-groups and suggests that the same may be true of other anaerobic bacilli which have hitherto been defined by cultural reactions alone. A specially valuable feature of this section are the notes pointing out the relationships which the micro-organisms, that have been recently defined, bear to others that have from time to time been described as of importance in the causation of gas gangrene and kindred conditions both in human and in veterinary pathology.

The third section deals with the origin and evolution of gaseous infection and very pointedly emphasises the importance of diversity of infection, of symbiosis, and what might

well be termed "the life-history of wound infection." Attention is called to the valuable information that may be obtained both by blood culture and by examination of tissue from the site of the lesion, and to the special factors—arising from the conditions under which war wounds are received—that tend to cause gas gangrene, as well as to the physical and other factors which in each individual case are adjuvant to its incidence. Finally, the experimental work which led to the preparation of specific sera is fully described. The results of the employment of Weinberg's sera are most encouraging, and his work has made it possible to place in the hands of surgeons and physicians valuable prophylactic and therapeutic reagents.

Professor Weinberg and his collaborator are to be congratulated on the excellence of this work. The matter is well arranged and the whole work is marked by a concise diction and by a logical sequence of presentation that makes it a pleasure to read. The work is a mine of useful information and of helpful suggestion, while due emphasis is laid upon the valuable results to be obtained from careful bacteriological inquiry.

Treatment and Repair of Nerve Lesions. By Mme. ATHANASSIO-BENISTY, House Physician to the Salpêtrière. Preface by Professor PIERRE MARIE, Member of the Academy of Medicine. Edited with a Preface by E. FARQUHAR BUZZARD, M.D., F.R.C.P., Lieutenant-Colonel, R.A.M.C. With 62 illustrations and 4 full-page plates. 1918. Pp. 181. Price 6*s.* net.

Clinical Forms of Nerve Lesions. By Mme. ATHANASSIO-BENISTY, House Physician to the Salpêtrière. Preface by Professor PIERRE MARIE, Member of the Academy of Medicine. Edited with a Preface by E. FARQUHAR BUZZARD, M.D., F.R.C.P., Lieutenant-Colonel, R.A.M.C. With 81 illustrations and 7 full-page plates. 1918. Pp. 235. Price 6*s.* net.

London: University of London Press, Ltd.

WE have already reviewed these excellent compendiums on the occasion of their original appearance in a French edition. In English form they are sure of wide appreciation as they contain a wealth of practical information, based on war experiences, bearing on the protean forms of nerve injury. Symptomatology, diagnosis, prognosis, and treatment are so fully described as to leave little for criticism by way of omission, and still less by way of inaccuracy of statement. We note that the writer rather favours "hersage" as a suitable form of operative treatment in selected cases—i.e., the making of a series of longitudinal incisions in the nerve over the part injured and deformed by local swelling or neuroma-formation. For causalgia apparently hersage has given a good result in some cases, but alcoholisation rests on a securer basis. The illustrations and diagrams add materially to the usefulness of these text-books, which are essentially up to date, and also contain numerous references to the abundant literature of peripheral nerve injuries. The translation is uniformly well done.

JOURNALS.

The Journal of Comparative Pathology and Therapeutics. Edited by Sir JOHN MCFADYEAN and Sir STEWART STOCKMAN. Edinburgh: W. and A. K. Johnston, Ltd. Price 2*s.* 6*d.* quarterly, or 10*s.* per annum.—The June number of this journal is full of good things for others than veterinarians. In a paper on the Histology of the Lesions of Johne's Disease, by Sir John McFadyean, we have an interesting comparative study of the lesions produced by the bacillus of Johne's disease and of those produced by the bacillus tuberculosis. The observations are of special moment in that, up to a certain point, the Johne's bacillus appears to do all the work that the tubercle bacillus achieves, but at this point it stops short and does not bring about the caseation changes so characteristic of tuberculous lesions in cattle. A further differentiating feature appears to be a lesser faculty—or opportunity—of migration on the part of the Johne's bacillus. Principal McFadyean's observations on the formation of plasma cells, giant cells, and on what he speaks of as the "symplasma" stage will be read with interest and profit by those interested in "bovine" tuberculosis, as well as by those who refer to the paper for its account of the histology of Johne's disease.—J. C. Lewis, D.V.Sc., and N. R. Seddon, B.V.Sc., contribute a suggestive but somewhat inconclusive account of "Habronemic Conjunctivitis."—Two papers, one on Castor-seed (*Ricinus communis*) Poisoning in Horses, by G. H. Wooldridge, F.R.C.V.S., the second on Poisoning of Horses with Castor Seeds, by Munroe White, M.R.C.V.S., deal with the symptoms, treatment, prognosis, and morbid anatomy of what is evidently a very serious matter for horse owners during the present shortage of fodder, when there exists such a temptation to "rope in" additional sources of food. Typical gastro-enteritis, emaciation, and exhaustion appear to characterise this type of poisoning, sometimes accompanied by peculiar neuro-muscular symptoms. One important factor in the treatment is, apparently, absolute rest.—Tuberculosis in the Camel, by Major F. E. Mason, A.V.C., has been studied so little that much of what is here set down is practically new, and both veterinarians and pathologists will look forward to further instalments of Major Mason's interesting observations.—The same may be said to apply to the article on Scrapie, by Sir John McFadyean, who, however, breaks a lance in a friendly joust with Dr. J. P. McGowan, who maintains that scrapie is the result of a heavy infection of the muscular tissue of sheep with sarcosporidia.—A Note on Piroplasmosis of the Donkey, by J. A. Griffiths; a review on Veterinary Post-mortem Technic, by Walter J. Crocker, B.S.A., V.M.D.; and an abstract, Blood-sucking Insects as Transmitters of Anthrax, complete a very readable number.

The American Review of Tuberculosis. Baltimore: National Association for the Study and Prevention of Tuberculosis. Price 35 cents.—The June issue gives a striking insight into the thoroughness with which the campaign against tuberculosis is being carried on by influential bodies in the United States of America. Dr. Donald B. Armstrong, the executive officer of the Framingham Community Health and Tuberculosis Demonstration, describes its working since its initiation in December, 1916. During its first year of existence 5000 persons, representing about one-third of the population of Framingham, were voluntarily examined by experts in a search for incipient or neglected tuberculosis. Summer camp accommodation was found for 100 delicate children, about 500 children between the ages of 1 and 7 years were tested with tuberculin, and about 4000 cases of illness or defects other than tuberculosis were referred to local physicians for treatment. These achievements represent only a fraction of the activities of the Framingham scheme. Were it not that Dr. Armstrong could show this scheme already in full activity, with definite results obtained, this whirlwind campaign of a small community to put its home in sanitary order would read like some Utopian project. It is refreshing to find that in the United States at any rate the health reformer who dreams dreams is sometimes able to translate them into action.—A paper by Dr. Forrest B. Ames describes the results of a tuberculosis survey of the residents of Saranac Lake. A modern village of nearly 6000 inhabitants, it has become a centre for tuberculous invalids, about one-fifth of the total population having immigrated there for their health. The health of the indigenous population was found by the house-to-house canvass to be excellent, in spite of poor housing conditions in certain quarters; and the indigenous morbidity and mortality from tuberculosis were exceptionally low. This paper, which confirms the findings of previous investigations into the health of the indigenous population of tuberculosis health resorts, is crammed with tables and analyses, and is another example of the painstaking methods adopted in America to elucidate the problems of tuberculosis.—A third paper by Dr. Walter L. Rathbun is a plea for a more skilled and systematic search for tuberculosis among incoming aliens.

Archives de Médecine Navales.—Dr. Mourron (Fleet Surgeon) of the French Navy discusses in the issue for July the establishment of sanatoriums for the tuberculous invalids of the French Navy and dockyard services. The navy has already two small sanatoriums on the west coast, but Dr. Mourron thinks that sea air is too stimulating for phthisical cases, and proposes that other sanatoriums be established in the south of France. A recent decree has put £40,000 at the disposal of the French Home Secretary for the providing of hospitals for the men of the navy invalided during the war for bacterial diseases of the lungs; that is why Dr. Mourron is considering this question just now. He assumes it will be necessary to provide three sanatoriums—one of 500 beds for early cases, one of 300 beds for developed cases, and a third of 200 beds for advanced cases. He recommends their location near Toulon, in a sheltered valley at an altitude of about 700 feet, already chosen by the Anti-tuberculosis Society of Toulon as the site of its sanatorium. He estimates the cost of buildings at £200 per bed, while maintenance would require about 4*s.* daily, a total expense of £200,000 for building and £75,000 annually, although it is very difficult to estimate the length of stay of the average patient. This sum is more than has been allotted by Parliament, but Dr. Mourron insists that dockyard men shall be allowed to benefit as well as the sailors, and hopes that the expenditure will, by cures and by education of its patients, well repay the country, the loss by tuberculosis being so heavy. When the cost of cure is so high, might it not be more thrifty to pay more attention to prophylaxis by the more extended application of artificial ventilation in the ships of the Fleet?

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 7, 1918.

Coal and the Cult of the Skin.

MANY times already in the course of the war the medical profession has been invited by Government Departments to use its influence in bringing home to the people at large the hygienic lessons rendered urgent by the times we live in. The most recent of these appeals emanates from the Office of the Coal Controller, who warns us that the country is faced with a serious shortage of coal. The outlook to-day, he says, is much graver than is generally realised, the deficit amounting to something like 36 million tons of coal. Coal is the principal and irreplaceable source of power, whether for offence or defence; it is the raw material from which gas, electricity, and steam alike are produced, and a reduction in its supply beyond a certain limit would put an end to essential industries. The Coal Controller draws the lesson that self-denial is called for, that every private consumer should be content with three-quarters of the ration which is legally his due; and he appeals to medical men to help him in enlisting the services of every man, woman, and child in the country in a united effort of economy in the use of coal. To us it appears that the counsel of the medical man might often be of the first value.

It would be easy to enlarge on the hardships which any further restriction in the already scanty coal-supply will involve for the private citizen. The hardship might indeed imply some danger for the old and infirm as well as for the young child, were it not for the prospect already held out of an increased allowance in respect of both extremes of life. We are concerned here rather with the average citizen and his vital needs. Fuel economy affects us chiefly in two directions. In warmer weather, such as at present prevails, our coal is used to cook and, with a growing mass of the population, to heat water for washing. In the winter, to which the Controller is looking forward with anxiety, coal is used in addition to raise the temperature of the home atmosphere above that of the outside air. Economy of coal in relation to the preparation of food is a familiar subject to those who have studied it practically. And it should now be known to every man, woman, or child that to cook any kind of viands they need only be raised to the required temperature by the active use of fuel, when they can be maintained at or near this level by insulation in one or other of the many ways, of which the newspaper cosy is the cheapest type. Alas! this simple fact, fundamental for economy, appears to be hidden from many people. The continuous consumption of coal or gas throughout the day in a private house for cooking either implies a lamentable want of enterprise or a lack of that feeling for the needs of others enjoined on us by proclamation. The using up of fuel to heat water for bathing purposes continues on an enormous scale. Water is very costly to heat, and this attribute of water makes it an admirable medium for circulating warmth about the house, but there is an obviously large waste of potential energy in allowing successive instalments of 20 gallons each of slightly soapy water at 100° F. to run down the bath-room waste. Nothing is more certain than that the daily full hot bath is unnecessary either for cleanliness or for the maintenance of the proper function of the skin. The frequently repeated use of soap and hot water over the whole body removes from the skin the natural fat which is itself a desirable insulating material. We may admit without shame that the hot-bath habit is in the nature of a pleasant indulgence for those citizens whose ordinary avocations do not bring them into close association with dangerous materials, which have to be regularly removed from the skin by drastic ablution.

Turning to winter conditions, it is in the maintenance of the difference between indoor and outdoor temperature that coal is principally consumed in the private house, and the consumption runs up rapidly as the difference becomes greater. In the summer, when indoor and outdoor temperatures are roughly equal, we wear the same clothes both in and out. As the outdoor temperature falls in autumn most of us temporise by dressing more warmly before resorting to artificial heat. The point at which we give in to the cold varies greatly. In Vladivostok there is little to be gained by delaying the day, since the winter cold is so intense that the resident makes no attempt to meet it half-way, but lives indoors in summer clothes at an artificial summer temperature, encasing himself thickly in the skins of beasts when he stirs abroad. But the climate of this country, much as we abuse it, has this in its favour: that the difference between average summer and winter temperature is only slight, so that the fate of the tuberculous patient or the wounded soldier unprovided with artificial heat is no more to be pitied than that of his comrade in the trenches. Those who think otherwise have not sufficiently realised that the skin is not a mere protective crust but an organ with functions as definite as those of the heart or the kidneys—functions with a wide range of adaptation which develop with appropriate use and respond in proportion to demand. Fortunately, in the recent rise of interest in the maintenance of infant health the public has been receiving object-lessons of the first value along these very lines. Skin training, as we know, plays a large part in the education of the infant, and in the modern nursery the judicious use of cold water and of friction leads on to an indifference to the impact of cold air currents and an absence of that sensitiveness which is a nuisance to its owner and a serious handicap in the business of life. "I am cold but not suffering," is the expression of one so trained. It is perhaps unfortunate that the sensations of heat and cold should have any agreeable or disagreeable tone attached to them. The surface

temperature of hands and feet varies greatly in different people, the same temperature to some being a discomfort, while to others it is a matter of indifference. The sensation of heat and cold provoked in the skin is doubtless a physiological response designed, like that of pain, to call attention to the need for adjustment. But the sensation of cold is largely influenced by the condition in which the skin is maintained. If its possessor keeps it in a more or less moist and sodden condition, at the same time carefully removing the natural non-conducting fatty material, heat is transmitted freely through it, and the need is felt for more external warmth. The pampered skin becomes ever more imperious in its demands. It should be borne in mind that each one of us lives, not so much in the climate of the town or even of his house, but in the atmosphere within his own clothes.

We do not suggest that every individual should study the functions of his skin, seeking to discover for himself the limits of compensation within the bounds of safety. But we think that medical men may be of the greatest assistance to their charges by explaining to them that sensations of cold which they find disagreeable can be largely mitigated by common-sense precautions, and will tend to disappear spontaneously when regarded rightly. Sir GUY CALTHROP'S appeal to the public to save coal may prove, as a secondary result, a stimulus to domestic hygiene of the first order. Many will thereby escape from a yoke of which they are almost unaware.

The Names of Diseases.

ACCURATE nomenclature and an understanding of the principles upon which nomenclature is based are of fundamental importance in the progress of any exact science, and although the science of diseases cannot claim to be exact in the same sense as mathematics, its progress, like that of other sciences, depends largely upon the uniformity, consistency, and accuracy with which its terms are employed. For statistical purposes it is essential that the names of diseases should convey the same meaning to all who are engaged in observing and recording them. Multiplicity of names for one and the same disease must lead to confusion, and any lists of diseases should consist of short names comprised in one word, or in the fewest possible words, the names being such as are in common use which yet do not imply erroneous or doubtful theories. The name of a disease should connote its etiology, its general or local site, its characteristic symptoms and physical signs, and the pathological effects which it produces in organs and tissues. But these conditions cannot be satisfied in every case. In some the etiology is unknown, in others the localisation; in some the symptoms and physical signs are not distinctive, in others the pathological consequences on organs and tissues may not be perceptible; in others, again, these morbid changes are all we have to guide us. A nomenclature of diseases cannot therefore avoid including the names of symptoms and physical signs and morbid changes. But symptoms and physical signs are not themselves diseases, and their names should not be used to connote disease when further information is available. The object of a national nomenclature is not educational or dictatorial, it is merely to record and to stereotype for the time being names which are in common use. It is not the compilers' business to alter or correct such names or to invent new ones. Hence, the compilers of a nomenclature are not to blame for including names sanctioned by antiquity although they have long lost their first significance, or names which shock the purist on account of their hybrid and barbarous formation. If generally accepted by medical writers they are retained, if obsolete or becoming so, they are dropped out, or used only as synonyms; their coming and going affording valuable landmarks in the history of medicine.

Classification is of equal importance to indicate the relationship between the diseases and conditions named. Theoretically diseases might be classified according to their symptoms, their causes, their intimate nature, according to the tissues or the systems of the body affected, or according to the parts of the body as they lie anatomically. In the present state of our knowledge the best classification is topographical, diseases being divided into those which affect the body as a whole, and those which affect locally different systems, and the organs and tissues of which they are composed. This method of classification was adopted by the joint committee appointed by the Royal College of Physicians of London which drew up the first Nomenclature of Diseases in 1869, and the compilers of the fifth edition just published have not departed from the general principle. The changes in the new edition are not of a drastic nature. The section hitherto entitled Infective Diseases is now described as Diseases caused by Infection. Intoxications have been relegated to the list of poisons in the appendix. More significant is the splitting up of a heterogeneous collection of diseases called "general" in former issues into three new groups: Diseases of the Blood, Diseases of the Ductless or Endocrine Glands, and Diseases due to Disorders of Nutrition or of Metabolism. While this spells progress there yet remains, to remind us of our ignorance, a large group of disorders classified as "Names of symptoms, groups of symptoms, diseases named with reference to their symptoms, and diseases of which the pathogenesis is not accurately known." And although this tell-tale heading occurs in all sections, it is especially well represented in that of diseases of the nervous system. Under the broad topographical headings subdivision has been carried out on a definite scheme in so far as it applies to individual organs and structures, the sub-headings being—

(1) Inflammation and its varieties; (2) vascular conditions—hyperæmia, hæmorrhage, anæmia, œdema, thrombosis, embolism, necrosis, gangrene; (3) hypertrophy and atrophy; (4) local manifestations of general diseases, such as syphilis, tuberculosis; (5) diseases and disorders of function special to the organ under consideration; (6) local nervous affections

such as atony, spasm, paralysis; (7) degenerations; (8) mechanical results of diseases; (9) cysts and new growths, non-malignant, malignant; (10) effects of parasites; (11) effects of poisons; (12) malformations; (13) injuries; (14) foreign bodies.

Varieties or special forms of diseases are usually indented below main headings; but indented names do not necessarily include all forms of the heading under which they are indented.

Where synonyms must be given, the name of the disease which appears first is that by which it is usually known. The synonym is the Greek, Latin, or English equivalent, and in making a return it is optional to employ the name of the disease which appears first, or its synonym. The compilers of the Nomenclature have decided to omit in this edition the triple column of Latin, French, and German equivalents or translations which formed a prominent feature in previous editions. Their decision, which some may regret, was based principally on the logical ground that the insertion of French and German names was beyond the scope of a British nomenclature. The ambition of the first compilers to be the founders of a truly international nomenclature has not been realised, and, except by international agreement, it is obviously impossible to guarantee the correctness of the foreign equivalents. The omission of Latin and Greek equivalents was dictated by other reasons. The former are often mere translations of English phrases, while many of the names of diseases in common use are already framed upon a Latin or Greek basis, or are hybrid combinations sanctioned by time. No real need therefore exists for a separate Latin column. In so far as the omissions make for simplification they are entirely to the good, and will conduce to the general use of the Nomenclature of Diseases by all medical practitioners for the registration of diseases. It is to be hoped that in its present simplified form the book will be in more frequent use as a work of reference. It not infrequently happens that a medical practitioner having to fill up a death certificate is at a loss in what form to state the primary cause, and for this purpose the Nomenclature should be of great assistance. Uniformity in the return of causes of disease is essential for statistical purposes, and without accurate statistics no effective control can be exerted on the public health.

We have received a copy of the report of the Committee of the Privy Council for Scientific and Industrial Research for the year 1917–18. This is the third annual report issued since the committee was appointed. The past year has seen a great extension of the work of the department, to some of the salient features of which we propose to return in a future number.

WE regret to announce the death in a London nursing home of Dr. Margaret Todd, sometime medical officer to the Edinburgh Hospital for Women and Children, and best known as a writer under the pseudonym "Graham Travers."

THE death occurred at Birmingham on August 28th, in his sixty-ninth year, of Dr. Robert Saundby, emeritus professor of medicine in the University of Birmingham and consulting physician to the General Hospital, well known alike as a clinician, teacher, administrator, and author. We hope to give some account later of his fruitful and many-sided activities.

Annotations.

"Ne quid nimis."

MOTHERHOOD AND INDUSTRY.

THE employment of married women on a vast scale in munition factories has recently created what is largely a new problem in industrial hygiene. The problem is not entirely new, for in the manufacturing centres of the North of England many women have been accustomed to factory work for the greater part of their lives, and in Dundee the Census returns for the year 1911 show that more than 40 per cent. of the married women in the town between the ages of 20 and 24 were occupied before the war in remunerative occupation outside their homes. In Dundee, as we learn from the pages of the Carnegie Report[1] on Scottish Mothers and Children, married women's labour has long been recognised as a contributory cause to an abnormally high infant death-rate and stillbirth-rate. The report of the medical officer of health, Dr. Charles Templeman, for the year 1905 showed that more than half the employed mothers in Dundee worked up to within two months of their confinement, and a special inquiry conducted for the Scottish Insurance Commissioners in 1904 by Miss Mary M. Paterson revealed the further fact that while many women were sent away from the mill some time before childbirth, because their work failed to reach the required standard, it was often only a change to laborious work elsewhere or at home.

But the larger problem is new, since it is only during the war that any considerable proportion of women have entered upon factory employment or that many places have been filled by married women; some of whom have offered themselves doubtless in view of the urgent national need, others on the more usual ground of supporting themselves and their children. In the second of two inquiries made by Dr. Janet M. Campbell into the health of women munition workers, a large proportion of married women were found among the 1183 women examined in eight typical factories, and many of them were employed on heavy work. Dr. Campbell in her report on this inquiry to the Health of Munition Workers Committee[2] touches on some of the difficulties of these women in regard to the most important events of their lives. The married women with homes of their own, she tells us, generally leave the factory in the early months of pregnancy, but a number of others are obliged by financial pressure to work almost up to the time of confinement. In filling factories it is the usual practice to discharge a woman as soon as she is known to be pregnant, and the fear of dismissal may lead her to conceal her condition as long as she can, with results which may well be disastrous to both mother and child. The expectant mother, as might have been anticipated, does not fit smoothly into the rigid industrial routine originally planned for the male worker, and cannot take her place safely in the open labour market.

Expectant motherhood should, many people think, be excluded altogether from the stress of industrial life, and it is instructive, therefore, to note the experience of those who can show good reason

[1] Report on the Physical Welfare of Mothers and Children, Part 2, Scotland, 1917.

[2] Final Report on Industrial Health and Efficiency. 1918. Cd. 9065. Price 2s.

for holding the contrary view. We publish this week part of a report to the Oxford Welfare Conference by Dr. Mary A. S. Deacon dealing with the effect of employment in a filling factory on 1200 women workers over a period of nine months. Of the 575 married women among them more than one-sixth became pregnant during this time, and of these 101 pregnancies so far 65 went on to full term without mishap, 2 terminated prematurely on account of cancer in the one case and syphilis in the other, while 13 abortions occurred before the third month was completed. Mrs. Deacon discusses the employment of these expectant mothers both from the employers' point of view—the efficiency of their work—and from the workers' point of view—the question of maternal welfare. She assumes the necessity of such work under present war circumstances, and endeavours to bring about conditions satisfactory alike to employer and expectant mother. Fortunately, in a filling factory work is graded, and in many cases she found it possible to obtain the temporary transference of pregnant workers from the heavier to lighter operations. In other kinds of factories where such grading is not possible the expectant mothers may be provided with a pre-maternity work-room under the supervision of the factory medical officers, a suggestion made by Dr. Rhoda Adamson[3] from her experience as medical examiner of the National Ordnance Factories in Leeds. Further light on these points will be very welcome in view of the conclusion reached by Mrs. Boyd Dawson,[4] in a recent report on industry and motherhood made over a wide field, that given good food and hygienic conditions there is little, if any, evidence of harm accruing to women from occupations involving severe muscular labour. "We can find no case," Mrs. Dawson writes, "on the grounds of quality of maternity, for the prohibition of any woman to undertake any kind of healthy employment of which she feels herself capable." Here is a fruitful object of study for the scientific factory surgeon.

REMOVAL OF A PROJECTILE FROM THE CAVITY OF THE LEFT VENTRICLE.

AT a meeting of the Académie de Médecine of Paris on August 6th M. René Le Fort reported another case of a remarkable advance made in French surgery during the war—the removal of foreign bodies from the cavities of the heart. This appears to be the first case on record of removal of a foreign body from the cavity of the left ventricle. The history of the patient, whom he showed, was briefly as follows :—

A man, aged 21 years, was wounded on Sept. 21st, 1917, at Verdun, by a grenade fragment which passed through his right arm and penetrated his chest. His initial troubles were hæmoptysis and right hæmothorax from which he quickly recovered. But the projectile, which was described as "intrapericardiac," remained. He suffered from dyspnœa on exertion and cardiac irritability, and could not work. The radioscopic report was that the projectile was situated at the apex of the heart and moved with it. In July, 1918, he came under the care of M. Le Fort, who made an incision in the fifth intercostal space, divided the fifth costal cartilage, turned back the pleura adherent to the pericardium, and opened the pericardium, which contained citrine liquid. Radioscopy showed clearly that the projectile was in the heart. With the gloved hand it could not be felt, but on removing the glove a sensation of altered contour could be felt near the apex. The intercostal incision was transformed into a "hinged shutter," comprising the fourth and fifth ribs. An attempt was made to hold the projectile near the apex while four fine double sutures of silk were passed with a curved needle, confining the projectile. The ventricle was incised at the apex, a grooved director was passed into it, and the projectile, which appeared to be entangled in the chordæ tendineæ, was gently loosened and removed with Kocher's forceps. The four sutures were tied, but one of them broke.* When the heart was set free a jet of blood squirted out to a height of more than 1½ metres. The hæmorrhage was arrested by passing two more sutures. The pericardium was first sutured, and then the thoracic wall in three layers without drainage. The operation at first accelerated the heart's action, but this was considerably slowed at the time of incising the ventricle. The beats fell below 30 for one or two minutes, and then rapidly rose to 56. The respiration momentarily stopped on incising the heart, and the face paled. When the patient was put back to bed the face and lips had lost colour, but this was regained in a few hours. Recovery was uninterrupted. The grenade fragment measured 8 by 4 by 4 mm., and was encrusted with a fragment of endocardium.

Most of the projectiles removed from the heart up to the present were imbedded in its walls. In only 5 of the cases recorded previously by French surgeons was the projectile removed from one of the cavities, and always from the right side—once from the auricle and four times from the ventricle. M. Le Fort has removed 11 foreign bodies from the heart in the course of nine operations—in two cases from cavities of the heart. Only one patient succumbed; all the others were cured.

PULMONARY TUBERCULOSIS AND PREGNANCY.

ALTHOUGH very many contributions to the reciprocal effects of pregnancy occurring in the subjects of pulmonary tuberculosis have been published it is still true that our actual knowledge of the subject remains very imperfect. In respect of active treatment the only conclusion deducible by an unprejudiced student of the literature is simply that each case must be judged individually. A recent investigation by Dr. Th. Begtrup-Hansen[1] affords some new facts of importance. Based on his extensive Scandinavian experience, Dr. Begtrup-Hansen summarises his researches somewhat as follows:—

The clinical material numbered 214 patients—59 from consumption hospitals, 60 from sanatoria, and 95 from lying-in institutions, while an additional 85 cases were gathered from the literature. The material for study was thus fairly eclectic. The first point of inquiry was as to the period of pregnancy at which phthisis appeared or became aggravated, and it is stated that the first symptoms of such were referred by more than half the patients to the first three months. 20 per cent. named the second three months, 16 per cent. the third, and only 4 per cent. specified the puerperium itself; with this anamnesis the results of physical examination tallied very well. When the disease appeared early—i.e., in the first half of pregnancy, its course was distinctly favourable, as shown by decline in temperature, decrease of chest symptoms, but most by pronounced increase in weight. This improvement was most noticeable in hospital and sanatorium, and occurred in all stages of the disease. Puerperal phthisis, on the other hand, behaved altogether differently; 60 per cent. of its subjects got worse, and nearly a third of them died. There were thus, the author concludes, three different phases of tuberculosis in pregnancy. In the first half a critical period with increased vulnerability, then a time of increased resistance in the second half, and, finally, at the puerperium a critical period of grave import. He attempts to explain these findings in what is perhaps a rather roundabout way, relating them with variations of body temperature. Before menstruation the temperature fluctuates and is raised, while it falls during and after the period. During pregnancy the temperature is of pre-menstrual type for the first three or four months and of post-menstrual for the latter half. At the puerperium it is first pre- and then post-menstrual.

If these generalisations are granted the epochs of pre-menstrual type of temperature coincide with the critical epochs of vulnerability to tubercle. Referring to a previous work, the

[3] Maternity and Child Welfare, March, 1918.
[4] The Women's Industrial News, July, 1918.

[1] Internationales Centralblatt für die gesamte Tuberkulose-Forschung, April, 1918.

author explains these temperature fluctuations as due to variations in albumin metabolism, which he found at its height in the first half of pregnancy and in the first week of the puerperium. Finally, the conclusion as regards therapeusis is that conservative treatment in a sanatorium is to be tried in all cases during pregnancy and also after delivery, and that there is no general indication for practising artificial abortion. For this last measure each case, as, indeed, we had surmised, must be judged on individual grounds.

SYSTEMATIC INSTRUCTION IN WAR NEUROSES.

A FIRST course of instruction in shell shock and war neuroses held at the Maudsley Neurological Clearing Hospital having proved successful, with a good attendance of both military and civilian practitioners, the Director-General, A.M.S., has given his approval to a systematic course, extending over three months, which will commence on Sept. 20th. Daily instruction and practice in diagnosis and treatment will be given each weekday, Saturday excepted, from 10 A.M.–12.30 P.M., and from 2–4 P.M.; systematic lectures with demonstrations of illustrative cases on Tuesdays and Fridays at 3 P.M. The syllabus will cover:—

1. The anatomy, physiology, and pathology of the nervous and muscular systems applied to the diagnosis, prognosis, and treatment of shell shock and war neuroses.
2. The physiological and pathological conditions underlying shock—emotional, commotional, and surgical.
3. The methods of examining cases of functional nervous disorders (hysteria, neurasthenia, and psychoses) and the determination of fitness for military service.
4. The methods of differential diagnosis of organic and functional disease and the combined conditions.
5. The diagnosis of conscious simulation (malingering), unconscious simulation, and exaggeration.
6. The general principles of treatment of functional diseases of the nervous system.
7. General aspect of the surgical side of neuro-muscular disabilities.
8. General principles of psychology as applied to war neuroses and shell shock.

The course will be open to all officers in British, Colonial, and American medical services; also to civilian practitioners presenting a letter of introduction from a physician or surgeon attached to a university or hospital medical school. No fees will be charged. Applications should be made to Lieutenant-Colonel F. W. Mott, R.A.M.C., Maudsley Neurological Clearing Hospital, Denmark-hill, London, S.E. 5, who will submit them to the Director-General.

A NEW EMPYEMA TECHNIQUE.

SURGICAL drainage is carried out whenever possible from the most dependent part of a body cavity, but in the case of empyema it is often by no means easy to determine by physical signs the site for incision in order to have gravity entirely in favour of the operator. In the *Military Surgeon* for July, First Lieutenant Thomas R. Sealy, M.R.C., suggests a simple and ingenious technique for discovering the size and shape of an empyema before operation. Having aspirated what pus he can and accurately measured the volume drawn off, he injects through the not-withdrawn needle an exactly equal volume of a mixture of saturated boric lotion with an equal part of mucilage of acacia containing 10 per cent. of barium sulphate or carbonate in suspension. The patient is then at once X rayed, the outline of the empyema is defined, and the chest opened at what is now definitely known to be the most dependent point. In actual practice we believe that several considerations may limit the value of this procedure. In the first place, patients with empyema lie in bed, and the part of the pleural cavity most dependent in the erect position will not be so in the recumbent. Then the empyema patient generally lies on the affected side in order to give the healthy lung more play, making drainage easy wherever the opening is situated. Further, it must not be forgotten that when the cavity of an empyema has been emptied the space left is filled in part by the expansion of the lung, in part, especially in children, by the falling in of the chest wall, and in part by the rising of the diaphragm. An opening made at the most dependent part of the pleura may soon become blocked by the ascent of the diaphragm. Surgeons will, however, find it worth while to bear in mind Lieutenant Sealy's plan.

CAUSES OF DEATH AND INVALIDITY IN AUSTRALIA

THE committee appointed by the Australian Government to report on the causes of death and invalidity in the Commonwealth have brought in their final report.[1] Several of the "progress reports" issued at intervals during the last two years have been noticed in our columns on their appearance. The terms of reference to the committee were briefly as follows: (1) the collection of evidence as to causes of death and invalidity; (2) the indication of suitable measures for their investigation and prevention. The control of public health legislation in Australia at present rests mainly with the Parliaments of the several States, upon whom devolves the duty of maintaining locally an effective Public Health Service. The unit of health administration is the council of each municipality. We are not surprised to learn from the report that the "linking up" of these practically autonomous and independent local authorities leaves much to be desired, and that even where a highly qualified permanent official has been appointed locally he too often lacks competent assistance as well as adequate executive powers. In these circumstances it may well be that the Commonwealth Government would benefit by the experience of the mother country. It has been long recognised in England that, in order to secure the satisfactory discharge of public health functions by widely scattered local municipalities, a coördinating central authority armed with adequate statutory powers is essential. From the present report we gather that the Government of the Commonwealth takes a similar view. It has already assumed, experimentally, certain functions of a preventive character, and, in particular, has committed itself to a rôle of general responsibility, with respect to the maintenance of public health in Australia. In the judgment of the committee there should be, in each State, a competent Minister of Health, each State being divided into districts under the supervision of a medical inspector, responsible only to the supreme authority. The appointment of medical officers of health should be subject to the approval of the same authority, and no medical or other health officer should be removable without that authority's approval. The committee insist that some such organisation as the foregoing is absolutely necessary for progress. All the authorities, central as well as local, must rise to new ideals as to what is implied in the expression "public health." Far from being limited to a merely perfunctory performance of scavenging services, or even to the development of

[1] No. 73. F. 10573. Government Printers, Victoria. Price 3d.

ordinary preventive measures, a public health organisation worthy of the name should mean—in the words of the report—

"The uplifting of the life of the people to new levels, where a robust race would work out its destiny, with the comfort and happiness that are only possible in a well-organised, well-administered State."

Valuable service could be rendered by the Commonwealth in the attempt to secure uniformity in the State health laws and in their administration, in the systematic collection of sanitary data, and in the promotion of health research. Great impetus would be given to progress if the Government would contribute to the cost of appointing medical inspectors throughout Australia, and would invite, at its own expense, an annual conference of the health officers of the several States with the Director of Quarantine. The report is ably compiled, and is signed by three physicians and countersigned by the chairman, Mr. James Mathews, M.P.

WAR-TIME LINIMENTS AND OINTMENTS.

WE referred last week to the Codex Addendum published in the *Pharmaceutical Journal* of August 31st, in which are set out the alternative formulæ for preparations containing lard or vegetable oils, modified in or withdrawn from the British Pharmacopœia, 1914. The addendum, which is published under the direction and by the authority of the Pharmaceutical Society, which alone is responsible for the formulæ and for the publication of them, has been prepared under the auspices of the Scientific Advisory Committee by the Pharmaceutical Society's Codex Subcommittee. We understand that the Home Office Committee appointed in August, 1914, to deal with questions of economy in the use of drugs, propose to draw the attention of the medical profession to these war emergency formulæ in a memorandum which they are issuing on the subject of economy in the use of the substances in question and preparations hitherto containing them. The lard substitute (adeps factitius) is made up as follows: wool fat, 5; hard paraffin, 10; soft paraffin white, 85. Liniment of camphor is made with yellow liquid paraffin, and the other liniments containing liniment of camphor are chloroform, mercury, turpentine, and acetic acid. The liquor cresol saponatus is made up of cresol 50·00 (by weight), linseed oil (by weight) 18·00, potassium hydroxide 4·25, and distilled water by weight to 100 parts. Lard substitute is used in adeps benzoatus, unguenta aconitinæ, atropinæ, cocainæ, iodoformi, and lanæ compositum. Benzoated lard made from lard substitute is suitable for the following unguenta: viz., cantharidini, gallæ, hydrargyri ammoniati, hydrargyri iodidi rubri, hydrargyri oleati, hydrargyri subchloridi, myrobalani, plumbi iodidi, potassii iodidi, staphisagriæ, sulphuris and zinci. No alternative is suggested for ung. hydrargyri nitratis. Lard substitute is also used in the following unguenta: Belladonna, capsicum, mercury (metallic), compound mercury, iodine, and resin. Lastly, tar ointment is made with tar 70 parts, yellow soft paraffin 5 parts, and yellow beeswax 25 parts. The Codex Revision Subcommittee, assisted by two representatives of the Drug Club, may be congratulated on arriving at the above war emergency formulæ, which are generally regarded as quite satisfactory.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Health of Belfast in 1917.

FROM the report of the health of Belfast during 1917, just published, it appears that the Registrar-General estimated the population as 393,000, as against 389,000 in 1916; while the medical officer of health's estimate is 404,115. Under these circumstances, the death-rate of 16·7 per 1000—calculated on the Registrar-General's figures—though equal to the lowest on record, may be even better than it looks. For the 10 years 1907–16, the average death-rate was 18·5. The number of deaths in 1917 was 6557, while the number of births was 8718, giving a natural increase of 2161. The birth-rate continues to fall, being 22·2, while in 1916 it was 24·1. The two unsatisfactory features of the report are the infantile mortality rate, which was 130 per 1000 births, an increase of 17 per 1000 as compared with 1916, and the tuberculosis mortality. Consumption (pulmonary tuberculosis) caused 932 deaths, and other forms of tuberculosis 311. The deaths from consumption show an increase of 102—or more than 12 per cent.—upon 1916, and the total is the highest for the last 11 years. Considering that for some years past more than £30,000 a year has been spent in combating tuberculosis by the City Council of Belfast, the return to the bad times of 20 years ago as regards the incidence of this preventable disease is anything but satisfactory. The weak spot in the maternal and child welfare scheme is the absence of a pre-natal clinic and of provision for maternity treatment.

Ulster Medical Society.

On August 19th, at a meeting of the Ulster Medical Society held in the Medical Institute, Belfast (the President, Dr. W. D. Donnan, in the chair), Major A. Trêves, a French surgeon, gave an interesting account of the steps taken to specialise orthopædic work in France. He emphasised the difference between good and bad amputations, and pointed out that the education of maimed men should be taken in hand as soon as their wounds were healed, and the men convinced that they were still able to work. It had specially to be borne in mind that, as far as France was concerned, 70 per cent. of the soldiers came from country districts and not from cities. Although about 25 per cent. of the maimed were not able to perform the work in which they had been engaged before the war, only 4 or 5 per cent. actually went home saying they would work no more. Major Trêves described fully the methods employed in special workshops in France in teaching men to adapt themselves to other employments. To men requiring artificial limbs he recommended that two appliances should be given when they went home, so that if anything went wrong with one limb they had the other to fall back upon. Special films showing the manufacture of artificial limbs were exhibited and their use in agriculture and carpentry demonstrated. The lecture was much appreciated.

Poor-law Medical Officers' Salaries.

The forced strike of dispensary doctors of the Omagh (co. Tyrone) Union continues, and so far there has been no attendance at the Beragh, Fintona, or Omagh Dispensaries; although it is stated a number of dispensary patients attended, the dispensaries remained closed. The lay press is urging dispensary doctors and boards of guardians "to put their heads together and by mutual good sense to find a reasonable way out of the difficulty" that at present exists in reference to the question of salaries. The whole matter is surely capable of friendly adjustment, but hard-worked dispensary doctors cannot be expected to continue—with the present increased price of living—to do their onerous duties at the pre-war salaries. It is instructive to note that only some £5 10*s.* out of every £100 of salary is paid from the rates, the rest coming from such sources as the Treasury grant under the Probate Duties Act, 1888, and the agricultural grant from the Consolidated Fund under the Local Government Act of 1898. In May of this year it was decided unanimously, at a large meeting of the medical profession held in Dublin, to ask all boards of guardians to make the initial salary for every dispensary £200, rising in 15 years to £300. By a little give and take on both sides this question of the payment of Poor-law medical

officers, which is growing in intensity, might soon be settled. As an earnest of better things the Limavady guardians at a specially convened meeting on August 26th decided to grant to the dispensary doctors increases of £25 per annum.

August 30th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Instruction of Temporary I.M.S. Officers.

A NEW Government school has been opened at Rawalpindi under the command of Major C. Hudson, I.M.S., for the instruction of temporary officers of the Indian Medical Service. The school has three sessions in the year—May 1st to July 21st, Oct. 1st to Dec. 31st, and Jan. 5th to April 14th. All temporary officers will join the school in the first instance, and those already employed will undergo a course of instruction when they can be spared. The syllabus will include discipline, military organisation, practical work in military hospitals, the duties of regimental medical officers and medical units in the field, and also principles of tactics. There will, further, be courses of instruction in military hygiene, practical sanitation, and demonstrations. At the conclusion of each session the students will visit the War and Mayo Hospitals at Lahore and medical institutions at Dehra Dun.

Indore Plague Conference.

At a conference recently called at Indore, Central India, to consider the measures for dealing with plague, attended by the medical officers of the Central Indian States, the following resolutions were agreed to:—

1. That when human or rat plague is present, inoculation of the community with plague vaccine and the vacation of infected dwellings result in a very great saving of life.
2. That vacation of infected dwellings should only be encouraged after arrangements have been made for the temporary housing of the refugees near the town or village site.
3. That uncontrolled evacuation, resulting in the invasion of uninfected localities by numerous plague refugees, may be productive of much harm, and the village and town communities do well in their own interests to afford such people a cold welcome.
4. That organised quarantine measures and the inspection of railway passengers are not recommended.
5. That certain forms of merchandise, especially grain, afford facilities for the transference of rats and rat fleas over long distances, and are more dangerous as vehicles of plague infection than the human being.

The conference was an important one, and attended by the Sanitary Commissioner with the Government of India.

Poisoning in India.

The annual report of the Chemical Examiner to the Government shows that 211 cases of suspected poisoning were submitted to the department last year for investigation, as against 197 cases in 1916. In 124 cases no poison was detected, but in some of these the viscera were already highly decomposed. Poison was detected in 87 cases, the principal poisons found being arsenic, mercury, aconite, and powdered glass. In the United and Central Provinces cases of suspected human poisoning showed a decrease to 367, having numbered 459 and 541 in the preceding two years.

Indigenous Medicine Systems.

The eighth annual session of the All-India Ayurvedic and Unani Tibbi Conference was held at Bombay, with a large gathering of delegates. The Maharaja of Gwalior was a visitor. The Medical Registration Act is regarded as endangering the very existence of practitioners of Indian medical science, and the conference aims at popularising the indigenous system of medicine and producing qualified practitioners of it. The conference claims to have awakened a sense of responsibility among the native practitioners. Medical halls have been opened with approved methods.

New Tuberculosis Sanatorium for Bombay.

The Western Indian Turf Club has given a donation of two lakhs of rupees (£13,000) to the King George Anti-Tuberculosis League for the establishment of a sanatorium and hospital. The Bombay corporation has made grants to the league, and property has been acquired for the erection of the necessary buildings.

August 3rd.

The War.

THE CASUALTY LIST.

THE following medical officers appear among the casualties announced since our last issue:—

Killed.

Capt. J. Jaffé, R.A.M.C., attached Somerset Light Infantry, qualified at Aberdeen in 1913, and prior to joining up was in practice at Uitenhage, Cape Province, South Africa.

Major B. C. Tennent, M.C. and bar, R.A.M.C., was educated at Edinburgh, and qualified in 1910. He held appointments at the Great Northern Central Hospital, London, and at the Great Ormond-street Children's Hospital, London, and afterwards practised in New Zealand. On the outbreak of war he returned to this country, and joined the R.A.M.C. in January, 1915. The award of the M.C. and of the bar were recorded in THE LANCET respectively of Sept. 1st, 1917, p. 361, and of Jan. 12th, 1918, p. 78.

Capt. K. W. Jones, D.S.O., R.A.M.C., qualified at Dublin in 1901. He held appointments at the Swansea General and Eye Hospital, and at the Cork-street Fever Hospital, Dublin, and was in practice in Manchester prior to joining up. The award of the D.S.O. was recorded in THE LANCET of Sept. 11th, 1915, p. 628.

Died of Wounds.

Capt. J. S. Wilson, Australian A.M.C.
Major J. Wells, Australian A.M.C.
Major J. Proctor, R.A.M.C.

Accidentally Drowned.

Lieut.-Col. R. H. Bridges, D.S.O., R.A.M.C., was a student at St. Thomas's Hospital, London, and qualified in 1902. Shortly afterwards he joined the R.A.M.C. The award of the D.S.O. was recorded in THE LANCET of June 7th, 1917, p. 894.

Previously Reported Wounded, now Reported Died.

Capt. T. St.L. Leyshon, South African M.C., received his medical education at the London Hospital and qualified in 1906. Prior to joining the South African contingent he was in practice at Knysna, Cape Province, S.A.

Wounded.

Major F. Ellis, M.C., R.A.M.C.
Lieut. S. B. Turner, R.A.M.C., attached Royal Sussex Regt.
Capt. J. V. Duhig, Australian A.M.C.
Capt. L. M. Pigott, Australian A.M.C.
Capt. J. C. McCullough, Canadian A.M.C.
Capt. J. A. MacKenzie, Canadian A.M.C.
Capt. J. C. Eager, Canadian A.M.C.
Lieut. I. Feldman, R.A.M.C., attached Hussars.
Major F. E. Feilden, R.A.M.C.
Lieut. G. F. Rigden, R.A.M.C., attached Lancs Fusiliers.
Capt. G. S. Douglas, R.A.M.C., attached Hussars.
Capt. Q. V. B. Wallace, M.C., R.A.M.C., attd. Tank Corps.
Capt. S. A. W. Munro, M.C., R.A.M.C., attd. Seaforth High.
Capt. D. R. Wark, Canadian A.M.C.
Capt. T. Warner, R.A.M.C.
Lieut. E. Cansfield, R.A.M.C., attached Border Regiment.
Capt. H. C. Trumble, Australian A.M.C.
Maj. A. D. Stirling, D.S.O., R.A.M.C.
Lieut.-Col. A. H. Habgood, D.S.O., R.A.M.C.
Major A. G. S. Wallace, M.C., R.A.M.C.
Capt. J. S. MacKay, M.C., Australian A.M.C.
Major C. R. Merrilees, Australian A.M.C.

Previously reported Missing, now reported Prisoners in German Hands.

Capt. M. Donaldson, R.A.M.C.
Capt. J. A. Gilfillan, R.A.M.C.
Col. A. Milne-Thompson, C.M.G., M.C., R.A.M.C.
Capt. E. H. Jones, R.A.M.C.
Capt. D. M. Smith, R.A.M.C., attd. Northampton Regiment.
Major A. M. Wood, R.A.M.C.

PERMISSION has been granted to Dr. Jessie Anne Scott to wear the Insignia of the Fourth Class of the Order of St. Sava, conferred by the King of Serbia, in recognition of her services as surgeon at the Scottish Women's Hospital at Ostrovo.

THE Local Government Board and the Ministry of Labour have given their adhesion to a scheme set forth in Circular 103 of the Ministry of Pensions, to give disabled officers and men a preference for temporary vacancies now arising in the service of the State. A committee of the Ministry of Pensions is considering the question of the further employment of such men, subject to the reinstatement of former officials now on active war service.

OBITUARY OF THE WAR.

ROBERT CARMICHAEL ROGERS, M.A., M.B., CH.B. EDIN.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain R. C. Rogers, who died of wounds on August 2nd, at the age of 28, was eldest son of D. Rogers, of Murthly, Perthshire. He was educated at Perth Academy, going on to Edinburgh University, where he graduated M.A. in 1910, and M.B., Ch.B. in 1914. After a house appointment at the Royal Infirmary he went into practice in Mid-Calder. In 1916 he received a commission in the R.A.M.C., and early next year went to France as M.O. to the Royal Garrison Artillery. He was wounded in an air-raid last September, and after more than 10 months of suffering, bravely borne in hospital in France, he finally succumbed to his wounds. Captain Rogers married Mary F. Grant, of Kingussie, in 1915, and leaves a widow and one child.

JOHN CAMERON THOMSON TEGGART, M.B., CH.B. GLASG.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain J. C. T. Teggart, who was killed in action on July 21st, was younger twin son of Hamilton Teggart, of Glasgow. He graduated M.B., Ch.B. at Glasgow University in 1912 and then for 18 months held appointments as house surgeon in the Western Infirmary and in the Royal Hospital for Sick Children, Glasgow. When war broke out he was resident surgeon at Johannesburg Hospital, resigning this appointment in 1915 to take a commission in the R.A.M.C. Attached to an artillery brigade, he saw many of the principal engagements on the Western front during a period of three years. He was doing his work amongst wounded gunners during a battle when he was killed instantaneously. His commanding officer writes that Captain Teggart was a capable hardworking officer, whose pluck and keenness were well known throughout the division. "He always shone in positions of danger where initiative and true courage were essential."

Captain ROY ALLAN SILLAR, A.A.M.C., who was accidentally killed on June 30th by a fall from his horse, was a native of Dubbo, N.S.W. Matriculating at 16 years of age, he entered St. Andrews College, Sydney University, and did well both in his medical studies and in the athletic field. After completing his medical course he was resident M.O. at St. Vincent's Hospital, Darlinghurst, and for a few months visiting M.O. at the Women's Hospital there. He enlisted in the A.I.F. at the end of 1917, and in April, 1918, reached England, where he was posted to No. 4 Command Depôt. An officer of Captain Sillar's unit speaks of his strong personality and his bright and sunny nature, which won the hearts of all with whom he came in contact.

WALTER HENRY LLOYD, M.B., B.S. LOND.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain W. H. Lloyd, who was killed in action in France on August 4th, at the age of 27 years, was son of Walter Lloyd, J.P., of Carmarthen, and nephew of William Lloyd, F.R.C.S. Edin. He was educated at Queen Elizabeth Grammar School, Carmarthen, and took his medical course at Middlesex Hospital, obtaining the Conjoint qualification in July, 1915, and the M.B., B.S. Lond. later while on active service. After joining the R.A.M.C. he was attached for nine months to the 3rd London General Hospital, and in June, 1916, was sent to a casualty clearing station in France. More recently he was transferred to the London Regiment, with which he met his death while attending to wounded.

Captain Lloyd was an enthusiast both at work and play. One surgical chief writes of him as a delightful dresser, always helpful and inspiring. Another who gave him a considerable amount of experience in practical surgery states that he had never met with a more apt pupil. "He was able, skilful, and excellent in his work. But beyond all that he had a special personal charm that endeared him to all who knew him."

ALEXANDER BOYD FOOTT, L. & L.M. R.C.P. & S.I.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain A. B. Foott, who died in Egypt on July 21st, was 26 years of age, and son of the late Dr. St. John Foott, of Cork. He was educated at Monmouth Grammar School and Queen's College, Cork, qualifying in 1914, when he became resident surgeon at the Cork Eye, Ear, and Throat Hospital. He resigned this post in August of the same year to take a commission in the R.A.M.C., going to France in the following November. He was wounded at Loos in October, 1915. He went to India in June, 1916, was invalided home with sandfly fever, and went to France again in November, where he fell a victim to trench fever. In June of the present year he was sent to Egypt, where he died of malaria.

Captain THOMAS WHITMORE, C.A.M.C., who died of wounds on August 8th, aged 29 years, was a native of Dauphin, Manitoba. He graduated in medicine at the Manitoba University in May, 1915, and shortly after joined the C.A.M.C., and left for England in August. He served as Regimental M.O. until June, 1917, when he was posted to Granville Special Hospital, where he remained for a year before going to France to join the 3rd Canadian Field Ambulance, and later the 5th Canadian Battalion, with which he was serving when he received his fatal wounds.

Captain MALCOLM ARCHIBALD MCKECHNIE, C.A.M.C., who died as the result of wounds received on August 8th, aged 29 years, was a native of Gillies Hill, Ontario. He

graduated in medicine at Queen's University, Kingston, in 1914, left Canada for service overseas in November, 1916, and went to France in March, 1917. He was posted to the 6th Canadian Field Ambulance, serving for short periods with various units.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Lieut. J. B. P. Wells, Bedfordshire Regiment, died from wounds as a prisoner of war, son of Dr. A. P. Wells, of Victoria, British Columbia.

Lieut. P. Young, Middlesex Regiment, attached Machine Gun Corps, died of wounds, seventh son of the late Dr. E. Young, of Hawkhurst, Kent.

Lieut. K. S. Courtenay, Dorset Regiment, killed in action, only son of Dr. K. J. Courtenay, of Wareham, Dorset.

Capt. V. J. Whitaker, Lincs Regiment, attached R.F.C., previously reported missing, now officially presumed killed in action, April, 1917, second son of Mr. J. Smith Whitaker, of the National Health Insurance Committee, Buckingham Gate, London, S.W.

Lieut. R. L. Cummings, Australian Flying Corps, accidentally killed, second son of Dr. H. L. Cummings, of Tasmania, Australia.

Second Lieut. E. W. B. Maggs, King's Royal Rifle Corps, killed in action, only son of Mr. W. A. Maggs, of Upper Wimpole-street, London, W.

Major J. H. M. Hardyman, acting Lieut.-Col., Somerset Light Infantry, M.C., killed in action, eldest son of Dr. G. Hardyman, of Bath.

Second Lieut. E. N. Andrews, The Buffs, died of wounds, youngest son of Dr. E. C. Andrews, of Hampstead, London.

Lieut. J. M. H. Gerrard, R.F.A., died of wounds, eldest son of Major-General J. J. Gerrard, C.B., A.M.S.

THE HONOURS LIST.

The decorations conferred upon the following officers are for services rendered in connexion with the military operations in German South-West Africa:—

South African Medical Corps.

C.M.G.—Col. H. J. M. Buist, D.S.O., attached, from R.A.M.C.; Lt.-Col. R. P. McKenzie, R. of O.

O.B.E.—Maj. H. E. Brown; Capt. (temp. Maj.) T. F. Cope.

South African Medical Service.

D.S.O.—Lt.-Col. S. Meyer de Kock; Maj. L. G. Haydon; Lt.-Col. G. H. Knapp; Capt. G. B. Moffatt.

Military Cross.—Capt. J. E. Briscoe, D.S.O. (R. of O.); Capt. G. J. Cillie; Capt. (now acting Maj.) T. J. W. A. Johnston; Capt. J. J. Lynch; Capt. A. E. Oakley; Capt. (temp. Maj.) J. Pratt-Johnson; Capt. (temp. Maj.) R. N. Pringle, D.S.O.; Capt. F. K. Te Water; Capt. (temp. Maj.) J. A. Thwaits; Capt. (temp. Maj.) R. H. Welsh.

The following promotions and decorations are for services rendered in connexion with the military operations in Mesopotamia:—

C.B.—Col. W. H. Starr, C.M.G., ret. pay, A.M.S.

C.M.G.—Lieut.-Col. (temp. Col.) G. G. Delap, D.S.O., R.A.M.C.; Temp. Maj. (temp. Lieut.-Col.) R. Davies-Colley, R.A.M.C.

I.E.—Lieut.-Col. F. W. Gee, I.M.S.; Lieut.-Col. H. G. Melville, I.M.S.; Maj. (temp. Lieut.-Col.) G. Macpherson, I.M.S.; Maj. N. E. H. Scott, I.M.S.; Maj. W. R. J. Scroggie, I.M.S.

To be Brevet Major.—Capt. F. C. Cowtan, R.A.M.C.; Capt. A. MacD. Dick, I.M.S.; Capt. T. J. C. Evans, M.C., I.M.S.; Capt. A. H. Gosse, R.A.M.C.; Capt. S. W. Kyle, R.A.M.C.

D.S.O.—Maj. W. V. Coppinger, I.M.S.; Capt. and Bt. Maj. T. J. Mitchell, R.A.M.C.; Maj. (temp. Lt.-Col.) A. H. Proctor, I.M.S.

Military Cross.—4th Class Asst. Surg. A. N. de Monte, Ind. Sub. Med. Dept.; Temp. Lieut. E. A. M. J. Goldie, I.M.S.; Temp. Capt. J. A. Noble, R.A.M.C.; Temp. Capt. K. N. Purkis, R.A.M.C.; Lieut. (temp. Capt.) R. R. Thompson, R.A.M.C.

The following are the statements of service for which the decorations recorded in THE LANCET of April 6th, 1918, p. 516, were conferred. All are members of the R.A.M.C. unless otherwise stated:—

Military Cross.

Capt. ALAN COLPITTS AINSLEY.—For conspicuous gallantry and devotion to duty. Whilst attending to a man seriously wounded a shell burst within a few yards of his position and knocked him down. Despite this he continued with his work, and showed the greatest coolness and devotion to duty throughout the day.

Temp. Lieut. V. K. APTE, I.M.S.—For conspicuous gallantry and devotion to duty. He attended to the wounded during an action with great courage and coolness.

Lieut. CLAUDE WELLS WOOLLOTON BAXTER, I.M.S.—For conspicuous gallantry and devotion to duty. When under heavy shell and rifle fire he displayed great gallantry and devotion to duty in attending to and evacuating the wounded. His services proved of inestimable value.

Temp. Capt. WILLIAM KENNETH BIGGER.—For conspicuous gallantry and devotion to duty. He personally assisted in getting his wounded away from the dressing station under heavy machine-gun and rifle fire. Previous to this he had gone out from the dressing station on several occasions to tend the wounded at a time when no stretcher-bearers were available. He showed great gallantry and devotion to duty.

Capt. WILLIAM EDWARD HUGH BULL.—For conspicuous gallantry and devotion to duty. When in charge of a bearer section and collecting post he worked under shell and rifle fire, and with a few stretcher-bearers collected and tended a number of wounded cases under conditions demanding the utmost coolness, gallantry, and determination, qualities which he displayed in the highest degree.

Temp. Capt. NICHOLAS MARSHALL CUMMINS.—For conspicuous gallantry and devotion to duty. He gave valuable assistance to a unit after a successful attack in the organisation of stretcher-bearers, and he also organised several parties at night, which he conducted into "No Man's Land," for the purpose of recovering wounded cases. He worked on until every case had been evacuated, when he collapsed from exhaustion. His courage and devotion to duty were of the highest order.

Capt. CHARLES AUBREY GODSON, I.M.S.—For conspicuous gallantry and devotion to duty during an attack. All day he organised stretcher parties and collected the wounded, often under shell fire, and at night searched the whole area covered by the attack and cleared it of all the wounded. It was largely due to his courage and initiative that the evacuation of the wounded was carried out so successfully.

Capt. WILLIAM GOLDIE.—For conspicuous gallantry and devotion to duty when in charge of a collecting station, in advance of the advanced dressing station, during an attack. The rapid and successful evacuation of the wounded was due to his untiring zeal and energy. He showed magnificent courage and coolness under heavy fire, and set a splendid example to those under him.

Temp. Capt. BENJAMIN KNOWLES.—For conspicuous gallantry and devotion to duty. He was wounded at the beginning of an enemy attack, but returned to his aid-post and remained there, attending to the wounded throughout with great determination and coolness.

Capt. PERCIVAL JOHN MOIR.—For conspicuous gallantry and devotion to duty. While he was leading a party of 30 men and 8 camels to a forward position in order to establish an advanced dressing station the party came under heavy shell fire. He at once got his party under cover, unloaded the camels, and then got his medical stores forward under continuous shell fire. His promptness and courage not only prevented casualties, but enabled the advanced dressing station to be established at the earliest possible moment.

Capt. CHARLES NEWTON-DAVIS, I.M.S. — For conspicuous gallantry and devotion to duty. During the attack, and when the battalion was brought to a standstill by frontal and enfilade fire of all kinds, he exposed himself continually in moving from place to place to render aid to wounded cases. It was owing to his courage, devotion to duty, and skilful organisation that the wounded were successfully collected and evacuated.

Temp. Capt. REX STANSFIELD.—For conspicuous gallantry and devotion to duty during an engagement. He carried his medical pannier forward through a heavy barrage and moved about under heavy shell fire over the captured ground, collecting and bringing in the wounded. He set a splendid example of courage and devotion to duty.

Capt. BRYAN MONTAGUE TUKE, Spec. Res.—For conspicuous gallantry and devotion to duty. He went forward himself with the attacking companies, and throughout the engagement kept moving from one part of the line to another in full view of the enemy, attending to the wounded with the greatest promptitude and courage.

Capt. RANKINE GREIG WALKER.—For conspicuous gallantry and devotion to duty. He was in charge of an advanced dressing station during two engagements, and carried out his duties with great courage and skill, often under heavy shell fire.

BROUGHT TO NOTICE.

The names of the following medical officers, all members of the South African Medical Corps, have been brought to the notice of the Secretary of State for the Colonies for distinguished service in the field and in connexion with the campaign in German South-West Africa, 1914–15:—

Royal Army Medical Corps.—Capt. W. H. Biggs (T.F.); Capt. A. E. Bonham (T.F.); Temp. Capt. D. F. Borrie; Temp. Capt. J. T. Bowman, D.S.O.; Capt. K. P. Brown (S.R.); Temp. Capt. J. A. G. Burton; Temp. Capt. W. M. Cameron (S.R.); Temp. Capt. W. Campbell; Lt.-Col. (Temp. Col.) E. W. W. Cochrane, D.S.O.; Capt. V. Z. Cope (T.F.); Capt. F. C. Cowtan; Maj. and Bt. Lt.-Col. (acting Lt.-Col.) H. J. Crossley; Temp. Capt. L. W. Davies; Temp. Lt.-Col. R. Davies-Colley; Lt.-Col. (temp. Col.) G. G. Delap, D.S.O.; Capt. W. Dunlop (S.R.); Temp. Capt. A. R. Elliott; Temp. Capt. C. L. Emmerson; Lt.-Col. and Bt. Col. M. H. G. Fell, C.M.G.; Temp. Capt. G. J. C. Ferrier (Lt., Canadian A.M.C.); Maj. (temp. Lt.-Col.) F. E. Fremantle (T.F.); Capt. H. L. Garson (S.R.); Temp. Capt. A. T. Gibb; Temp. Lt. (temp. Capt.) G. T. Gimlette; Temp. Capt. E. N. Glover; Capt. A. H. Gosse (T.F.); Lt.-Col. (temp. Col.) S. F. StD. Green; Capt. T. P. Inglis (S.R.); Temp. Lt. E. Jamieson; Temp. Capt. E. Kidd; Capt. S. W. Kyle; Temp. Capt. C. G. MacKay; Temp. Capt. G. S. Marshall; Capt. A. N. Minns, D.S.O., M.C.; Capt. J. P. Mitchell (S.R.); Capt. and Bt. Maj. T. J. Mitchell; Temp. Capt. H. H. Raw; Capt. H. G. Robertson; Capt. E. A. Strachan; Maj. N. D. Walker; Temp. Capt. W. E. Waller; Capt. A. Watson, D.S.O.; Temp. Capt. C. A. Weller; Capt. (acting Maj.) H. M. Williams (S.R.); Capt. F. T. H. Wood (T.F.); Capt. W. B. Wood (S.R.).

Indian Medical Service.—Maj. (acting Lt.-Col.) R. M. Barron, D.S.O.; Capt. A. C. L. O'S. Bilderbeck; Maj. (acting Lt.-Col.) L. P. Brassey; Capt. H. H. Brown; Maj. S. R. Christophers, C.I.E.; Maj. (temp. Lt.-Col.) W. V. Coppinger; Maj. (acting Lt.-Col.) H. M. Cruddas, C.M.G.; Temp. Lt. A. Y. Dabholkar, M.C.; Capt. A. M. Dick; Capt. T. J. C. Evans, M.C.; Lt.-Col. F. W. Gee; Temp. Lt. S. C. S. Gupta; Capt. A. H. C. Hill; Capt. R. W. G. Hingston, M.C.; Maj. (acting Lt.-Col.) H. Innes; Lt.-Col. T. B. Kelly, D.S.O.; Maj. W. H. Leonard; Capt. A. P. G. Lorimer; Capt. R. F. D. Macgregor, M.C.; Maj. F. P. Mackie; Lt.-Col. R. H. Maddox; Lt.-Col. G. McPherson; Maj. W. A. Mearns; Lt.-Col. H. G. Melville; Capt. J. B. de W. Molony; Maj. D. Munro, C.I.E.; Temp. Lt. B. P. B. Naidu; Capt. J. J. H. Nelson, M.C.; Capt. M. A. Nicholson; Temp. Lt. C. E. R. Norman; Maj. (acting Lt.-Col.) A. H. Proctor; Capt. M. Purvis; Maj. W. R. J. Scroggie; Capt. J. L. Sen, M.C.; Capt. A. L. Sheppard; Lt. B. H. Singh; Capt. C. J. Stocker, M.C.; Capt. A. J. Symes; Maj. W. Tarr; Capt. W. O. Walker; Capt. W. L. Watson; Capt. F. P. Wernicke; Lt.-Col. (temp. Col.) C. N. C. Wimberley, C.M.G.; Maj. W. D. Wright; Maj. (acting Lt.-Col.) G. J. G. Young.

Indian Subordinate Medical Department.—1st Class Asst. Surg. G. A. S. Howatson; 2nd Class Asst. Surgs. H. A. Fox, G. H. Lawrance, H. B. Rosair; 3rd Class Asst. Surgs. A. F. G. D'Arcy, D.C.M., H. N. Murphy; 4th Class Asst. Surgs. F. M. Graham, V. M. Matthews, F. C. Vanderwart, J. F. de S. Vincent.

FOREIGN DECORATIONS.

French.

Legion of Honour.—Officer: Dep. Surg.-Gen. A. G. Wildey, R.N.; Col. C. K. Morgan, C.M.G., R.A.M.C. *Chevalier:* Fleet-Surgs. F. J. A. Dalton, C.M.G., R.N.; R. D. Jameson, R.N.; and A. J. Hewitt, R.N.

Croix de Guerre.—Capt. A. D. Edington, South African M.C.; Capt. G. J. Joubert, M.C., South African M.C.; Capt. W. W. McCowat, South African M.C.; Capt. F. Ward, R.A.M.C.; Temp. Capt. C. T. I. Clarke, R.A.M.C.; Temp. Maj. C. M. Row, R.A.M.C.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

N. A. Scott and R. D. Lockhart to be temporary Surgeons.

ARMY MEDICAL SERVICE.

Temp. Col. Sir Charles A. Ballance, K.C.M.G., C.B., M.V.O. (Captain, R.A.M.C., T.F.), relinquishes his temporary commission on re-posting, and is granted the honorary rank of Colonel.

The undermentioned Colonels retire on retired pay: E. Eckersley, F. W. G. Gordon-Hall, C.B.

ROYAL ARMY MEDICAL CORPS.

Major-Gen. W. H. B. Robinson has been appointed President of the Governing Body of the Bengal Medical Faculty, and Lieut.-Col. C. R. Stevens a member of the Governing Body.

Promotion of I.M.S. Officers.

The differentiation in regard to promotion to which officers of the Indian Medical Service have been subjected during the war has given rise to considerable comment. It is now announced that Captains of the Indian Medical Service will, if recommended, receive accelerated promotion to the same extent as has already been granted to Captains in the Royal Army Medical Corps on account of the war. The extent of such acceleration will be notified in the *Gazette of India* in due course. Acting rank will be granted to an officer of the Indian Medical Service officiating in an appointment in the field under the rules governing the grant of such rank in the Indian Army where applicable.

Two New Indian Surgeons-General.

Owing to the block in promotion which has been experienced for some time past it has been decided, with the approval of the Secretary of State for India, to create, for the period of the war, two additional appointments carrying the rank of Surgeon-General, such appointments to be filled by officers of the Indian Medical Service in military employment. These appointments, which will be created by converting two Indian Medical Service Colonelcies into Surgeon-Generalships, will carry pay at the rate of Rs. 2200 per mensem, and service therein will qualify for additional pension under Army Regulations, India, provided that the minimum service prescribed has been rendered.

DEATHS IN THE SERVICES.

Surg.-Gen. Charles Planck, I.M.S. (ret.), on August 23rd, aged 87. He served in the Indian Mutiny, and was at the relief of Cawnpore and Lucknow, being attached to the 90th Foot. At Cawnpore he was Field Surgeon. Subsequently he became Superintendent of the Agra Central Prison, Inspector-General of Prisons in Burma, and Sanitary Commissioner and Superintendent-General in the North-Western Provinces and Oudh. He retired in 1888.
Surg.-Gen. William George Birrell, of the Army Medical Service, has died at Lochboisdale, South Uist. He qualified M.B., C.M. Edin. in 1880 and entered the Army as surgeon on July 30th, 1881. He served in the Sudan Expedition of 1885, when he received the medal with clasp and the bronze star. He also took part in the Burmese Expedition of 1886-87, when he was mentioned in despatches. His last campaign was the Nile Expedition of 1898, when he was the recipient of the Egyptian medal. He was approaching his fifty-ninth birthday.

Correspondence.

"Audi alteram partem."

INFANT MORTALITY AND MOTHERCRAFT.

To the Editor of THE LANCET.

SIR,—Dr. W. A. Brend, in his letter published in THE LANCET of July 27th, refers to the increase in the industrial employment of women during the war, yet in spite of this there has been no rise in the rate of infant mortality.

Certain factors have tended to prevent any great increase in infant mortality during the past four years; the chief of these may be said to be the diminished birth-rate. In Derby, and generally throughout the country, the birth-rate during the year 1917 was the lowest recorded; the number of births registered in Derby in 1917 was 2332, while the number registered in the year 1913 was 3013, a difference of 681—that is to say, nearly one-fourth of the potential mothers might have engaged in industrial employment without prejudice to the rate of infant mortality. According to the Registrar-General (Sir Bernard Mallet) there were 881,890 births registered in England and Wales in the year 1913, whilst in 1917 the births registered fell to 668,346, a difference of 213,544, or a decline of 24 per cent.

Among other factors which have undoubtedly tended to reduction of infant mortality during the war, or at any rate have tended to prevent any increase in the infant mortality rate, have been (*a*) diminished alcoholism (Lord D'Abernon in a recent lecture delivered at the Royal Institute of Public Health stated: "The statistical and other evidence available indicates that insobriety among women both in public and in the home has, since the first year of the war, decreased to a level far below anything recorded in the past 50 years"); (*b*) climatic conditions during the war have not been favourable to the occurrence of summer diarrhœa—in fact, our last diarrhœa year was 1911; (*c*) other agencies which have helped to prevent increased infant mortality also, in my opinion, include the increased number of welfare centres, creches, &c., the formation of "Baby Week" Council, and generally the greater attention paid to infant welfare throughout the country since the war started; I might also include the maternity benefit obtained under the Insurance Act.

In spite of these factors favourable to infant welfare there has been some increase in the infant mortality rate in Derby. The mean rate during the three years 1912 to 1914 was 89 per 1000 births, that of the three years 1915 to 1917 was 94 per 1000 births, while in the whole of England and Wales the infant mortality rate during the year 1917 was 97 per 1000 births, as against 91 in 1916.

Dr. Ronald Carter, in his letter of the same issue, asks for figures showing the infant mortality among those attending welfare centres and among those not attending. I regret that I cannot give these figures, but certain statistics with regard to the feeding of children during the first three months of life who have been under the direct supervision of our health visitors in Derby are of interest as showing the paramount importance of breast feeding. Between the period Jan. 1st, 1908, and Dec. 31st, 1916, there were 26,532 births registered in Derby, and of these 24,676 were under the direct observation of the women inspectors; the death-rate per 1000 births of children breast-fed was 39·9, while that of the children hand-fed was 156·2, and that of children partly breast-fed and partly hand-fed was 149·8. The death-rate per 1000 births from diarrhœa was 4·0 among the breast-fed, while it was 37·5 among the hand-fed and 44·4 among those partly breast-fed and partly hand-fed.

I think these figures are, to use Dr. Carter's words, "distinctly disconcerting to the polluted atmosphere theorists."

I am, Sir, yours faithfully,

ALBERT E. BRINDLEY.

Public Health Department, Derby, August 20th, 1918.

THE TREATMENT OF WAR NEUROSES.

To the Editor of THE LANCET.

SIR,—Dr. T. Lumsden, in his letter to THE LANCET of August 17th, refers to our paper on war hysteria, and suggests that the methods of treatment we described should be followed by a "a three months' course of Country Host

convalescent treatment" in order to confirm the cure. In our opinion, however, a man who has been cured of hysterical symptoms in a Neurological Centre should remain there and work in the farm, garden, or workshops, until his cure is confirmed. In favourable cases he eventually returns to duty, and from all we have been able to hear the number of relapses is exceedingly small. The martial misfit, who ought never to have been accepted for the Army, is invalided, but he does not draw a full pension, as suggested by Dr. Lumsden, as he is never sent away until he is fit to earn a living in civil life, and we rarely recommend a pension of more than 20 to 40 per cent. Every man when he leaves us has already made arrangements for returning to work; he requires no further treatment, and we do not know of a single man invalided from our Neurological Centre who has relapsed.

The Country Host scheme is even less desirable for neurasthenia than for hysteria. It is absurd to suggest that any layman can take the place of the physician in the treatment of these difficult cases. In addition to direct psychotherapy, a combination of discipline, work, and amusement are required during convalescence, and this can only be obtained in a special hospital.—We are, Sir, yours faithfullly,

ARTHUR F. HURST.
J. L. M. SYMNS.

Seale Hayne Military Hospital, Newton Abbot,
August 19th, 1918.

THE PREVENTION OF VENEREAL INFECTION.

To the Editor of THE LANCET.

SIR,—I read with great interest and satisfaction the letter of "X. Y. Z." which appeared in THE LANCET of August 24th under the title of "40 D." I agree with those who oppose or deny much value to the "40 D" enactment, which has for its object the punishment of women who infect soldiers with venereal disease. The legal difficulty of proving the crime is well-nigh as hard as the medical one of curing the disease. Now, however, that really effective measures of preventing venereal *infection* have been at last established in the case of soldiers, and will, doubtless, become widely known and practised by civilians, the contention of "X. Y. Z." that instruction and facilities for similar prevention in the case of women should be equally disseminated is surely a sound one.

Doubtless the more medical prophylaxis is practised by men the fewer the number of infected women will be; but at this time, especially when the risk of infection is so great and its dire consequences are being spread so widely, it is both reasonable and urgent that the inroads of venereal diseases should be prevented *in both sexes* as effectively as possible and at the earliest available moment.

I am, Sir, yours faithfully,

London, August 28th, 1918. H. BRYAN DONKIN.

THE PSYCHOLOGICAL ASPECT OF 40 D.

To the Editor of THE LANCET.

SIR,—The protests of a certain section of the community against the examination of women suspected of transmitting venereal disease, to which you drew attention in a leading article in your issue of August 17th, may seem to many exaggerated and hysterical, but the psychologist, who studies the indirect effects of laws and who sees more and more the far-reaching influences of apparently unimportant matters, realises that the question is not one to be dismissed lightly or thoughtlessly.

One of the most important points to appreciate in discussing all laws, and especially the regulations we are considering, is that laws, whether they be permanent enactments or temporary regulations, are not impersonal matters, but actual living realities. The cruelest laws and the most heartless tyrannies have often been due to an impersonal method of criticism and to an inability to feel that legislation affects individuals and not abstract classes. In the present instance this evil is especially obvious. The problem is not whether we approve or disapprove of something called Regulation 40 D. It is whether we approve or disapprove of A. B., a young woman, age 23, who has been found to have become intimate with her lover C. D., being practically forced to undergo a physical examination by Dr. E. F., the prison doctor, or by Dr. G. H., whom she knows slightly or by some other doctor of whom she has never heard. Having put matters on the frankly personal basis from which all laws should be considered, we must further face the fact that A. B.'s examination is going to consist of a physical and mental experience possibly, and perhaps probably, very similar to that which she has had with C. D. Anyone who has studied carefully the growth of psychology during the past 10 years will know that I say this advisedly and without the slightest insinuation of improper conduct on the part of the doctor. A physical examination of the parts necessary to discover traces of venereal disease is not the same as a physical examination of any other parts of the body, and every psychologist knows that it arouses certain mental complexes which the physical acts necessary to make a proper examination tend to increase. But there is one very important difference between A.B.'s experience with C. D. and the examination, and it increases the evil effects of the latter. However transitory the relationship between A. B. and C. D. may have been there was some measure of sentiment, if not affection, whereas when similar mental complexes are aroused by a doctor in the course of his examination they are usually impersonal, and the mind, tending to centre on the feeling itself rather than on the person who arouses it, turns what should be a personal complex into a complex impersonal and self-sufficient. We are thus faced by the fact that the more strictly honourable the doctor is in his work the more impersonal will the girl's feeling usually become about matters that should be strictly personal, and what is supposed to be a safeguard becomes from another and a most important aspect a great danger. It must be fully realised, therefore, that Regulation 40 D does not merely place women at the mercy of the State, it places A. B. in the hands of Dr. E. F., who, if he has studied psychology, knows that with the best intentions and the most honourable adherence to the strictest rules of his profession he may do great harm, and do this harm by the very impersonality which his sense of honour dictates.

It must not be supposed that the effects of such an examination are always harmful; they may be negligible and sometimes even beneficial; but, whatever the type of woman we are examining, we are asking her to undergo an ordeal without the natural aid of affection or attraction which under other circumstances would tend to normalise her feelings. We must not forget that we are influencing emotional feelings at a time when they are at their highest and most susceptible, and that even if we do not arouse or increase a definite phobia or mania it is very probable that we are creating a changed attitude of mind towards certain most important questions. To say that the individual must be sacrificed to the good of society is in the present instance irrelevant, for we are spreading an atmosphere of publicity and promiscuity over matters which, in the interests of society as much as in the interests of the individual, should be kept on as intimate and personal a basis as possible.

Our outlook on legislation must be influenced by our growing knowledge of psychology. We must realise that in asking a girl to be examined for venereal disease the State is not merely testing her innocence, but is inevitably also testing her emotional character and her sense of modesty, and many complicated reasons may lead to her refusal. We must also understand that in making an examination of this kind the State does more than ascertain a physical fact about a girl's body, it also performs what to many may be a very serious psychological operation, and one that may lead indirectly to results which society unhesitatingly condemns and heavily penalises.

There must be many who have no special brief for the extension or for the repeal of Regulation 40 D, but who, if they realised the facts which have now become obvious to the psychologist, would demand a little deeper study of psychology by our legislators. If an examination is to become a permanent part of our legal methods of preventing the spread of venereal disease, the State should realise more fully the mental effect of its laws, and make some improvements which might mitigate their severity. The girl, for example, should be told frankly and fully what the examination means, and, whether she prefers the prison doctor or not, she should be always given the opportunity of having anybody present she chooses. There are, I am aware, doctors who insist on privacy in these matters, but there are also many with great experience who insist on the reverse, and

one, at least, of our greatest specialists refuses to perform privately an examination of this kind. It is obvious that when an examination is necessary as part of the legal machinery for the establishment of innocence the conditions of the examination should be made as easy as possible.

The law may often in its punishments produce results far different from those which it intends, but an increased study of psychology in connexion with punishment and with legal procedure will give us more insight into the effect of certain laws and suggest at least a few important alterations. By a little more sincerity and by a little deeper study we may realise that mental cruelty is often worse than physical, and, without unduly erring on the side of mercy or leniency, we may have a more exact knowledge of the effect of certain punishments on particular individuals and regulate them with a greater care and with a finer sense of the true meaning of justice. There are few matters that need a deeper knowledge of the indirect results of legislation than the questions we have been discussing. At a time not very far distant a scientific appreciation of the psychological effect of laws will be an accepted part of our social consciousness, and even to-day Governments are being forced before they legislate to accept scientific advice from many different quarters. Let us hope that the Government in considering such questions as those connected with Regulation 40 D will at least make an effort to face frankly questions of penal psychology which before long will be common knowledge.

I am, Sir, yours faithfully,

CYRIL BRUYN ANDREWS.

Reform Club, Pall Mall, S.W., August 21st, 1918.

THE FUTURE OF THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—In reference to Dr. Lauriston Shaw's letter in your issue of August 24th I should have thought that Professor Benjamin Moore and myself had made it perfectly clear that *the* form of competition which we would like to see abolished was competition for direct personal pecuniary gain, or, in other words, for patients and their fees. It is surely self-evident that this would be accomplished by the introduction of a whole-time salaried service, but Dr. Shaw confuses the issue by dragging in many other forms of competition which he rightly says such a service would not abolish.

In all walks of life there are forms of competition which it would be impossible, and indeed disastrous, to abolish, and it is so in medicine. There is nothing wrong with competition in itself, but the goal for which people compete may make it good or bad. It is good that men's varying powers should "be used to increase their opportunities of useful service"; it is bad that physical endurance and a plausible tongue should be used in competition to secure pecuniary reward at the expense of men with brains and conscience.

I am, Sir, yours faithfully,

August 26th, 1918. CHARLES A. PARKER.

COLONIES AND AFTER-CARE.

To the Editor of THE LANCET.

SIR,—In their article on Colony Treatment in THE LANCET of August 3rd Mr. P. C. Varrier-Jones and Professor G. Sims Woodhead completely misrepresent the work now done by tuberculosis dispensaries. They state:—

"Most of the consumptives now with us are 'advanced cases.' They flock to our new dispensaries, and the extensive statistics compiled from the records of the visits of these poor unfortunates are accepted as evidence of splendid things achieved."

Now, in point of fact, at no tuberculosis dispensary known to me do the advanced cases number more than 10 to 20 per cent. of all attending patients.

Even more curious is the statement that "Sir Robert Philip's well-thought-out scheme is being distorted and turned to very wrong uses." Now Mr. Varrier-Jones ought to know. He has been a close student of the writings of Sir Robert Philip, as anyone may discover who compares portions of unacknowledged text in Mr. Varrier-Jones's "Work as a Factor in the Treatment of the Consumptive Working Man" (Cambridge, 1915) with the same passages in addresses by Sir Robert Philip. For example:—

Sir R. W. Philip (THE LANCET, 1909, ii., 287) writes:—"It is time that we grasp the larger conception of tuberculosis as not merely the cause of overwhelming mortality and infinite distress, physical and economic, but also a great devitaliser of the race, indirectly responsible for an incalculable amount of other illness."

Mr. Varrier-Jones (1915, loc. cit., p. 6) writes: "It remains for us ... to grasp the larger conception of tuberculosis as not merely the cause of overwhelming misery and distress, physical and economic, but a great devitaliser of the race, indirectly responsible for an incalculable amount of other illness."

Nevertheless, I can see nowhere signs of distortion unless in the article under discussion. The tuberculosis dispensary is a central collecting and distributing station in a given area for the large mass of tuberculous patients. From the dispensary their homes are visited, and large numbers of infected people are thus discovered. The majority of early cases are successfully treated at the dispensary, and are enabled to continue their work by a change from unhygienic to physiological conditions, such as open windows, at home. From the dispensary patients are distributed to open-air schools, to sanatoriums, colonies, and to hospitals for advanced cases.

It is surely folly to send advanced cases, unable to work, to a colony, even if coffin-making were included among the trades of the colonists. Everyone with sanatorium experience knows the depressing influence of a death on the other patients, and colony patients will be likewise affected. Moreover, the general public will rightly object to infectious patients being deliberately set to any occupation concerned with the production of food or raiment. Lastly, there are obvious administrative difficulties in attempting to treat early, febrile, and advanced cases in the same institution. Sanatoriums filled with advanced cases have failed, and so, too, the work of colonies may be brought to nought.

Some enthusiasts cannot understand that the success of any institution for tuberculosis depends on its being coördinated into a harmonious scheme. A few years ago sanatoriums alone were to wipe out the disease, and now the same promise is being made for colonies. This tempts me to conclude with the prophecy that within five years open-air schools will be proclaimed as the one and only solution.

I am, Sir, yours faithfully,

August 21st, 1918. HALLIDAY SUTHERLAND.

URBAN VITAL STATISTICS.

(Week ended August 24th, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality was 10·8, against 10·4 per 1000 in each of the two preceding weeks. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 9·6, or 0·2 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 2·9 in Wimbledon, 4·7 in Eastbourne and in Rhondda, and 4·9 in Ilford, to 18·9 in Bootle, 20·7 in Wigan, and 22·6 in Rotherham. The principal epidemic diseases caused 420 deaths, which corresponded to an annual rate of 1·3 per 1000, and included 309 from infantile diarrhœa, 35 from diphtheria, 36 from whooping-cough, 29 from measles, 6 from scarlet fever, and 5 from enteric fever. The deaths from diarrhœa showed a further increase, and included 34 in London, 30 in Liverpool, 28 in Birmingham, 17 in Leeds, and 13 in Sheffield. The 710 cases of scarlet fever and 881 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 29 and 22 below the respective numbers remaining at the end of the previous week. Of the total deaths in the 96 towns 119 resulted from violence. The causes of 15 deaths were uncertified, of which 3 were registered in Birmingham and in Liverpool, and 2 each in London and Leicester.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 9·9, against rates steadily declining from 17·4 to 10·0 per 1000 in the five preceding weeks. The 236 deaths in Glasgow corresponded to an annual rate of 11·0 per 1000, and included 28 from infantile diarrhœa, 8 from whooping-cough, 4 from measles, and 1 each from enteric fever and diphtheria. The 53 deaths in Edinburgh were equal to a rate of 8·3 per 1000, and included a fatal case each of scarlet fever and infantile diarrhœa.

Irish Towns.—The 142 deaths in Dublin corresponded to an annual rate of 18·6, or 1·0 per 1000 above that recorded in the previous week, and included 23 from infantile diarrhœa, 4 from whooping-cough, and 1 from measles. The 108 deaths in Belfast were equal to a rate of 14·3 per 1000, and included 17 fatal cases of infantile diarrhœa.

POST-GRADUATE COLLEGE, WEST LONDON HOSPITAL.—During next week clinics will be held each week-day at 2 P.M., Wednesday, Friday, and Saturday also at 10 A.M.

THE Local Government Board has issued an appeal to local authorities to set an example of economy by reducing to the minimum consistent with safety the consumption of coal, gas, and electric current in all undertakings under their control. They are further asked to take every opportunity of impressing upon the public the paramount necessity of economy, as, for example, by care in the use of water which has to be pumped either at the waterworks or at the sewage disposal works, or both.

Appointments.

BOURNE, A. W., M.B., B.C., F.R.C.S., has been appointed Obstetrician in charge of Ante-natal Department, Queen Charlotte's Hospital.
MAY-ATKINSON, H. KING, M.B., Ch.B. Vict. Manch., Medical Officer of Child-Welfare Centre, Manchester Corporation.
PAUL, HUGH L., M.B., Assistant Medical Officer at the Leeds Sanitary Committee's Hospitals.
RICHARDS, W. J., Visiting Physician to Shieldhall Hospital.
SEMPLE, AGNES L., M.B., Ch.B. Aberd., Resident Medical Officer, Dundee Poorhouse.
WATT, J., M.A., M.D., D.P.H. Aberd., Medical Superintendent of the Downs Sanatorium, Sutton, Surrey.

Vacancies.

For further information refer to the advertisement columns.

Berkshire Royal Hospital, Reading.—H.S. £250.

Wolverhampton and Midland Counties Eye Infirmary.—H.S. £200.
Wolverhampton and Staffordshire General Hospital.—Asst. H.S.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Spilsby, Lincoln.

Births, Marriages, and Deaths.

BIRTHS.

CLARK-JONES.—On August 29th, at Burbage, Marlborough, Wilts, to Dr. and Mrs. Clark-Jones—a daughter.
COPLANS.—On August 26th, the wife of Captain C. Coplans, R.A.M.C., of a daughter.
HELM.—On August 30th, the wife of Captain (acting Lieutenant-Colonel) C. Helm, M.C., R.A.M.C., of a son.
HILL.—On Sept 2nd, at Rutland-square, Dublin, to Kathleen Josephine (*née* Kenny), wife of Captain J. F. Hill, M.C., R.A.M.C., B.E.F., France—a son.
JONES.—On August 26th, at The Manor House, Tamworth, the wife of R. Francis Jones, M.R.C.S. Eng., L.R.C.P. Lond., of a son.
MENNELL.—On August 29th, the wife of James B. Mennell, M.D. Camb., M.R.C.S., L.R.C.P. Lond., Royal-crescent, London, W., of a son.
PARROTT.—On August 30th, at Ross, the wife of Harold W. Parrott, M.B., B.Sc. Lond., of a daughter.
ROBERTSON.—On August 29th, at Westbourne-terrace, Glasgow, the wife of Captain Berkeley H. Robertson, R.A.M.C., of a daughter.

MARRIAGES.

GRAHAM—PAUL.—On August 31st, at St. John's Church, Kensington, Captain James Wells Graham, R.A.M.C., to Jessie Cameron, daughter of W. H. Paul, Park House, Stroud, Glos.
HOWELLS—MILES.—On August 28th, at Llanishen Church, John Francis Howells, Surgeon, R.N., to Dora Gwendoline, youngest daughter of Mr. James Miles, J.P., and Mrs. Miles, The Pines, Penylan, Cardiff.
MARSHALL-SEWELL.—On August 31st, at St. Alfege Church, Greenwich, Captain Reginald Prynne Marshall, R.A.M.C., M.R.C.S. Eng., L.R.C.P. Lond., to Emily Kate, second daughter of Mr. H. B. Sewell, solicitor and coroner, and Mrs. Sewell, of Croom's Hill, Greenwich, S.E.
PENMAN—WALTER.—On August 22nd, at the Parish Church, Bromley, Hugh Forrest Penman, M.B., Ch.B. Edin., Lieutenant, R.A.M.C., to Jessy Dorothy Walter, second daughter of the late William Walter and of Mrs. Walter, Willow Bank, London-road, Bromley.

DEATHS.

BRIDGES.—Accidentally drowned while on active service abroad Lieutenant-Colonel Roland Harley Bridges, D.S.O., R.A.M.C., aged 30.
KIDD.—On August 20th, at White Rock, Hastings, Joseph Kidd, M.D., aged 94.
MAXWELL.—On August 23rd, at Elmsligh-road, Paignton, suddenly, James Burns Maxwell, B.A. Cantab., M.R.C.S., L.R.C.P.
SAUNDBY.—On August 28th, at Hagley-road, Edgbaston, Birmingham, Robert Saundby, M.D., F.R.C.P., LL.D., Lieutenant-Colonel, R.A.M.C.(T.), Emeritus Professor, University of Birmingham.
TENNENT.—Killed in action on August 22nd, Major Bernard Charles Tennent, M.C., R.A.M.C.
WARD.—On August 30th, suddenly, at Wellesley House Hospital, Aldershot, William Alfred Ward, M.R.C.S., L.R.C.P. Lond., L.S.A., Major, R.A.M.C., aged 49.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

EDITORIAL NOTICE.

In consequence of the pressure on our space and the shortage of paper, the Editor may be compelled to abbreviate communications, as an alternative to their rejection, when time does not allow them to be reconsidered by their authors.

Communications, Letters, &c., to the Editor have been received from—

B.—Capt. P. H. Bahr, R.A.M.C.; Dr. G. Blacker, Lond.; Board of Agriculture and Fisheries, Lond.
C.—Dr. H. P. Cholmeley, Forest Row; Dr. Velasquez de Castro, Granada; Dr. F. G. Crookshank, Lond.; Coal Controller's Office, Lond.; Chicago School of Sanitary Instruction.
D.—Dr. R. Donaldson, Reading; Capt. F. C. Drew.

Medical News.

CHILD WELFARE.—A special course of lectures on infant care for health visitors, nurses, midwives, school teachers, and others will be held from Sept. 16th to 20th in the lecture theatre, University College, Nottingham. The lecturers include Sir Francis Champneys, Dr. Mildred Burgess, and Dr. Mary Scharlieb. The fee for the course is 10*s*., or 1*s*. 6*d*. for a single lecture, the text-book being "Mothercraft."—Another special course of lectures will be given at Swansea, in the Secondary School for Boys, on Saturdays, beginning on Oct. 5th and ending on Nov. 2nd. The fees and text-book will be the same as above.—At 1, Wimpole-street, London, W., from 5.30 to 6.30 P.M. on Mondays, from Sept. 30th to Dec. 16th, an elementary course of lectures on infant care will be given in preparation for the elementary certificate of the National Association for the Prevention of Infant Mortality, the lecturers being Dr. F. Truby King, Mr. H. G. Adamson, Dr. H. C. Cameron, Dr. Maurice Craig, Captain F. Vincent Denne, Dr. T. N. Kelynack, Dr. Eric Pritchard, and Miss Norah March. The fee for the course is 5*s*. Application forms and full particulars may be obtained from the Secretary, National Association for the Prevention of Infant Mortality, 4, Tavistock-square, W.C. 1.

ROYAL MEDICAL BENEVOLENT FUND.—The following is a continuation of a summary of cases relieved:—

Daughters, aged 56 and 53, of M.R.C.S. who practised at Kingscliffe and died in 1890. Each has an income of £11 6*s*. from dividends. They obtain occasional work as governesses, but at present without work. Each relieved three times. £9 each per annum. Voted £9 in 12 instalments.—Widow, aged 51, of M.R.C.S. Eng. who practised at Bampton, Oxon, and died in 19.6. Was left with limited means and one daughter, now aged 19, who is training for a teacher. Income from dividends, £10. Brother pays the rent and helps a little. Relieved twice, £20. Voted £10 in two instalments.—Widow, aged 55, of L.R.C.P. & S. Edin. who practised at Blackpool and died in 1912. Applicant left without means. Friends provide about £30, and she is now endeavouring to support herself by taking paying guests, but owing to ill-health can only do so on a very limited scale. Relieved twice, £10. Voted £5.—Daughter, aged 68, of M.R.C.S. Eng. who practised at Liverpool and died in 1881. Applicant lost her income by the failure of an Australian bank and is a permanent invalid dependent on friends and help from the Fund. Relieved five times, £60. Voted £12 in 12 instalments.—Widow, aged 73, of L.R.P.S. Glasg. who practised at Rochdale and died in 1899. Was left unprovided for at her husband's death and her children, all of whom are married, can only help a little, and applicant is too old to work. Relieved once, £12. Voted £12 in 12 instalments.—Daughter, aged 37, of M.D. Dub. who practised at Moorcroft and British Guiana and died in 1884. Applicant was left without means and suffers from tuberculous glands, so unable to work. Relieved 12 times, £110. Voted £10 in two instalments.—Widow, aged 76, of M.B. Edin. who practised at Ladswade and died in 1913. Her late husband died after a very long illness and all their savings were exhausted. Applicant is now dependent on help from friends and help from the Fund. Relieved once, £12. Voted £12 in 12 instalments.

Subscriptions may be sent to the acting honorary treasurer, Dr. Samuel West, at 11, Chandos-street, Cavendish-square, London, W. 1.

LONDON INTERCOLLEGIATE SCHOLARSHIPS BOARD.—The following Medical Scholarships have been awarded:—*University College:* Bucknill Scholarship: I. W. Gallant, Central Foundation Boys' School, and University of London, University College. Medical Exhibitions: H. Rosenberg, Central Foundation Boys' School, and University of London, King's College; B. Deane, Botham School, York; *proxime accessit*, Rachael Halperin, University of London, University College. *King's College:* Warneford Scholarships: P. B. Wilkinson, Plymouth College; M. G. L. Perkins, Westminster School, and University of London, King's College; L. H. Savin, Christ's Hospital, Horsham. *Westminster Hospital Medical School:* Natural Science Scholarship: M. Stieber, University of London, University College. *King's College Hospital Medical School:* Science Scholarship: Christine P. Francis, Brighton High School. Arts Exhibition: W. P. H. Sheldon, Bancroft's School. *London (Royal Free Hospital) School of Medicine for Women:* St. Dunstan's Medical Exhibitions: Margaret E. Reynolds, North London Collegiate School; Ellen M. Howard, St. Paul's Girls' School. Isabel Thorne Scholarship: Ethel A. Perrott, Bromley High School. Mabel Sharman-Crawford Scholarship: Dorothy N. L. Leverkus, London (R.F.H.) School of Medicine for Women.

THE CANCER DEATH-RATE IN LEICESTER.—In his annual report for 1917 Dr. Killick Millard, medical officer of health for Leicester, says the deaths from cancer and malignant disease numbered 255, equivalent to a rate of 1·17 per 100,000 of the population, the highest rate yet recorded in the borough.

THE death is announced of Mr. Damer Harrisson, Colonel, A.M.S. (T.), lecturer on clinical surgery in the University of Liverpool and honorary surgeon to the King.

Notes, Short Comments, and Answers to Correspondents.

HERB-GROWING AND BOTANIC DRUGS.

THE Royal Horticultural Society in a recent circular urges on educational authorities and commercial corporations the importance of developing the vegetable wealth of the Empire. The dislocation in the vegetable drug traffic due to the war has already had an effect in stimulating the study of medical botany and the production of books dealing with various aspects of the subject. Dr. Thomas Blair, in his preface to *Botanic Drugs* (Cincinnati, Ohio: The Therapeutic Digest Publishing Company. Pp. 394), remarks that there are 19 countries with well-based pharmacopœias recognising 550 botanic drugs. Dr. Blair anticipates a growing market for these medicinal products, and he presents the reader with a careful record.—The author of *Histology of Medicinal Plants*, Dr. W. Mansfield (London: Chapman and Hall; New York: John Wiley and Sons. Pp. 305. Price 13*s*. 6*d*. net), is professor of histology and pharmacognosy in the College of Pharmacy attached to Columbia University, N.Y., where he has had many years' practical experience in examining powdered drugs for commercial purposes. An account is given of the various plant tissues and the cells composing them, the book going on to deal with the histology of roots, stems, barks, flowers fruits, and seeds. Many excellent original illustrations embellish the text.—A fourth edition has also just appeared of Professor L. E. Sayre's large *Manual of Organic Materia Medica and Pharmacognosy* (Philadelphia: P. Blakiston's Son and Co. Pp. 606. Price $4.50), which contains, along with a very full introduction to the study of the vegetable kingdom, details of preparation of all vegetable drugs and practical chapters on such matters as the insects injurious to drugs. More than 300 illustrations are given.—Attention may be called to the exhibit at the British Scientific Products Exhibition (now being held at King's College, London) of home-grown vegetable drugs by the School of British Medicinal and Commercial Herb-Growing. Mrs. H. Grieve, principal of the school, is president and advisory expert to the British Guild of Herb-Growers, which represents a movement to recapture permanently from Germany and Austria the herb-growing industry. In a leaflet which may be obtained from Mrs. Grieve (The Whins, Chalfont St. Peter, Bucks) a full list is given of the medicinal plants which may be grown in this country.

MEDICAL MEN AND THE VOLUNTEER OBLIGATION.

A RECENT Circular (R. 224) sent down by the Local Government Board and the Scottish Office to local and appeal tribunals deals with the duties and obligations of the Volunteer Force. Every person exempted by a tribunal is liable to be called on for Volunteer service unless the tribunal orders otherwise, and this liability rests equally on the medical man. The line, however, taken by the Medical Tribunal is that doctors should not be called on as a rule to join as Volunteers, as their services are too urgently required for medical work, and the exemption certificates so far issued have invariably contained an order stating that the applicant should not be liable to join the Volunteer Force. This will protect all who apply to the Medical Tribunal, and until their cases have been considered by the tribunal they cannot be called on to perform duty as Volunteers.

THE CARE OF THE FOOT.

ALTHOUGH it is abundantly true that an army marches on its belly, the foot requires some consideration. Major T. Rugh, in charge of military orthopædics at the office of the Surgeon-General, U.S. Army, tells us (*American Journal of Orthopedic Surgery*, August, 1918) that the Munson shoe has solved all the difficulties of corns, callosities, ingrown nails, overriding toes, and blisters of the feet. Intelligent care is now being applied to soldiers' feet on this side of the Atlantic. Under the title of "First Aid for Foot Troubles" (London: Scientific Press, Ltd., 1*s*. 3*d*. net.) Mr. E. G. V. Runting, President of the Incorporated Society of Chiropodists, has written a little book designed to render the soldier more efficient, and also, as Dr. A. W. Oxford points out in a foreword, with the aim of popularising throughout the country the work carried on at the headquarters in London. After emphasising the need for patience and attention to detail if battalion chiropody is to be carried out effectively, the author gives detailed instruction in the care of the nails and the treatment of their malformations, describing the various pads—corrective and protective—that have been found of service in chronic cases among soldiers. The importance is great of keeping the feet of marching men as healthy as possible, and the book should prove useful to this end.

CONDITIONS OF SERVICE AND OF PAY FOR SPECIAL RESERVE, R.A.M.C.

FROM inquiries received from time to time it is evident that the conditions of service and of pay in the auxiliary R.A.M.C. branches are not as well known as they might be, and the following summary of conditions prevailing under the Special Reserve may be useful for reference:—

First appointments will be made to the rank of Lieutenant, on probation. (*Para. 71, Regulations for Special Reserve, 1911 (latest).*)

A candidate for the R.A.M.C. must be under 30 years of age, and either (*a*) registered under the Medical Acts, or (*b*) a member of the Officers Training Corps who has completed that portion of the curriculum of a student of medicine which at the time of his appointment places him in a position to obtain diplomas or degrees entitling him to be registered as a medical practitioner in two years from the date of his appointment. (*Para. 81.*)

Application for commissions in the Special Reserve of Officers will be made on Army Form B 201, which will be forwarded to "The Secretary, War Office, London, S.W.," through the officer commanding his contingent, if the candidate is a member of the O.T.C., or through the officer commanding his unit, if a member of the Territorial Force. (*Para. 82.*)

If the candidate holds a commission in the Territorial Force, the officer commanding the unit to which he belongs will certify (on Army Form B 201) as to his fitness for the Special Reserve. It will not be necessary for him to resign his commission in the Territorial Force: his commission [in Territorial Force] will be determined [i.e., will cease to exist] as from the day preceding date of appointment as probationer to the Special Reserve. (*Para. 83.*)

On appointment to a commission the candidate will receive instructions as to his probationary training, usually through a General Officer Commanding-in-Chief. (*Para. 85.*)

On completion of his probationary training, and passing prescribed examination, and being satisfactorily reported on, he will be confirmed in his commission, with effect from date of first appointment on probation. (*Para. 86.*)

Liabilities and Conditions of Service.—An officer of Special Reserve of Officers will be liable to undergo training for the period and at the place which may be prescribed for his branch of service (six months recruit training), but not outside the United Kingdom without his own consent. (*Para. 93.*)

Liability to be called up for army service at home or abroad, at a time of imminent national danger of great emergency, when the Army Reserve is called out, until his services are no longer required. (*Para. 95.*)

Such liability extends from date of joining Special Reserve of Officers until expiration of a year from date of completion of his probationary period; and so on from year to year, until he attains 40 years of age. (*Para. 96.*)

Promotion.—Eligible for promotion to Captain after 3½ years, and to Major after 12 years' service.

Commission in Regular Forces.—An officer R.A.M.C. Special Reserve may, if otherwise eligible, compete for a commission in the R.A.M.C. (*Para. 113.*) An officer of Special Reserve, when called out for service in national emergency, will be eligible for commission in Regular Forces, if not over 30 (if a subaltern), or 40 (if of higher rank).

Pay, Additional Pay, Extra-duty Pay, and *Allowances* of officers of *Special Reserve* called up during an emergency will be in all respects similar to those of a regular officer of same rank and arm of service. (Quarters 3*s.* daily, fuel and light 1*s.* 1*d.* + 6*d.*, servant.) (*Para. 413.*) Special grant of £50 as compensation for disturbance and for kit, if called up during an emergency. (*Para. 419.*) Outfit allowance of £20 (one-fourth to be refunded for each year or portion of a year that he fails to complete of the period of four years, except in cases of sickness). (*Para. 426.*)

THE CARNEGIE ENDOWMENT FOR INTERNATIONAL PEACE.

THE director of the Division of International Law, Mr. James Brown Scott, has done well to bring out at this time two volumes having an important bearing on international relations. The first of these is a collection of papers relating to the Controversy over Neutral Rights between the United States and France, 1797–1800 (pp. 510, price 15*s.*), and deals with the difficult question of armed neutrality; the second volume recapitulates the Declaration of Independence, the Articles of Confederation, and the Constitution of the United States (pp. 100, price 4*s.* 6*d.*), documents which the editor justly claims to be fundamental to the world's development. In so far as these books contribute to the intelligent pacification of the peoples of the earth, they will have helped to produce an atmosphere in which the peaceful art of medicine can flourish once more. Both books are published by the Oxford University Press in New York.

SPECIFIC PARAPLEGIA IN CATTLE AND HORSES.

Mr. William Scott, F.R.C.V.S., of Bridgwater, has been experimenting with a vaccine in connexion with a specific paraplegia which has recently been affecting cattle rather frequently. The disease is local in its occurrence and soured pasture and the poor nutritive value of hay and roots appear to have made the bovines peculiarly susceptible to a form of paralysis which leaves them unable to rise for weeks at a time. The investigator has obtained a vaccine from cultures made from an organism found in the spinal fluid of animals affected. The fluid was extracted by means of a lumbar puncture between the fourth and fifth or fifth and sixth vertebræ. In 31 cases the injection of the vaccine produced very good results. The treatment is new and the great prevalence of the disease has not been noticed before, although isolated cases have been recorded from time to time. Mr. Scott deserves commendation for his enterprise in conducting a line of investigation and treatment which has not hitherto been tried. The only other disease in animals in which inoculations are prepared from spinal material appears to be rabies. Direct interference with the spinal column has been rarely undertaken to produce therapeutical results, but intraspinal anæsthesia has been brought about in dogs by puncture in the sixth interlumbar space and injecting cocaine, stovaine, or novocaine. In Mr. Scott's cases a louse (*Hæmatopinus tenuirostis*) was found almost constantly affecting the ailing subjects, and this louse harboured a bacillus identical with that found in the host's blood. Four similar cases of paraplegia were met with in equines.

A USEFUL FIELD INCINERATOR.

Major C. S. Williamson, M.R.C., United States Army, describes in the *Military Surgeon* for July a form of incinerator suitable for a large base camp where there is some scarcity of fuel, which he calls a "multiple-shelf incinerator." It is built of brick lined with fire-brick, 12 ft. high, and internal measurement is 4½ × 6 ft. It has six shelves 3½ × 6 ft., placed alternately right and left, and there is a fire-grate below. The fire is started with 200 lb. of wood, the garbage is dumped on the top plate to a depth of 4 in. or so, and after it has dried a little it is pushed over on to the second plate, and another charge introduced. The second plate, after a little more drying, gives up its charge to the third, and so on. Ultimately there will be a layer on the sixth plate, dry, and an inch thick, which will take fire itself, and should be then, but not till then, pushed on to the fire-grate, when it will burn and dry the succeeding charges. The incinerator will burn 10–15 tons of garbage in 24 hours, and will deal with fæces if mixed with the garbage in equal quantities. Clearly the available garbage should be so managed that the incinerator is never empty, but kept, by judicious feeding, always burning. The device deserves attention.

COLONIAL HEALTH REPORTS.

Gilbert and Ellice Islands.—Mr. E. C. Eliot, the Resident Commissioner, in a report to the Colonial Office, writes: The following table gives the births and deaths for 1916–17 as contrasted with the past three years:—

	Gilbert Islands.				Ellice Islands.		
	1913–14.	1914–15.	1915–16.	1916–17.	1913–14.	1915–16.	1916–17.
Births ...	891	773	817	701	161	142	136
Deaths ...	734	967	626	628	155	100	94

At Ocean Island there has been an increase in the death-rate, mainly owing to the serious drought. Since the close of the year 1916–17 a considerable number of Banabans (Ocean Islanders) have died, in spite of the efforts made by the Government in the importation of fresh vegetables, lime-juice, &c. Steps have been taken to prevent the northern spread of elephantiasis from the Samoan Group. Ordinance No. 6 of 1917 provides for medical inspection for microfilaria of all persons wishing to travel from Samoa to this colony. A considerable amount of research work in connexion with pulmonary tuberculosis and in the use of salvarsan or equivalent preparations in filariasis has been undertaken by the medical department, which has received commendation and encouragement from members in England of the Advisory Medical and Sanitary Committee for Tropical Africa. A substitute for salvarsan is now being obtained from Japan. The necessity for constant supply of this valuable preparation is still urgent, both in cases of syphilis and yaws.

W. H. K.—The suggestion that cœliac disease may be due to the use of the dummy or pacifier is open to the objection that this disease frequently begins at an age when they are not in use. Moreover, the pacifier is very common, whereas cœliac disease is rare.

M. D. O'C.—Although it was not until the fifth day of the fever that many tertian parasites were found in the peripheral blood stream, their presence was obviously possible in the blood of the organs. The old view that Laveran's bodies are pseudo-parasites would imply that altered red corpuscles can conjugate in the stomach of the mosquito, and produce oocysts, sporoblasts, and sporozoites. Doubtless cases of malarial fever have been recorded in which Laveran's bodies could not be discovered in the blood, but how is a diagnosis of malaria at all to be made without finding parasites? The toxin of the malaria parasite has not been isolated, but neither has that of the spirochæte of syphilis.

Dr. F. G. Crookshank writes to disclaim any connexion with an unregistered practitioner of somewhat similar name who has recently made application for certain hospital appointments in London.

A Lecture

ON

THE PREVENTION AND ARREST OF LICE-BORNE DISEASES BY NEW METHODS OF DISINFECTION.

Delivered before the Royal Society of Medicine on July 17th, 1918.

BY COLONEL WILLIAM HUNTER, C.B., A.M.S.,

PRESIDENT OF THE ADVISORY COMMITTEE FOR PREVENTION OF EPIDEMIC DISEASES IN EASTERN WAR AREAS, 1915–1917; COLONEL IN CHARGE OF BRITISH MILITARY SANITARY MISSION TO SERBIA, 1915; CONSULTING PHYSICIAN TO THE EASTERN COMMAND.

INTRODUCTORY.

THE subject of this lecture relates to the prevention of lice-borne diseases—typhus, relapsing fever, and trench fever. I am not concerned with the evidence as to the lice-borne character of these diseases, nor with the life habits of lice, nor with the degrees of heat required to kill them, but I have been greatly concerned with killing them in masses by an overwhelming amount of steam in the presence of which all life is impossible. My interest has been not in costly and complicated appliances for disinfecting—usually not available when and where they are required and insufficient to meet the needs when they are—but in simple methods, available at all times and absolutely efficacious in killing body vermin, easily improvised, easily worked, extremely effective, the very "Columbus egg of simplicity and efficiency," as they were described by one enthusiastic Serbian official. This interest, born of a great necessity, in dealing with the appalling conditions I had to face in Serbia in 1915, has given the subject of disinfection a new importance in my eyes, and it has been my experience to extend that interest to conditions prevailing in Eastern war areas.

These results have been from time to time officially recorded in reports submitted from the Serbian and Eastern Mediterranean war areas, where my duties for two and a half years have lain—first as O.C. of the British Military Sanitary Mission of 25 R.A.M.C. officers sent out to Serbia in February, 1915; and subsequently from July, 1915, to June, 1917, as President of the Advisory Committee for Prevention of Epidemic Diseases in all the Eastern war areas. These duties throughout have related to preventive work against all infectious diseases, among which lice-borne diseases have been among the most prominent and difficult to deal with.

The origination of two new types of disinfectors, called the "barrel disinfector" and the "railway van disinfector" respectively, was the first work of the British Military Sanitary Mission sent out, at the request of the Serbian Government, at two days' notice and under the most urgent circumstances, by the War Office on Feb. 15th, 1915, under my charge, to deal with the great epidemics of typhus and relapsing fever and typhoid fever then raging in that country.

On our arrival we found that the whole country was ravaged by these infections without any available measures for disinfection or equipment, even in the largest hospitals, to meet the urgent conditions. The barrel disinfector was devised by my colleague, Lieutenant-Colonel G. F. Stammers, R.A.M.C., on March 7th, three days after our arrival in Nish, and was set up and put into use the following week in Kragujevatz, the headquarters of the Serbian Army.

The railway van disinfector was devised by the same officer about ten days later to meet the needs of disinfection of troops on a larger scale, and to form a part of the *British Sanitary Train for Inoculation and Disinfection*, which we had decided to form for the work of the mission.

DISINFECTION ON THE LARGEST SCALE BY RAILWAY VAN DISINFECTORS.

The principle of primary importance in connexion with disinfection against lice-borne diseases is the necessity of carrying out disinfection on the *largest possible scale* and in the *shortest period of time*—the object in view being in any individual unit to kill off within a period of a few days every living thing in the clothes and on the body that may have possibly contracted infection and be capable of conveying such infection.

This principle is carried out—with a rapidity and efficiency unapproached by any other method of disinfection—by the current steam railway van disinfector. Simple and eminently practical, this type of disinfector, originally devised as above stated, was first put into use in Serbia. It was subsequently introduced under my direct personal supervision in Egypt in February, 1916, with modifications which added seven- to ten-fold to its working capacity and rapidity of action. The results were closely watched all the time till I left Egypt in June, 1917.[1]

The van disinfector both in principle and efficiency is totally different from other various contrivances—e.g., steam pressure boilers *on* trucks ("truck-disinfectors")—which have been put into use on railways for purposes of disinfection. The principle of its action is disinfection *by current steam*, supplied by and directly discharged in greatest volume and force into one or two ordinary railway vans (suitably adapted) by the railway engine, which conveys them along the line to the place most conveniently adjacent to the troops. (Figs. 1–3.) The cost of adaptation is only £30 to £40, the working of it simple and easy.

There is, of course, nothing new in the principle of using current steam as a disinfecting agent. What is new, and what I claim to the credit of the English Sanitary Mission in Serbia, is the application of this principle for purposes of widespread disinfection by new methods and on a larger scale than had ever before been devised.

Rapidity of Disinfecting Action.

The working capacity of the railway van disinfector here described is very large, and the arrangements simple to carry out, as shown in Figs. 4 and 5.

Each double van is capable, from my personal knowledge and observation, *if fully employed*, of carrying out disinfections at the rate of 500 kits with 1000 blankets and 500 overcoats every 2 hours; of 2000 kits with 4000 blankets and 2000 overcoats in a day of 8 hours; of disinfecting over 10,000 kits with 20,000 blankets and 10,000 overcoats in 4 days; and 18,000 kits with 36,000 blankets and 18,000 overcoats in 9 days.

With one disinfector alone I have disinfected the kits and blankets of a hospital with 1000 beds in 4 hours; the kits, blankets, and camp bedding of 4000 prisoners of war in 16 hours; of 1500 camel corps men in about 12 hours.

Divisions of troops can be dealt with at the following rate: 8000 men in 4 days, 15,000 in 12 days (3800 of these being done in one day); of 16,000 in 12 days; 10,000 in 4 days; and 18,000 in 10 days.

As regards *ordnance clothing*, this can be disinfected, in sackfuls at a time, at the rate of many thousands of articles every 2 hours, tens of thousands daily, and hundreds of thousands weekly.

A most striking illustration of the advantages of this rapidity was afforded in one instance, where a van disinfector which had just disinfected a division of 18,000 troops in 12 days in one area went off about 500 miles to a centre in Southern Europe, where some cases of typhus had occurred among the native labourers. It disinfected the whole of the troops and labourers (1500 in number) in three days, and was back at work again in its former area disinfecting another division on the fourth day.

In the first three months of their work the two van disinfectors carried out the disinfection of 170,000 kits, 170,000 overcoats, 340,000 blankets, and great masses of ordnance clothing. Since that time the disinfectorr in use have been the most prominent and effective measure of preventive work in Egypt, each double van disinfector being capable of carrying out in the simplest and most efficient way in all parts of the war area—up to railhead—disinfection of troops and native labourers to the number of 60,000 men monthly. The total number of disinfections carried out in 12 months (May, 1916, to April, 1917) among a monthly average of 40,000 labourers was 495,000—an average of over 40,000 a month.

This rapidity of work does not apply to all railway van disinfectors as such, but only to the original Stammers's van disinfector as modified by me in Egypt (Cairo Van 5511). The feature of this latter form is that the volume and force of steam are so great, and its method of dispersion

[1] The circumstances there did not permit any definite information to be furnished regarding its working capacity before the Mission left Serbia early in June, 1915.

from the pipes so arranged that it is possible (for the first time in the history of disinfection) to disinfect bundles of clothing in bulk without unpacking or spreading them out. The advantage of this in connexion with disinfection against lice-borne diseases is obvious, since it permits clothes to be disinfected without any handling of individual articles.

Comparison of Working Capacity of Double Van Disinfectors with Other Types of Disinfectors in Army Use.

The working capacity in two hours' time of the double van disinfector as compared with that of all the chief types of disinfectors in use in the Army is indicated graphically in Chart 1 for (*a*) blankets, (*b*) kits (exclusive of overcoats) respectively. The figures for the other types of disinfectors are those officially given in "Notes for Sanitary Officers, B.E.F., France, 1917" (W.O., 1918), p. 42.

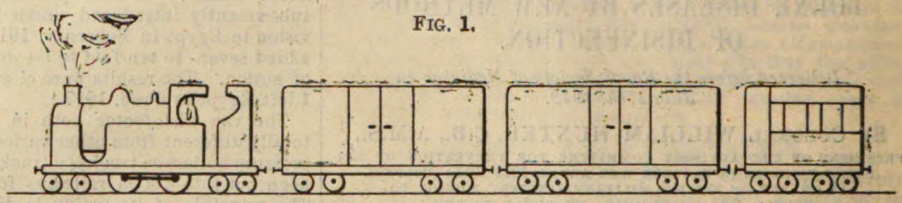
* Average of 40,000 labourers. † Sleeping mats. ‡ Large masses.

The double van disinfector can deal with 500 men at a time. It was found to work with absolute uniformity, the exposure given being an hour for van full up with kits, and 15 minutes for the overcoats, which were thrown in loosely. Many of the kits were extremely lousy when collected, and examination showed that in every case all the lice and their eggs were dead and shrivelled up after disinfection in the van.

The results of the first eleven days' and first three months' work of the two disinfectors, the records of which were carefully kept, are shown in Table II., while the scale on which kits, overcoats, and blankets were dealt with from day to day during the first three months by two van disinfectors is graphically shown in Chart 2.

FIG. 1.



The current steam railway van disinfector as introduced into Egypt in 1916.

RELAPSING FEVER AMONG NATIVES IN EGYPT.

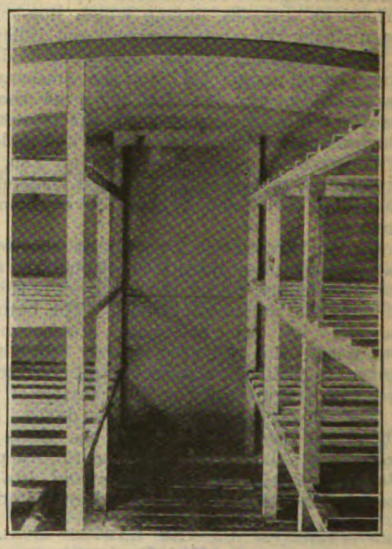
The course of events may here be briefly summarised in a narrative form.

Being satisfied from my previous experience in Serbia in 1915 that the available means of disinfection were altogether inadequate to meet even a moderate incidence of relapsing fever, I suggested that the circumstances of an outbreak of relapsing fever among the native labourers in Egypt could best be met there also by the use of the railway van disinfector.

I submitted my proposals, and got permission to form the type of van disinfector I suggested. It was formed in the railway works at Cairo from a steel van and old engine which I selected and found available. The work was most expeditiously and thoroughly carried out. The adaptations, which were made in four days, included, in addition to other modifications, the use of a small railway engine for the combined purposes of locomotion and production of steam, instead of a small heating engine employed in Serbia, and proved on the first trial by me two days later to add enormously to the rapidity of action and efficiency of the van as a disinfector.

They enabled me to dispense with all the delay inseparable from unpacking, spreading out, and repacking of the clothes disinfected. This adaptation made it possible for the steam to penetrate in great volume and force into the centre of even the largest bundles of clothes. This was proved by numerous tests — eggs being boiled hard, potatoes cooked, cultures sterilised, flies enclosed in test-tubes killed, and, most conclusive of all, a self-registering thermometer — even when enclosed in its case — closed in at both ends and put into the centre of the largest bundle, registering temperatures of 102° to 105° C. (215° to 220° F.) as early as half an hour after the steam was turned on from the engine into the van.

FIG. 3.



Interior view of the same van.

I spent the first fortnight in testing its working in all classes of work in which it could be required, and in each and every direction the results obtained exceeded expectations.

FIG. 4.

The double van steam railway disinfector in use in Egypt. Two queues, each of 250 men, are seen approaching to deposit their infected kits in the vans. The disinfection was completed in one hour, the overcoats in 15 minutes, the men were bathed, and the whole process was completed in two hours. 2000 men were dealt with on this day in the course of eight hours.

Four other similar disinfectors with double vans were subsequently formed.

Efficacy of Van Disinfectors in Prevention of Relapsing Fever.

A study of the results obtained in Egypt showed the closest relationship to exist between the incidence of the disease and the amount of disinfection carried out in the unit affected.

If the disinfection can be carried out rapidly in the whole of the unit the disease is thoroughly arrested.

Place A.—In this place the outbreak was the first to occur and the sharpest. This was the first place I disinfected with the van disinfector (Feb. 25–27th, 1916). I made it a test disinfection. The kits and blankets of 485 labourers (viz., 485 kits, 485 blankets, and 333 overcoats) were thoroughly disinfected. The men all bathed during the disinfection; the heads of some 50 men were shaved; and then finally to complete the disinfection I had every single article of clothing or bedding found in their tents collected in large sacks, brought to the disinfector, and thoroughly disinfected. The time taken for the whole process was 5 hours.

At the same time I disinfected completely (in 6 hours) 347 kits, 195 overcoats, and 694 blankets of the unit in which the relapsing fever cases had occurred; 80 kits and 1057 blankets of the field ambulance and the stationary hospital concerned in dealing with these cases (in 3 hours); and finally 62 large sacks (two full van loads) of ordnance clothing (in 4 hours).

The result of the first seven days' work served to establish conclusively its exceptional merits and efficiency. I asked that another one should be formed, with two vans attached instead of one. This was immediately done, and completed as before in a week's time; I found it ready in the railway works in Cairo on my return on Saturday, March 18th.

It was arranged that it should be sent the following morning to a siding adjacent to a large hospital, where I carried out the disinfection of 850 large hospital kits in two fillings of the vans in the course of 4 hours; and of 500 camel drivers in the afternoon; of 1800 camel drivers the following day; and of 3500 Turkish prisoners on two following days.

The sequel to the disinfection—of an exceptionally complete character carried out at Place A—was complete arrest of infection. Only three cases occurred in the next 12 months instead of over 50 in the month when the disinfection was carried out.

Place B.—The course of events in this place was also most interesting. This was the seat of the largest labourer camps, the number up to December, 1916, averaging 3000–4000 men. The monthly incidence of the disease in the first months of 1916 was very high, amounting in April and May to 6·68 and 6·15 per cent. of the number of labourers. Up to May no disinfections were carried out, but from May onwards a steadily increasing disinfection was commenced and continued throughout the year.

From July onwards the whole of the labourers were being disinfected at least once, and from August onwards two or three, and sometimes four, times a month.

The disease was practically stamped out; the incidence during the following winter was only 16 cases instead of 530 cases in three months of the preceding year, rising only once to 0·39 per cent., at a time when elsewhere it was as high as 8·35 per cent.

If the whole of the unit cannot be disinfected within at most 2–3 weeks (i.e., the incubation period of lice-borne diseases), then the disease continues to occur, although lessened in incidence, men becoming reinfected with infected lice from those who have not been disinfected.

This is the prime reason why hitherto lice-borne diseases have continued to propagate themselves for a certain, and sometimes (e.g., trench fever) indefinite, period, apparently in

FIG. 5.

Part of the same queue as in Fig. 4 showing the bundles of infected clothing which are placed unopened in the van. The large size of the bundles is shown.

CHART 1.

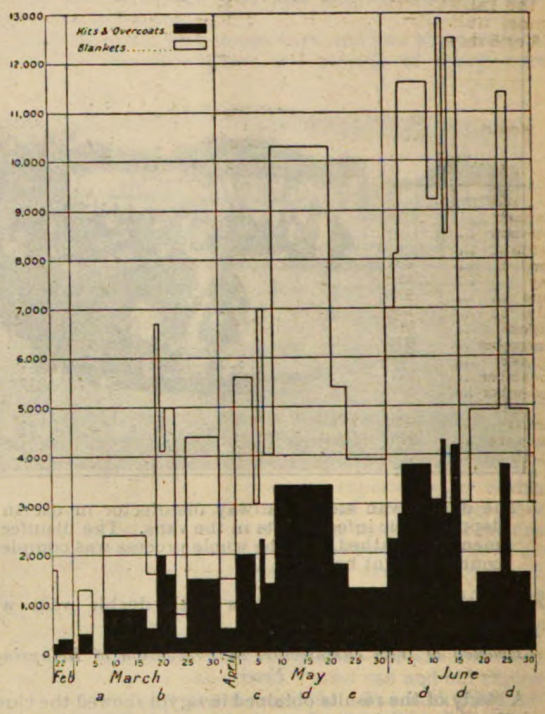
CHART 2.



A graphic record of the achievement from week to week of a double van disinfector.

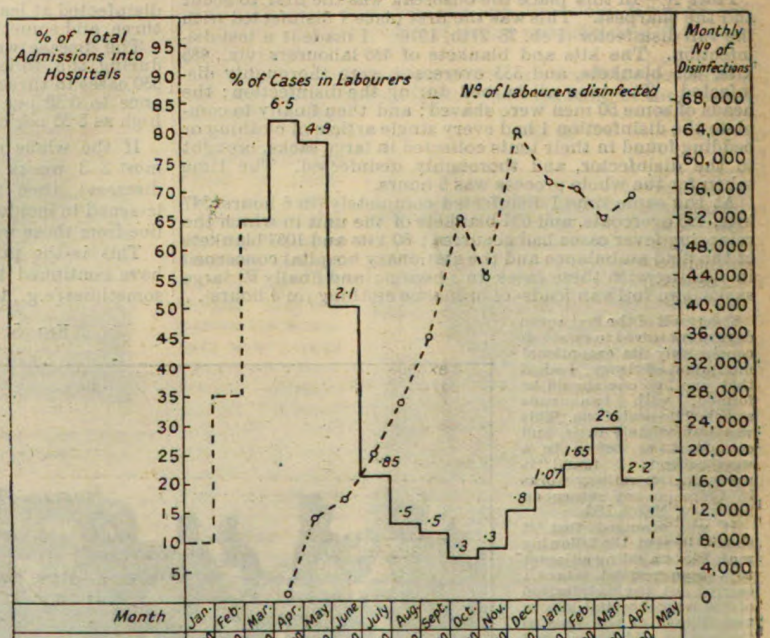
spite of what may be an amount of disinfection absolutely large, but quite insufficient to cover the whole of the affected unit within the incubation period of the infection.

The above conclusion is well illustrated by a study of the incidence of relapsing fever in labourers' camps in Egypt, of which the following is a sample.

Place C.—One of the largest and most important labourers' camps was at Place C, an important railway junction of the Egyptian railways. The incidence in this group early in 1916, before disinfection was commenced, was high—viz., 10 per cent. in April and 4 per cent. in May. When disinfections were commenced in June they did not cover in any month all the labourers in camp up till December. The result was that although the incidence fell it was never entirely arrested, and it rose again as high as 4·5 per cent. the following winter.

It is to be noted that, although inadequate when commenced in arresting the incidence, the actual amount of disinfection in the following five months (June to November) was considerable. In terms of what has hitherto been considered possible, it might even be deemed satisfactory—viz., 3000 to 8000 men monthly—averaging 4000 in a body of men averaging about 6000. It represents a daily average of about 130 men—approximately the steady work of two portable Threshes. Nevertheless, it did not suffice to check the disease for the reason which I emphasise—viz., that disinfection to be effective in arresting a louse-borne disease in any area should be capable of being applied to the whole of the individuals in that area within a maximum period of 2–3 weeks; and if the infection be severe within a shorter period of one week, and repeated, if necessary, a week or ten days later.

CHART 3.



Month	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Jan.	Feb.	Mar.	Apr.	May

Incidence of relapsing fever among labourers and its control by disinfection.

In the case of groups numbering as many as 6000 to 8000 men this requirement may seem a counsel of perfection—desirable, perhaps, but not practically obtainable under military conditions. This is no longer the case; for, by use of the railway van, disinfection can be carried out on an almost unlimited scale. Such numbers can be dealt with in 4 or 5 days.

The incidence of relapsing fevers in other groups of labourers in the area illustrates the same points.

Summary of Results in Egypt.

The sequel showed the following results:—

(*a*) The incidence was very effectively controlled by the amount of disinfection which it proved possible to carry out by means of van disinfectors among the natives, and its threatened incidence among the troops was immediately checked and controlled. (Chart 3.)

(*b*) The incidence among the *natives*, which when at its height, affected 6·5 per cent. of the labourers in any one month, never exceeded 2·6 per cent. in any one month in the following winter.

(*c*) Instead of constituting, when at its height, as much as 82 per cent. of the total admissions into hospital in any one month, it did not in any month exceed 30 per cent. (Chart 3.)

(*d*) Instead of affecting in any one month as many as 15 per cent. of the labourers in any one locality, it remained in nearly all places on a very low level—below 1 per cent. In only two places did it exceed 5 per cent., and even in these cases the incidence was at once checked by the extra and immediate disinfection which it was possible to bring to bear by means of the van disinfector.

(*e*) Its spread to the *troops* was effectively prevented or controlled.

The total number of cases among them in the four months (March to June) following the introduction of the van disinfectors in February, 1916, was only 143—all cases then ceasing.

Although this incidence was a small and satisfactory one, having regard to the large number of troops and the presence amongst them of so many cases of relapsing fever among the native labourers, the number appeared to me to be relatively large, in view of the exceptionally large amount of disinfection that had been carried out among the troops during this period.

I therefore made a close analysis of the cases, ascertaining in each case the place and date of their reporting sick, whether in the Northern Section van, where van disinfectors had been chiefly at work (over 150,000 disinfections), or in the Southern Section where the van disinfectors had been little in use (only 7000 disinfections).

The interesting result that appeared was that out of the total 143 cases that had occurred—March to June—only 30 had occurred in the Northern Section among its large

	Natives.		Troops.	
	% of total number.	% of total cases.	% of total troops.	% of total cases.
Northern Section ...	60·0	50·0	80·0	20·0
Southern Section ...	40·0	46·0	20·0	80·0

number of troops (80 per cent. of the total troops), whereas no fewer than 113 cases had occurred in the Southern Section among its small number of troops (less than 20 per cent. of the total troops.)

There was thus a marked difference between the spread of the disease to the troops in the Northern and Southern Sections respectively.

(*f*) In the Southern Section reliance had been placed on the large disinfecting station at Place F to carry out the disinfection necessary in its neighbourhood. Nevertheless, the number of cases among the troops at this place was the largest in any place, totalling 91 cases out of the total of 113 cases in this Southern Section.

The official data regarding the amount of disinfection carried out by this large disinfecting station, equipped with four of the largest steam-pressure boilers, show that the total number of troops disinfected was about 32,000 in the six months, a number which one double van disinfector (Cairo Van 5511) is capable of disinfecting, as shown on more than one occasion, in 14–21 days—e.g., 10,000 in 4 days, 18,000 in 9 days, 3800 in 1 day—a total of 31,800 in 14 days.

While stationary disinfectors can only be used for those in their neighbourhood, the van disinfector can carry out this large number of disinfections daily over an area of 100 miles or more whenever and wherever they are required.

LICE-BORNE INFECTION AMONG TROOPS IN THE FIELD.

It is clear from the foregoing that to deal effectively with such conditions the disinfection must be capable of being brought to the troops, so as to be accessible to them wherever they are; it must be capable of dealing with them rapidly and in great numbers at a time, in order to interfere as little as possible with military duties; and be easily improvised on the spot and capable of being easily and expeditiously worked without need of special knowledge or technique or special personnel.

All these requirements are in my experience met—in a manner unapproached by any other type of disinfector—by the van disinfector (Cairo). Looking back at the circumstances in the Egyptian war area and on the results which I followed for a year and a half, I feel satisfied that in the absence of this form of disinfector the problem of relapsing fever in the war area would have occasioned military difficulty and materially impeded the prosecution of the campaign. Before the introduction of the van disinfectors among the natives nearly one-fifth of the average number of labourers were attacked by relapsing fever, but by disinfection on the largest scale by this disinfector the disease was effectively arrested or stamped out or controlled.

(*To be concluded.*)

THE RÔLE OF THE SCAPULA IN THORACOPLASTY.

BY JOSEPH E. ADAMS, M.S. LOND., F.R.C.S. ENG.,
CAPTAIN, R.A.M.C. (T.); SURGEON WITH CHARGE OF OUT-PATIENTS TO ST. THOMAS'S HOSPITAL, ETC.

SOME ten years ago I performed an extensive thoracoplasty on a man, aged 21, who had a left-sided empyema containing no less than 10 pints of pus, drained for several weeks without any evidence of expansion of the lung or any sign of the displaced heart returning to its proper place. He was exhibited before the Royal Society of Medicine in January, 1910,[1] 18 months after operation, in a very good state of health, with very little deformity beyond flattening of the chest on the affected side, and physical signs pointing to the existence of a healthy lung on this side of rather more than half the normal size.

I was congratulated on the very satisfactory result, which those present appeared to attribute to the fact that the plastic operation was performed six weeks after the original drainage of the pleural cavity and the consequent expansion of the lung before the visceral pleura became very thick. Personally, I do not think this good result would have been obtained if the chest wall had been "allowed to fall in," as is usually said in text-books to be the object of a thoracoplasty, and I attributed it to the use of the scapular muscles to obliterate part of the cavity, to pull up the diaphragm, and to pull on the lung by movements of the arm, when the scapula was made to occupy the place of the excised ribs. Recent experience has confirmed my opinion, and it seems to me that hardly any case of old-standing empyema is likely to resist surgical intervention provided a proper use of the scapula and the muscles attached to it is made and every

[1] Transactions of the Royal Society of Medicine, Clinical Section, January, 1910.

effort is directed towards closure of the chest at the operation. The whole secret of success in recent war surgery of the chest has been shown to depend on the closure of the chest wall, and, if the expansibility of the lung remains, there is every prospect of complete cure even from severe lesions. I have recently operated along the same lines in the case of an empyema where another surgeon had operated twice and left a wide gaping wound after 15 months' treatment which showed no sign of closing. The first operation performed was decortication of the lung, and the second aimed at the division of adhesions between the parietal and thickened visceral pleura. Such operations are doomed to failure unless steps are taken to close the thoracic cavity, and this cannot be done by merely dissecting up skin flaps and bringing them across the mouth of the cavity; the lung will not expand if it lies exposed at the bottom of an open wound against atmospheric pressure, and my operative procedure aims at the closure of the cavity with muscle and the favouring of expansion of the lung both by active movements and conditions of intra-thoracic pressure.

Notes of Case: Description of Operation.

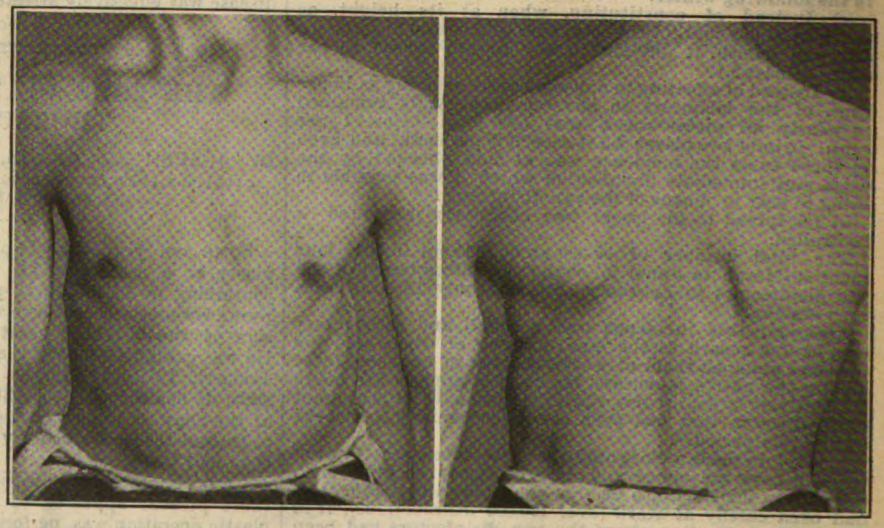
The notes of my case operated upon in 1908 are as follows:—

Patient, aged 21, a pale and thin man with marked respiratory distress, lying on his left side and perspiring freely. There was evidence of a total empyema on the left side; some tubular breath sounds were audible over the upper half of the lung, but they were absent over the lower half, and neither vocal fremitus nor resonance was conducted at all. There were no adventitious sounds. His respirations were 40 to the minute and the pulse-rate 120. The heart was displaced so far to the right that pulsation could be felt in the right axilla. Very shortly after admission the left side of the chest was aspirated, and seven pints of greenish-yellow, sweet-smelling pus were drawn off. Some few hours later two inches of the left seventh rib were resected just behind the mid-axillary line. Not less than three pints of pus escaped, some thickened fibrin was removed from the pleural cavity, and a drainage-tube just entering the pleura was fixed in the wound. From this pus the pneumococcus was grown in pure culture. The drainage of the empyema was satisfactory, taking into account the large size of the abscess cavity, and at the end of three weeks there was very little discharge. Four weeks after operation the heart was still displaced beyond the right border of the sternum, and there was very little evidence of function in the left lung. X ray examination revealed abnormal transparency of the left chest, with a thin strip of shadow, to the left of the median vertebral opacity, in which the collapsed lung lay.

At the request of the physician, Dr. T. D. Acland, I undertook a second operation to secure closure of the cavity and expansion of the lung. The patient was anæsthetised with chloroform and rolled over on to his right side. The left arm was pulled a short distance across the chest and a long incision, parallel to, and 1 inch behind, the vertebral border of the scapula, terminating in the original mid-axillary wound, was made down to the level of the ribs and intercostal muscles. This incision split the trapezius and the latissimus dorsi and the lower part of the rhomboideus major, leaving a large portion of them attached to the scapula. Portions of the sixth, seventh, eighth, and ninth ribs were then resected subperiosteally; 6 inches of the seventh and eighth being removed, 2½ inches of the ninth, and a smaller portion of the sixth rib. The intercostal muscles, periosteum of the ribs, and thickened parietal pleura were next cut away with scissors, and such vessels as bled were easily secured by underpinning with catgut sutures. There was very little loss of blood and the shock of this part of the operation, which is commonly supposed to be one of its dangers, was very slight. The resulting wound was an open trough, comprising the whole pleural cavity, with the shrunken lung at the bottom, lying close against the thoracic spine. The lung though shrunken was still expanding a little with inspiration and the visceral pleura was not greatly thickened.

The next step in the operation consisted in suturing the muscular flap attached to the scapula to the lower portion of the lung and the diaphragm, the visceral pleura being just thick enough to hold catgut stitches when lightly tied; the scapula was then pushed into the cavity so that it occupied approximately the place of the resected ribs, and the stumps of the trapezius and latissimus dorsi were freed from the overlying skin and sutured to the surface of the muscle attached to the vertebral border of the scapula. The object of this procedure was immediately to lessen the size of the pleural cavity and to secure for the lung a space, half the size of the original pleural cavity, which it might be able to fill when its expansion was aided by the movements of the left arm and the pull of the muscles passing from scapula to lung. The cavity was gently sponged out with saline, but it did not appear sufficiently clean to close without drainage; therefore, a large rubber tube was left in the wound, its upper end reaching to the bottom of the new pleural cavity and its lower end emerging through the skin incision at its lowest anterior limit. The rest of the skin incision was closed with interrupted salmon-gut stitches. If I had done this operation to-day I might have risked the infection and closed the wound completely (leaving a new-formed pleural cavity part of whose bony wall would be formed by the scapula, divided into the upper pneumothorax and a lower space occupied by muscle). There was a good deal of discharge for a few days and the patient complained of slight pain on respiration. His left arm, which was not anchored by the bandage, he declined to move to any extent as this caused considerable pain. In a few days the patient's condition was markedly improved and breath sounds were audible over the front of the left chest. A fortnight after the operation breath sounds could be well heard all over the front of the chest down to the level of the skin incision and at the back to within 1 inch of it; the heart had returned very nearly to its correct position, and a radiogram revealed a pulmonary shadow extending midway between the left sternal border and the outer chest wall; expansion of the lung could be seen on the fluorescent screen, but there was less than the normal amount of brightening of the lung on inspiration. The patient soon began to look fat and well

FIG. 1.



Condition 18 months after operation.

and the amount of discharge steadily diminished. After five weeks in bed he was allowed to get up and he walked about the ward without any respiratory distress. The wound finally healed ten weeks from the time of operation and has never given any trouble since.

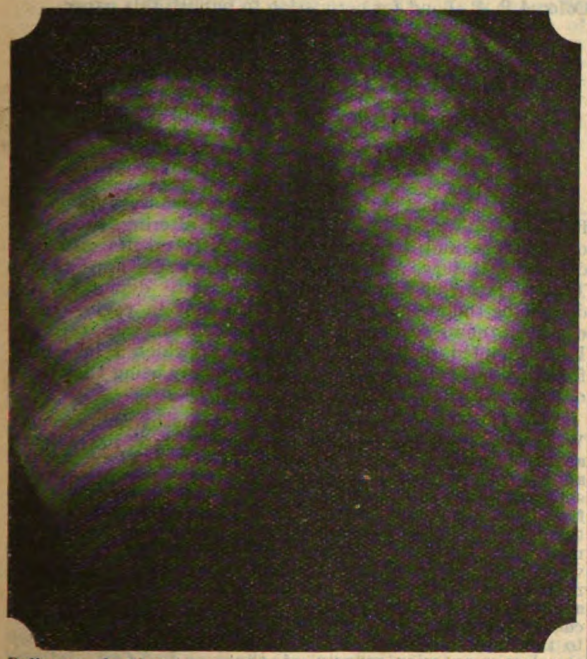
Subsequent Condition.

The condition 18 months after operation was as follows, the absence of any marked deformity of the chest being well shown in Fig. 1. There is some flattening of the left side of the chest and slight deviation of the dorsal spine with convexity of sixth to twelfth dorsal vertebræ to the left, presumably due to the pull of the scapula. The movements of the arm are perfectly free. The left chest is resonant from the apex to the site of the scar; breath sounds are normal in front as far down as the scar, and posteriorly down to 1 inch below this level; irregular breath

sounds can be heard as low as the eighth rib in front and a little way below the scar at the back. Vocal resonance and fremitus are both present. There is fair visible expansion of the upper part of the left chest on inspiration. No adventitious sounds. Skiagraphy shows equal movement of the diaphragm on both sides, but the left cupola is a little higher than the right. The right lung is seen from apex to upper border of the eleventh rib, the left lung from apex to upper border of ninth rib.

Examination on April 25th, 1918, revealed the same physical signs except that the right side of the chest was more developed, and therefore the relative sizes of the two sides of the chest showed to the disadvantage of the side which had been operated on. Auscultation and percussion gave the same results as in 1909, and the heart was in its

FIG. 2.



Radiogram showing the area of functional lung, the elevation of the left cupola of the diaphragm, and the slight deviation of the spine with convexity to the left. Taken ten years after the operation.

normal position. The patient was up to his normal weight, and the only inconvenience was dyspnœa on exertion, and for this reason he had very properly been rejected by the recruiting board. X ray examination showed a bright lung equivalent to rather more than half that present on the right side. The left cupola of the diaphragm was the higher, and it rose obliquely towards the outer chest wall.

Fig. 2 is a radiogram of the chest taken ten years after operation, which shows a large proportion of active lung on the affected side and practically no deformity of the chest.

The recent case which I have operated upon on similar lines unfortunately died suddenly of endocarditis, but the post-mortem examination afforded an opportunity of ascertaining that this operative procedure had secured firm adhesions between the scapular muscles and the lower part of the lung and diaphragm; the lung itself was considerably more expanded than it had been at the time of operation.

A careful review of the literature of thoracoplasty reveals the fact that the scapula is usually regarded as an obstruction, and a partial resection of it is recommended by some authorities. In my view, however, the bone of the scapular body may be utilised to take the place of resected ribs, and its muscles may be of value in securing mobilisation of the lung and raising of the diaphragm, both essential factors in healing of these cases.

Devonshire-place, W.

HOSPITAL SUNDAY FUND AT BRISTOL.—£4166 have been raised in Bristol as the result of the Hospital Sunday collections; this amount exceeds all former records by more than £1000.

Mr. J. Wickett, of Redruth, Cornwall, has given 1000 guineas to the funds of the West Cornwall Miners' and Women's Hospital.

GUNSHOT WOUNDS OF THE KNEE-JOINT WITH SEPTIC ARTHRITIS.

BY ARTHUR NEVE, F.R.C.S. EDIN.,
MAJOR, R.A.M.C.; SURGICAL DIVISIONAL OFFICER, WAR HOSPITAL, DARTFORD.

NO further evidence is now required that most knee-joints which have been perforated by bullets or severely wounded by shell fragments, with injuries of the bones, may be saved by timely measures. Much credit is due to the overseas surgeons who have worked out the various methods and the careful technique by which this is achieved.

Our concern in this country is not with such cases, which only need rest and massage to complete the cure, but with the critical and threatening cases arriving in convoys, it may be from 7 to 14 days after being wounded, in which signs of infective arthritis are already well marked.. It is such cases which tax the judgment of the surgeon as to the compatibility of conservation of the limb with safety to life.

The articles[1] by Sir George Makins, Colonel Barling, and other surgeons now with the B.E.F. in France show that the importance of the subject has been recognised, and also that the infective cases with septic arthritis, especially when associated with bony damage, stand in a separate category of infinitely greater impending danger than the others. The figures point to the gravity of the infected cases, which are not totalled separately. On a total of 845 cases of knee-joints of all kinds operated upon, of which a large majority may well have been free from septic arthritis, the amputations were 19 per cent. and the deaths 8·5 per cent. Max Page on a total of 70 cases gives 25 as infected, amputations 10, deaths 5 = 20 per cent. mortality. Rankin gives 29 cases of excision with 8 deaths, but of these 3 were due to other complications; 3 others were finally amputated. These and other figures emphasise the seriousness of the condition when once sepsis develops.

The more recent convoys from France received at Dartford have shown many encouraging results from early operation in France, with excision of the wound, removal of foreign bodies, thorough cleansing of the joint, and primary suture. At the time of writing there are 10 healed cases in this hospital, not one suppurating and not one amputated for arthritis. A year ago similar injuries would have arrived here in a highly septic condition. We never amputate septic knees speedily after admission. If the man was passed by the surgeons abroad as fit for the journey and not requiring immediate amputation we may so far endorse their opinion as to carry on conservative treatment until he has got over any special exacerbation due to the transit.

Drainage.

Of late much has been written about the difficulties of drainage of the knee-joint, with all its bursæ and pouches. Some of us had been working at these problems long before the war.

The kernel of the question is how to obtain adequate *posterior* drainage, for the back of the joint is swathed in ligamentous and muscular structures, with interstitial bursæ and tendon sheaths, and in close contact with the posterior ligament is the popliteal artery. Obviously, any drainage-tube behind the crucial ligament would risk hæmorrhage. But postero-lateral incisions on both sides should be made to the synovial pouches behind the condyles by the method of Labey adopted by Campbell and Gill.[2] This is much simpler than Payr's method.

Anterior drainage is comparatively easy. The simplest way is to make an incision 1 inch long into the suprapatellar pouch on the side nearest to the surgeon, push curved forceps through to the other side, cut down on the points, and with them grasp a medium-sized drainage-tube, which is thus drawn through. Then the same procedure on either side of the ligamentum patellæ. This usually needs to be combined with posterior drainage. The excellent suggestion has been made that a patient should be placed and kept face downwards, with dependent drainage through an anterior wound and tubes, but this is only a temporary expedient.

[2] Brit. Med. Jour., 1917, i., 798.

Transverse incision.—To obviate the need for multiple incisions, especially the posterior ones, some surgeons practised long transverse anterior incisions; and Peck further recommended putting up the knee at an acute angle, with the anterior flap everted and the joint widely open. In 1915 I saw some such cases at Brighton, and in 1916 five of the worst cases here were treated by Peck's method. In our experience this is very unsatisfactory. In spite of the widely open joint, treated by continuous or intermittent irrigation, pus tracked behind the joint, the discharges were profuse and dressings very painful. All these cases and those seen at Brighton came to amputation. In two cases the tibia and fibula had become subluxated backwards and upwards. During 1915 I saw some other cases with what might be called *fancy* incisions—such as one 9 inches in length splitting the patella and another with four huge vertical incisions down the front and sides.

Fullerton has advocated early *partial excision with separation of the bones* and free lateral drainage. Our experience of this has not been favourable; one case required amputation, and another died from pulmonary abscess secondary to a bed sore. Theoretically, when carried out in conjunction with the Carrel method it sounds promising.

It should be noted that our cases here present themselves too late for *early* excision, but only in what Sir George Makins calls the *intermediate* period. With regard to this he says:—

"It can only be undertaken with the definite intention of following it at once by an amputation if the procedure is followed by local extension of infection and signs of systemic absorption. It has, however, proved that excision may be a successful alternative when the severity of the general and local signs seems to indicate amputation as the only resource."

When performed for infective arthritis without extensive bone damage, excision of the limited type advocated by Fullerton may be regarded as a method of insuring thorough drainage, as well as obtaining a clean surface by removal of comminuted bone. In many cases some form of irrigation seems valuable.

In 1915 many of us were using normal saline, or weak iodine, or permanganate solutions. Then came Dakin's hypochlorite. Continuous irrigation certainly saved some limbs, but we could not fail to see that the solutions too often poured along the gutters without flushing the whole road, that they ran out through the tubes, or trickled over the surface without reaching the pockets or all the joint pouches.

That is where Carrel's technique is valuable, instilling the antiseptic into every recess; but Carrel is not himself very optimistic about the method as applied to developed sepsis of the knee. In our hospital it certainly appeared to save three joints. But it should also be noted that the Carrel method is not easily carried out in conjunction with that thorough dependent drainage which is a cardinal principle of knee surgery. Of late flavine irrigations have been similarly used.

Statistics.

During the two years covered by this report, 1916 and 1917:—

1.	Total knee-joint cases treated (not including some in which the joint was secondarily affected)	86
2.	Acute septic arthritis	31
3.	,, ,, ,, with bony injury	15
4.	,, ,, ,, without bony injury	16
5.	,, ,, ,, treated by Peck's method	5
6.	,, ,, ,, amputated after ditto	5
7.	,, ,, ,, treated by free incisions and drainage	26
8.	,, ,, ,, amputated after ,, ,,	10
9.	Total amputations (= 17·3 per cent. of total cases, 48·3 per cent. of septic cases)...	15
10.	Mortality (= 12·9 per cent. of total septic cases)	4
	,, after amputation (= 13·3 per cent. of amputations)	2
	,, without ,, ...	2

Cause of death.—Toxæmia, 1; abscess lung, 1; phthisis, 1; tetanus, 1. Early amputation would probably have saved three of these cases.

The knee-joint figures for 1918 up to September show a great improvement on the above.

Summary.

1. In the earliest stage of infective traumatic arthritis an attempt should be made by tapping and distending the joint with some antiseptic, such as flavine or iodoform emulsion, to abort the sepsis. This is being successfully done in France. Good fixation of the limb is essential.

2. When sepsis is established *thorough* drainage is essential; anterior lateral incisions do not suffice; the Peck method is not successful. Suprapatellar, antero-lateral, and postero-lateral incisions should be used in combination.

3. If there is bone damage excision is desirable in most cases, and the bone surfaces may be kept apart.

4. Carrel's method offers the only effective way of introducing an antiseptic fluid into the recesses of the injured joint.

5. With other methods burrowing of pus very frequently occurs, with abscesses tracking up and down the limb and septic absorption; and amputation is apt to be performed too late, when the vital powers have succumbed to the prolonged strain and sepsis has become generalised with a perhaps fatal result.

My acknowledgments are due to the various surgeons associated with me in this hospital, and to Lieutenant-Colonel R. P. Bond for permission to publish this paper.

THREE PLASTIC FACIAL OPERATIONS.

BY R. LAKE, F.R.C.S. ENG.,
SURGEON, ROYAL EAR HOSPITAL, ETC.

DURING the last decade there have been very numerous improvements in plastic operations for altering the shape of the nose and repairing the unsightly results either of disease or injury, and last year a long paper appeared in THE LANCET by Captain Seccombe Hett[1] depicting and describing the methods that are at present in vogue (many of them new) for repairing the effects of war injuries. I am tempted to report three cases in which I have performed plastic operations, one of them only being the result of injury.

CASE 1.—A young man, brought to me by Dr. Thomas Wingrave, was desirous of having his nose so altered as to render his race less obvious. The method adopted is depicted in Fig. 1, and was commenced by separating the ala nasi on one side from the cheek, the incision going through the fold between the ala nasi and the face. The ala nasi was then retracted and the mucous membrane of the septum divided by a curvilinear incision, with the concavity forwards, commencing close to the nasal bone and ending just at the lower anterior margin of the cartilaginous septum. The muco-perichondrium was reflected in both directions, and a strip of cartilage, semicircular in shape and about 3/16 inch in width and the whole length of the incision, was removed. The anterior portion of the nose was then pushed upwards until the two cut surfaces of the cartilage came in contact; it was rotated on itself in an upward direction until the inferior aspect of the nose was at right angles with the upper lip. The cut surfaces of the mucous membrane were joined with a few catgut sutures and the ala nasi sewn in place, and two thin rubber splints inserted just to hold the nose in position during healing. The result was extremely good and quite satisfied the requirements of the patient.

FIG. 1.

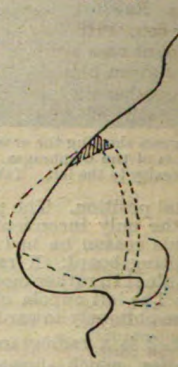

FIG. 2.

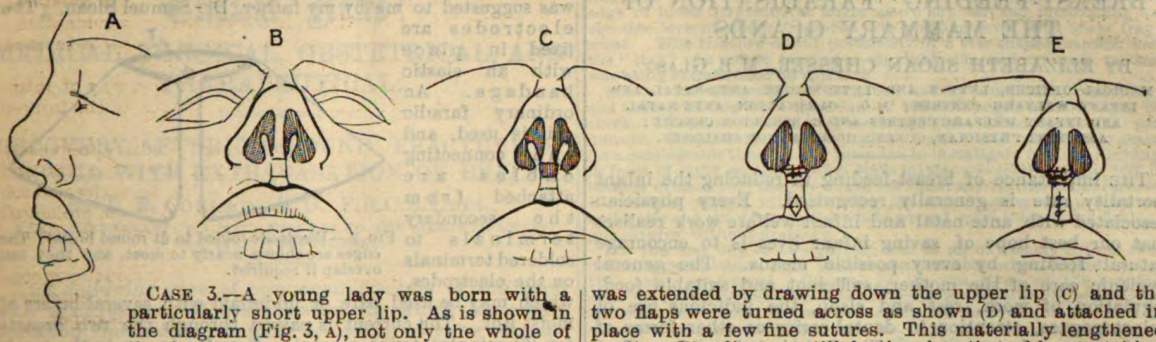
CASE 2.—An officer in the R.A.F., as the result of an accident, had a large depression in the cartilaginous portion of his nose and a gravely deflected septum. (Fig. 2.) The latter I removed by a submucous resection, taking a strip of the cartilage about 1/16 inch square. By means of a long angular knife a bed was made in the subcutaneous tissues in the depressed part of his nose, and the strip of cartilage was slipped in. As, however, this strip was not quite sufficient a second was inserted at a later date, having been taken from the nose of a brother officer who had an ordinary submucous resection performed. This practically restored the nose to its original shape.

[1] THE LANCET, 1917, ii., 892.

FIG. 3.



CASE 3.—A young lady was born with a particularly short upper lip. As is shown in the diagram (Fig. 3, A), not only the whole of the teeth but a large portion of the gum were visible. The various stages of the operation are shown in the figures. The first stage was to make two transverse incisions across the centre of the upper lip, one just at the base of the nose and the other about midway between the lip and base of the nose. Next, two skin flaps were dissected out on either side from the surface of the septum, just within the vestibules of the nose. These are shown dissected out (B). The upper incision was extended by drawing down the upper lip (C) and the two flaps were turned across as shown (D) and attached in place with a few fine sutures. This materially lengthened the lip. The lip was still further lengthened by stretching the lower incision (D) and turning it from being a transverse into a vertical one, and sewing the edges together with a few fine sutures (E). The eventual result was extremely good, the whole of the gum and nearly the whole of the teeth being covered by the upper lip. No scar was visible at all, and the appearance was materially improved.

Cavendish-place, W.

A NOTE ON

THE TREATMENT OF MALARIA BY DISODO-LUARGOL.

BY W. A. MURRAY, M.B., C.M., D.T.M. & H.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS;
AND
R. W. HAROLD ROW, B.Sc., F.L.S.,
PROTOZOOLOGIST TO THE MALARIA DEPARTMENT, 4TH LONDON GENERAL HOSPITAL.

A PAPER on the successful treatment of two cases of malaria by disodo-luargol, by Dr. Louisa Hamilton and Dr. Morna Rawlins, having appeared in THE LANCET of April 6th, 1918, we thought it our duty to try the same treatment on a series of cases in this department, with the results given below.

Altogether six cases have been selected for this investigation, each of which was positive on admission to the hospital—i.e., had asexual parasites in the peripheral blood. The treatment in all cases precisely followed the method described in the above-mentioned paper, save that in two cases it was not possible to carry it through to the end. Blood examinations were made daily in all cases.

Notes of Cases.

CASE 1.—Contracted malaria in G.E.A. in October, 1916; had many relapses from time to time, but was not in hospital. Admitted here 24/7/18 with a temperature of 104° F. and *P. vivax* present in large numbers. The first two doses of disodo-luargol had no effect on either the temperature or the parasites. Unfortunately, after ten days' treatment the patient developed measles, the disodo-luargol course was abandoned, quinine given, and the case was transferred to the M.A.B. hospital at Tooting.

CASE 2.—Contracted malaria in Salonika in September, 1916, had many relapses, and was invalided home. Admitted to this hospital 22/5/18, with temperature 101°, enlarged spleen, and *P. vivax* in fair numbers in the blood. After the first injection the temperature dropped to normal and the asexual parasites disappeared from the peripheral blood. This continued until the seventeenth day, when he had had four injections (the last on the twelfth day), and then the temperature shot up to 105°, though no asexual parasites were found in the blood. An attack of pneumonia followed, and the last three injections of disodo-luargol were not given. He recovered normally, and no further attacks of malaria have as yet occurred. It should be noted, however, that after recovery from pneumonia he was given quinine hydrochloride gr. x daily.

CASE 3.—Contracted malaria in Salonika in August, 1916, and invalided home after many relapses at the beginning of 1918. Admitted here 8/5/18 with a temperature of 104°, a much enlarged spleen, and *P. vivax* present in the peripheral blood. The temperature continued to show a regular, though slight, tertian rise until three days after the third injection, after which it remained normal or subnormal for a week, and did not rise above 99° during the rest of the course. Asexual forms of *P. vivax* remained in the blood until the day after the fourth injection, while three days later *P. falciparum*, both "rings" and "crescents," appeared, though unaccompanied by a rise of temperature, and the crescents remained until some time after the end of the treatment. Eleven days after the completion of the disodo-luargol course *P. vivax* reappeared, and two days later there occurred a frank relapse with a temperature of 104·2°. He was then put on to full doses of quinine and quickly recovered, but was invalided out of the Service for other reasons.

CASE 4.—Contracted malaria in G.E.A. in March, 1917, had several relapses, and returned to England in March, 1918. Admitted here 17/6/18 with temperature 99·8°, anæmia, and enlarged spleen. *P. vivax* present in large numbers. The temperature became normal two days after the first injection, but asexual parasites remained until the second day after the third injection (i.e., for ten days after the commencement of treatment). Asexual parasites reappeared the day after the last injection; the patient's general condition, however, was much improved, and there has been no clinical relapse to date.

CASE 5.—Contracted malaria in Salonika in April, 1917, had many relapses, and was invalided home in May, 1918. He was admitted here 25/6/18 with normal temperature, much enlarged spleen, and enlarged liver. *P. vivax* was present in the blood. One day after the second injection of disodo-luargol his temperature went up to 101° and the asexual parasites, which had never disappeared, showed a distinct increase in numbers. The temperature became normal two days after the third injection, but the parasites have persisted throughout the course, and since.

CASE 6.—Contracted malaria in Salonika, in September, 1916, and was invalided home after many relapses on 24/5/18. He was admitted to this hospital 24/6/18 with a temperature of 100°, spleen much enlarged, and *P. vivax* present in the blood. His temperature has not risen above 99° since the first injection of disodo-luargol, but the asexual parasites remained until four days after the third injection, and reappeared four days after the termination of the course.

Results.

Of the above six cases we have thus been able to carry out the complete treatment in four, with the following results. In one case a clinical and parasitic relapse occurred 11 days after the end of the treatment; in one case the asexual parasites have never disappeared; in the other two cases, although the parasites disappeared, in each case they have reappeared—in one immediately, in one four days after the last injection. Consequently, there is no case in the four in which the disodo-luargol can be considered to have been even temporarily successful, for the presence of asexual parasites in the blood means that a clinical relapse must be regarded as only a question of time. Further, the comparatively long time taken for the asexual parasites to disappear from the blood (16, 10, and 12 days, respectively, in Cases 3, 4, and 6, and not at all in Case 5) does not lead one to anticipate that disodo-luargol is likely to be so effective in the treatment of malaria as quinine, which normally achieves this same result in four days.

There is also a technical point to be mentioned in connexion with the use of this drug. The solution being almost black, it is difficult to be certain that the needle is in the vein, as the back flow of blood cannot be seen, and if the fluid be injected into the surrounding tissues, as happened to us on one occasion, considerable irritation is caused.

In addition to the six cases described above, we have had under observation in this hospital five patients who had partial courses of disodo-luargol at another hospital, and four of these cases have had relapses, both clinical and parasitic, while here.

To summarise our results, we think we have shown that disodo-luargol is no specific for malaria, and in our opinion there are several reasons, both clinical and technical, to render it far less suitable for use than quinine.

In conclusion, we wish to express our thanks to Colonel Sir Ronald Ross, consultant in malaria, and to Lieutenant-Colonel Sir Nestor Tirard, O.C. 4th London General Hospital, for permission to publish these notes.

BREAST-FEEDING: FARADISATION OF THE MAMMARY GLANDS.

BY ELIZABETH SLOAN CHESSER, M.B. GLASG.,

MEDICAL OFFICER, LEYTON AND LEYTONSTONE ANTE-NATAL AND INFANT WELFARE CENTRES; M.O., CARSHALTON ANTE-NATAL AND INFANT WELFARE CENTRES AND CARSHALTON CRECHE; ASSISTANT PHYSICIAN, QUEEN'S HOSPITAL FOR CHILDREN.

THE importance of breast-feeding in reducing the infant mortality rate is generally recognised. Every physician associated with ante-natal and infant welfare work realises that our best hope of saving infant lives is to encourage natural feeding by every possible means. The general hygienic care of the mother, sufficient and suitable food, regulation of work, rest and sleep, the judicious use of galactogogues, attention to dental caries or other forms of sepsis, are each important. The baby's habits also affect the supply of milk. If the infant is allowed to take the breast night and day at irregular intervals the supply of milk is at once jeopardised. There are women, of course, of the perfect nursing type, whose milk seems unaffected by insufficient diet, hard work, even excess of alcohol. The average woman, however, is very largely influenced by physical and psychical causes, and many hundreds of women complain that the "milk goes" in spite of faithfully carrying out the doctor's orders. These are the cases which call for some special treatment, and it was in considering the "failures" amongst my nursing mothers that I conceived the idea of trying electrical stimulation of the mammary glands.

Description of Method.

As a general routine, every nursing mother at my infant centres is advised with regard to diet, her teeth are attended to, and she is recommended to lie down for 1½–2 hours every afternoon when the baby is asleep. This, of course, cannot be managed in all homes, but by insisting on its importance and by advising the mother as to the regulation of her duties, &c., it can be carried out in the majority of cases. The baby is put to the breast every three hours for the first three months of life—viz., at 6 A.M., 9, 12, 3 P.M., 6, and 10, and every four hours from four months old. No night feed is permitted unless in special circumstances. If the baby's gain is not satisfactory a test meal is given according to the usual practice.

Immediately before a feed is due the baby is weighed naked, except for a napkin in case of bladder or bowels acting during the test. He is then given one breast for 12 minutes and weighed again; put to the second breast for

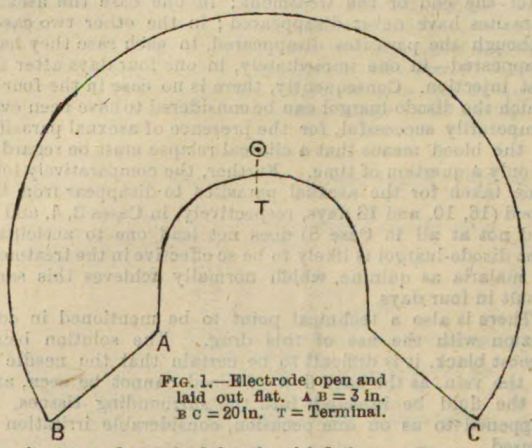


FIG. 1.—Electrode open and laid out flat. A B = 3 in. B C = 20 in. T = Terminal.

12 minutes and weighed for the third time. The amount of milk taken from both breasts is easily estimated. If the milk is insufficient, such a galactagogue as lactagol is ordered, and the mother may be advised to take extra proteid or fat, or both.

If after two or three weeks the infant's gain in weight is still unsatisfactory, my practice now is to stop galactagogues and apply faradisation. This is undertaken at Leyton Town Hall, where our average weekly attendance of mothers is 40–50, and I also send suitable cases from Leytonstone to the Town Hall for treatment.

I use two hollow cone-shaped flexible zinc electrodes. The circular bases fit round the breasts, and they can be adapted evenly to the surface of the glands. This form of electrode was suggested to me by my father, Dr. Samuel Sloan. The electrodes are fixed in place with an elastic bandage. An ordinary faradic coil is used, and the connecting cables are attached from the secondary terminals to soldered terminals on the electrodes, which may be used bare or underlaid with several layers of moist lint. The current is passed through the two breasts for 20 minutes twice a week. I prefer to apply the treatment three times a week if it can be arranged.

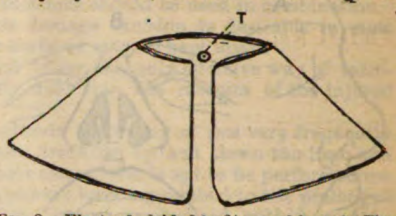

FIG. 2.—Electrode folded to fit round breast. The edges are shown nearly to meet, and they can overlap if required.

The patient feels a gentle tingling, there is no discomfort or pain, and the only inconvenience consists in having to strip to the waist so that the electrodes may be properly applied.

Results.

The results of the treatment have surpassed my expectations. I give below a few typical cases taken from the first series of 12 cases which have had faradic treatment:—

CASE 1.—A poorly nourished infant of 5 weeks suffering from constipation and vomiting after meals; weight 8 lb. ¼ oz. Breast-fed every 2½ hours. Breasts well developed; right nipple very small (a nipple shield was ordered). Physical examination negative. Instructions were given with regard to suckling, and the mother was cautioned against allowing the baby to have the milk too fast. The child was to be fed every three hours and no night feed allowed. Test feed; 2¼ oz. was the total obtained from both breasts. In four weeks the child had gained an average of only 1 oz. per week. Electric treatment twice a week was then ordered and this was continued for five weeks. The average weekly gain became 4 oz. per week, and the two weeks following the cessation of electric treatment the gain was 5 oz. per week. The mother declared that after two or three treatments she felt stronger, "the milk flowed into the breasts and poured away." The baby became contented, the vomiting ceased, and constipation diminished.

CASE 2.—Child of 4½ months; weight 12 lb. 7 oz.; had not been thriving. At the second attendance the following week, the child weighed 12 lbs. 4½ oz.—a loss of 2½ oz in spite of the usual instructions. Test feed demonstrated that the child was having only 2 oz. of milk from the mother. Breasts flabby, no sensation of fullness at feeding time. Electric treatment was therefore ordered twice weekly. In two months the child gained an average of 4 oz. per week. Baby contented and thriving, formerly cried continually. After two treatments the mother said she felt the breasts fuller, and this improvement continued and was maintained after cessation of treatment.

CASE 3.—Child of 5 months; 12 lb. 3 oz. Before electric treatment was started it was only possible to draw off a tablespoonful of milk at feeding time. Baby was having two bottles of 6 oz. daily to supplement breast-feeding. After four weeks of electrical treatment baby required only 3 oz. of humanised milk once daily in addition to breast. Average gain 4¾ oz. per week.

CASE 4.—Child of 3 months; 9 lb. 13½ oz.; poorly nourished, not gaining. After two electric treatments the mother said: "The milk now runs in when I nurse baby, and did not do so before." After nine electric treatments: "Baby quite satisfied, ample milk." Average gain 3¾ oz. weekly, in spite of the fact that the child had an attack of bronchitis during treatment.

Of a first series of 12 consecutive cases, 2 must be eliminated, as they were only able to attend for electric treatment twice. Of the remainder, 5 had from 8–10 treatments, 5 were sufficiently improved in from four to seven treatments. In every case the child improved in health and an average gain in weight of 3½ to 5 oz. a week was maintained. In 6 cases the average gain in weight prior to beginning electric treatment was 1½ to 2 oz. a week; in 4 cases the treatment was started at the first or second attendance of the child at the clinic, as the test meal showed that the infant was having less than half the required amount of milk from the breasts and the case seemed urgent.

I had intended to send a specimen of mother's milk in every case to a laboratory for analysis before and after treatment, but in most cases only a teaspoonful to a tablespoonful of milk could be extracted from the breasts which, when sent to the laboratory, was found to be useless for any complete examination. In giving faradic treatment it may be necessary for a couple of weeks to supplement the mother's milk by cow's milk or artificial food. This interferes with the experimental part of the work, but it is interesting to find that with several treatments the milk is so improved in quantity and quality that extra feeding can gradually be reduced and given up entirely.

I have to thank Major J. F. Taylor, medical officer of health of Leyton, for allowing one of his health visitors, Nurse Dodds, to carry out the bi-weekly treatments under my directions.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

RECOVERY AFTER COMPOUND FRACTURE OF SKULL WITH EXTRAVASATION OF BRAIN.

BY T. E. COULSON, M.D., F.R.C.S.EDIN.,
TEMP. LIEUTENANT, R.A.M.C.; SURGEON TO THE MERTHYR GUEST HOSPITAL, TEMPLECOMBE.

THE following case of compound fracture of the skull with extravasation of brain matter, in which immediate operation resulted in complete recovery, may be of some interest:—

On June 13th, 1918, a boy, aged 9, was riding in a wagon in a hay-field with two girls, when the horse "bolted." One of the girls jumped out over the side of the wagon, the wheel went over her leg, and she sustained a compound fracture-dislocation of the ankle-joint. The other girl became frightened, seized the child and threw him out of the wagon over the side, both wheels going over his head. She herself then climbed out over the back and escaped unhurt.

Photograph of patient on June 26th, 13 days after operation.

This happened at about 4 P.M., and the boy was admitted to the Merthyr Guest Hospital at 4.30. When I saw him at 4.45 he was semi-conscious, vomiting almost continuously, blood and cerebro-spinal fluid coming freely from both ears. There were two wounds, each about the size of a threepenny-piece, on right side of head, one about 2 inches above right ear and the other about halfway between right ear and right eye; from the former of these brain matter was oozing in considerable quantity. There was a linear depressed fracture on both sides of head running from before backwards. Temperature subnormal; pulse 90 per min.; pupils dilated and equal; no paralysis of face or limbs.

I operated at 5 P.M. After shaving the head and painting it with chloroformum iodi an incision was made from a point 1½ in. behind right ear vertically upwards for 3 in., then directly forwards for 5½ in. to a point 1½ in. above centre of right eyebrow. This curved incision ran ½ in. above line of depressed fracture on this side. At posterior end this fracture was star-shaped, one "limb" of star pointing downwards in front of right ear (from this brain matter was oozing), one pointing behind right ear, one upwards and backwards, and the main fracture forwards to the point 1½ in. above centre of right eyebrow. The centre or "body" of the star was missing altogether, but was eventually found beneath the parietal bone, between it and the dura. It was withdrawn and discarded.

Attention was now turned to the main depressed fracture on this side. The lower fragment was depressed beneath the upper, so that the latter overhung the former by about ¼ inch. I therefore cut away with bone forceps a wedge-shaped piece of upper fragment about its centre and, introducing an elevator, lifted up lower fragment on a level with upper. There followed a good deal of hæmorrhage, which, however, ceased in a short time. The fracture on left side extended from the point 1½ in. above centre of right eyebrow, where fracture on right side ended, backwards to the left to a point 3½ in. above left ear, and then directly backwards for 1½ in. I made an incision about ½ in. below line of this fracture. The illustration shows line of incision on this side.

On the left side upper fragment was depressed beneath lower fragment to extent of about ¼ in. I applied a ¾ in. trephine to edge of lower fragment at angle above left ear, and introducing an elevator levered upper fragment into position level with lower fragment. This fracture ended posteriorly in a star-shaped manner, but the "star" was not so marked as on right side, and no brain matter was being extravasated on this side.

The various manipulations described had by now taken some time, and the boy having lost a good deal of blood he began to show signs of shock. The pulse became very weak and fast; it had risen to 130 per minute. Respirations became "catchy," and would occasionally cease for a considerable time. I had intended to investigate fracture running in front of right ear from which brain matter was coming away, but it became evident that the boy would not stand any further procedure, so I contented myself with swabbing the brain matter away with an antiseptic and stitching up the whole wound with interrupted fishing-gut sutures, without drainage.

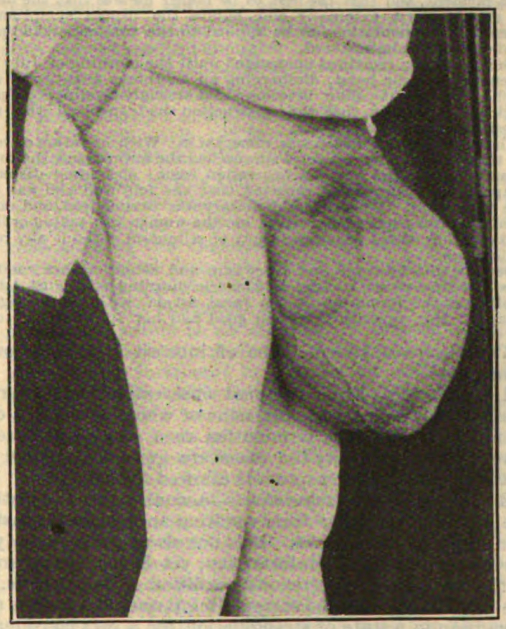
For the first day or two patient was in an extremely critical condition, semiconscious, very violent and irritable when roused; pulse 120; temp. subnormal. Calomel gr. iii. was given on the evening after the operation and after this had acted on the following evening he became much quieter and more rational. On June 16th he was able to answer questions rationally, took his food well, and began to have control over bladder and rectum. The stitches were removed on June 22nd and all bandages taken off on the 26th. On June 23rd, 24th and 25th there was very slight watery blood-stained discharge from both ears and a very slight amount of epistaxis on June 25th.

The boy is now up and about and appears perfectly normal in all respects with the exception of slight deafness in left ear.

RADICAL CURE OF A VERY LARGE INGUINAL HERNIA.

BY C. P. G. WAKELEY, M.R.C.S. ENG., L.R.C.P. LOND.,
TEMPORARY SURGEON, R.N., H.M. HOSPITAL SHIP "GARTH CASTLE."

Dr. J. A. Browne's case of large inguinal hernia,[1] which was reported in a recent number of THE LANCET, aroused my interest because I had a very similar case under my care several years ago, when I was house surgeon to Mr. Albert Carless at King's College Hospital. The enormous size of the hernia can be seen from the photograph; it was a left oblique inguinal hernia and descended to the patient's knees, causing great inconvenience in walking. The patient, aged 50, was a very tall man. He stated that he had noticed the rupture for over 10 years. The hernia could be reduced with difficulty, but could not possibly be controlled by any form of truss or bandage. The penis was completely hidden,



and could only be located at the bottom of a small depression at the upper part of the swelling. Micturition was difficult at times. The opening of the canal admitted four fingers easily. The patient was kept on his back with the foot of the bed raised for two weeks previous to the operation. A radical cure was performed; the left testicle, which

[1] THE LANCET, 1918, ii., p. 106.

had atrophied considerably, was excised and the inguinal canal completely closed. A large portion of the skin of the scrotum was removed. Quite 12 feet of small intestine were found in the hernial sac, together with most of the pelvic colon. The hernial sac was completely excised and the wound healed by first intention. I saw this man a year after the operation, and he stated that the result was excellent and that he had experienced no trouble at all. It seems to me that with a hernia of such a size and duration the best form of treatment is to excise the testicle, which is often functionless, and completely to close the inguinal canal.

A CASE OF

STRANGULATED INGUINAL HERNIA WITH EXTERNAL RUPTURE OF THE SAC.

BY HAROLD F. RENTON, M.D., B.S.LOND., M.R.C.S., L.R.C.P.

ALTHOUGH it is usually taught that a hernia of the bowel presenting through one of the common abdominal orifices and in a strangulated condition may rupture and discharge its contents externally, yet no such condition had come before my notice until I was called upon to treat the following case.

On July 19th, 1917, I was asked to see a lady in the country with a severe attack of vomiting which nothing relieved. On entering the room I smelt a strong fæculent odour. The patient, aged 50, was in bed propped up with pillows; breathing short and painful. The face was drawn and anxious, pupils dilated, tongue dry and coated with brown fur. At intervals she was seized with a violent attack of vomiting; vomited matter brownish fluid and typically fæcal. Pulse rapid and almost impalpable; temperature subnormal. The abdomen was very distended and tympanitic; marked peristalsis, localised to umbilical area and typically "ladder" in character, indicating the obstruction was involving small intestine. In right inguinal region was a large swelling, black in colour, from which came the powerful fæculent odour. The swelling, surrounded by an area of inflammation, was tympanitic to light percussion.

A diagnosis of strangulated inguinal hernia was made, and it was clear that the hernial contents were gangrenous. It was elicited that the rupture had been present four years; it had not given rise to any pain or discomfort until onset of present acute attack some four weeks previous to my visit, when she was seized with acute pain in the swelling. Absolute constipation followed, as well as persistent vomiting, which had existed during the whole of the four weeks.

It was obvious that patient was too ill to undergo any operation at that moment, and that the best to be hoped for was that the hernial sac should burst externally and relieve the urgent symptoms. I ordered hot fomentations to be applied to the tumour, and a limited fluid diet to be administered.

The condition remained unchanged until the morning of July 23rd, when the tumour burst, discharging an enormous quantity of semi-fluid fæces, bright yellow in colour and strongly alkaline. Thus the original observation that the obstruction had involved the small intestine was supported.

The prompt amelioration was remarkable. With cessation of vomiting the pulse and temperature approached the normal and the tongue became clean. The anxious expression went; abdominal distension disappeared. The patient reported that she felt well and was quite free from pain. A liberal fluid dietary was commenced, and on the third day after rupture of hernial sac the woman was taking ordinary food together with a generous supply of stimulant without any return of sickness.

Despite this, however, and every care and attention, her condition slowly became worse, and she died on the morning of August 1st, one week after the formation of the fæcal fistula, with all the signs of collapse. Her appetite remained good and her spirits bright up to the end.

This case would seem to be of interest for the following reasons:—

1. *Its rarity.*—From personal observation, and after discussion with medical friends, none of whom had seen a case, I conclude that such a termination to a strangulated hernia is very rare. Probably the cases are generally handed over to the surgeon before rupture is allowed to take place.

2. *Duration of strangulation.*—According to the patient, she had been suffering from vomiting and absolute constipation for some four weeks. It is not always wise to rely too much upon a patient's information, yet from the appearance of the hernia, the gangrenous condition of its contents, and the inflammation of the surrounding tissues the bowels must have been in a state of strangulation for a very considerable period. Remembering how rapidly collapse and death supervene in a case of unrelieved intestinal obstruction, the long duration of the woman's suffering becomes all the more remarkable.

3. *Cause of death.*—It had been hoped that after rupture of the hernial sac, and with relief of the acute symptoms, the woman's condition might have improved sufficiently to enable her to undergo an operation for closure of the fæcal fistula, but despite a generous dietary and free stimulation she steadily lost ground. The colour of the fæces and their strongly alkaline character showed that the portion of small bowel involved in the hernia was at a very high level. It seems clear that death was due to the cutting off of an enormous portion of the absorptive area of the intestinal tract. But for this fact no doubt is entertained that the woman's life could have been saved.

It will naturally be asked why I did not at once open the hernial sac, and some doubt may be expressed as to the possibility of any patient living so long with obstruction at such a high level in the bowel. As a result of my first examination I came to the conclusion that the woman would only last a few hours and that no treatment could postpone the end. The local treatment was employed with the sole intention of doing something to relieve her suffering. Two methods of procedure offered themselves had I decided to operate. First, by general anæsthesia, which would certainly have hastened the end; and, second, by plunging a knife boldly into the sac. As it had not been determined what was the cause of the obstruction, and as this might possibly have been due to the sudden entry into the sac of some new and healthy organ, a haphazard incision might have resulted in injury of a grave nature, to an otherwise healthy organ, and the last state of the patient have been, if possible, worse than the first.

It is certainly more difficult to give a satisfactory answer to the second question. Unfortunately, I have not ready access to the literature on the matter, although it must be admitted that the general teaching is that the higher the level in the bowel at which lies the point of strangulation, so much the more severe is the shock, and rapid the end.

My deductions as to the possible position were based upon clinical observation before rupture of the sac—namely, the site and character of the peristalsis, and later, upon the fluid, yellow nature, and strongly alkaline reaction of the discharges when rupture had taken place. In any case, it would be interesting to hear expert opinion on this point.

Doncaster.

New Inventions.

A NEW RUBBER MASK SPECIALLY DESIGNED FOR GENERAL ANÆSTHESIA WITH ETHYL-CHLORIDE AMPOULES.

AN ingenious apparatus for general anæsthesia with exact dosage of ethyl-chloride as gauged for each particular case has been brought to my notice. It is so constructed that the whole of the ethyl-chloride contained in each graded glass ampoule is administered gradually, fully, and without loss. The whole apparatus consists of one piece of rubber; it is therefore pliable, easily carried, convenient to handle, and thoroughly sterilisable. The interior of the mask communicates through a short wide-bore tube by a T-joint with another tube running at right angles. One limb of the T receives the ampoule, the other limb is closed at the end, and is armed in the centre of its blind end with a pin projecting into the centre of the lumen. This limb receives the umbilicated end of the glass ampoule of ethyl-chloride. When the ampoule is pressed home the pin first impinges on and then perforates the umbilicated end, and the ethyl-chloride vapour streams out along the short wide tube on to a gauze pad suitably placed and held in position by a rubber band. The vapour diffuses throughout this pad, from which it is breathed by the patient. This pad is easily removed after each case and replaced by a fresh one. The rubber band keeps it lightly but firmly in position. There is no waste of ethyl-chloride and the dosage is exact. If one ampoule proves insufficient, it can, when exhausted, be quickly supplemented by another full ampoule of any desired capacity, the change requiring a minimum of time or trouble. If before introduction the glass ampoule is slightly moistened, no difficulty will be experienced in pushing it smoothly into the tube to the full extent required to cause the pin to puncture it at the desired moment. I have tried this mask on myself and find that it fits quite comfortably.

Reviews and Notices of Books.

War Wounds of the Lung: Notes on their Surgical Treatment at the Front. By PIERRE DUVAL. Authorised English translation. Bristol: John Wright and Sons, Ltd. 1918. Pp. 100. Price 8*s.* 6*d.*

WE have already noticed (THE LANCET, Sept. 8th, 1917, p. 393) Dr. Pierre Duval's admirable monograph, "Les Plaies de Guerre du Poumon," and commend it again to our readers in its English guise. A new chapter added to the translation brings the author's experience up to January of the present year, and concludes with a sentence epitomising his whole teaching: "Lung wounds are analogous in every respect to any other battle wound, and must be treated according to the same general principles."

The translation emanates from the 36th Casualty Clearing Station, B.E.F., which has been in close association with the Auto-Chir. No. 21, Armée Française, of which Duval is médecin-chef, and the dedication gives occasion for an expression of that mutual esteem and admiration which is making the Anglo-French entente a real and permanent thing. Both text and illustrations are well done and the external trappings of the book very pleasing.

---

1. *The Treatment of War Wounds.* By W. W. KEEN, M.D., LL.D., Emeritus Professor of Surgery, Jefferson Medical College, Philadelphia. Second edition. London and Philadelphia: W. B. Saunders Company. 1918. Pp. 276. Price 8*s.* 6*d.*
2. *American Addresses.* By Sir BERKELEY MOYNIHAN, M.S. Lond., F.R.C.S. Eng. London and Philadelphia: W. B. Saunders Company. 1917. Pp. 143. Price 7*s.* 6*d.*

TWO attractive little books published in the United States of America will help to bring recent remarkable developments in war surgery before the medical world of the great republic of the West.

1. Dr. Keen has enlarged his bird's-eye view of English and French surgical practice on the Flanders front. He has collected his material from many sources, and the volume will be read with interest as the considered judgment of a veteran surgeon, whose detachment allows him to see relative values in a mass of new and absorbing work. The short bibliographies attached to some of the chapters may give a useful hint for the war surgeon's library.

2. Sir Berkeley Moynihan has collected in one volume the addresses on gunshot wounds and injuries delivered last autumn in Chicago and other American cities, giving his own conclusions on the treatment of the many new phases of surgical diseases for the benefit of his American colleagues. We commented at the time of their delivery on these crisp and enlightening summaries, and commend them in their present form to the reader's notice.

La Suspension dans le Traitement des Fractures: Appareils Anglo-Américains. By P. DESFOSSES and CHARLES-ROBERT. Preface by M. PIERRE DUVAL. Paris: Masson et Cie. 1918. Pp. 172. Price 4 frs. 40.

THIS latest fascicle of the Collection Horizon is an admirable example of the war manual at its best. M. Desfosses is surgeon to the *Hôpital britannique* in Paris, and M. Robert is a pupil of Major Sinclair who has applied the latter's methods in the famous Auto-Chir. 21 to which M. Duval is attached. The manual starts with a description of the suspensions known by the names of Blake, Sinclair, and "Balkan," going on to their detailed application to fractures of the extremities. Each stage in the application is abundantly illustrated. M. Duval in his preface frankly acknowledges his preference for the Thomas splint, but many other ingenious forms appear in the text. The little book is a safe technical guide to the successful treatment of gunshot fractures of the limbs.

An Index of Prognosis and End-Results of Treatment. By Various Writers. Edited by A. RENDLE SHORT, M.D. Lond., F.R.C.S. Eng. Second edition. Bristol: John Wright and Sons, Ltd. 1918. Pp. 770. Price 30*s.*

WE are glad to see a second edition of this useful work of reference, to which fresh material has been added in view of recent experience on tetanus, gas gangrene, septic peritonitis, and gunshot wounds. The account of tropical diseases has been rewritten by Sir Leonard Rogers. We miss any allusion to the now very important disease, trench fever, but the editor disarms criticism in regard to possible omissions by pleading that he and many of the contributors are serving overseas, and the same war conditions which are vastly extending our knowledge of certain groups of diseases are making it exceedingly difficult to ascertain the "end-results" which are the subject of this book. The appearance of a new edition as soon as possible after conclusion of the war will be very welcome. The publishers' share in the book is all that could be desired.

An Introduction to the Physiology and Psychology of Sex. By S. HERBERT, M.D. London: A. and C. Black, Ltd. 1917. Pp. 136. Price 3*s.* 6*d.*

THE author has already expounded with some success the first principles of heredity and of evolution to a lay audience, and at the desire of the Feminist Club of Manchester has now endeavoured to do the same in a field where many others have failed before him. In this he has been largely successful. The elementary facts of the biology and physiology of sex are rendered in the "simple yet scientific manner," which the author has set before himself. In sex psychology "facts" are less easy to define, and some of the simple assertions made will require modifying in the light of present-day experience. It is, we believe, misleading to state boldly, "To man love is an episode; to woman it is her whole life"—and the statement is not altogether in harmony with the forecast, in the concluding pages, of a new sexual order with which we are in general agreement.

The Practical Medicine Series. Vol. I., General Medicine. Edited by F. BILLINGS, M.S., M.D., assisted by B. O. RAULSTON, A.B., M.D. Series 1918. Chicago: The Year Book Publishers. 1918. Pp. 621. Price $2.25.

THIS is the first volume of a series of eight, to be issued at about monthly intervals, covering the entire field of medicine and surgery, and primarily intended to keep the general practitioner in touch with the newest developments of his science and art. The medical literature of America, England, France, and Switzerland is abstracted for this purpose, and as far as work on this side is concerned, abstracted with care and discretion. We can therefore recommend the series to any who are prepared to face a yearly reading of some 5000 pages in order to keep abreast with current medical thought.

Nutrition and Clinical Dietetics. By HERBERT S. CARTER, M.A., M.D.; PAUL E. HOWE, M.A., Ph.D.; and HOWARD H. MASON, A.B., M.D. Philadelphia and New York: Lea and Febiger. Pp. 646.

THE authors of this ambitious book, who are all members of Columbia University, New York, start from the assumption that dietetics must be deduced in part from an accurate knowledge of the chemistry of foods and of nutrition, but in greater degree from the results of actual clinical experience. Their qualifications render this combined method possible within the covers of a single book inasmuch as the first-named author is an associate in clinical medicine, the second an assistant professor of biological chemistry, and the third an instructor in diseases of children. And the result is a book which will be of real value to the clinician at a time when nutritional problems have largely to be solved on the basis of what is possible rather than what is theoretically advisable. The book is divided into four parts, the first dealing generally with foods and normal nutrition, in which the subject of energy requirement is fully treated; the second takes the various foods seriatim and discusses their particular values and deficiencies; the third is a short part devoted to feeding in infancy and childhood; and the fourth part goes into the dietaries of various diseases and the special régimes proposed for them. An appendix contains tables of food values arranged in a variety of useful ways. The authors, although basing their conclusions largely on their personal experience, are careful also to include due notice of the work of others—e.g., Bardswell's and Chapman's diets in tuberculosis, Joslin's useful résumé of Allen's starvation treatment for diabetes. Their remarks on metabolic problems are always interesting and often stimulating, as in the sections on the causes of

obesity, the food adapted to brain workers, and the appropriate diet for athletes. In the latter connexion they note how easy it is to acquire the habit of large eating and of continuing it after the necessity for it is past, as in the case of "farmers'" indigestion, which they suggest is due to persistence in a large dietary during off seasons, when little muscular effort is demanded. All through the book the influence of new thought on old problems is clearly discernible. The work cannot fail to be a useful vade mecum to the modern practitioner.

"One Thing I Know, or the Power of the Unseen." By E. M. S. London: John M. Watkins. 1918. Pp. 146. Price 3*s.* 6*d.*

IT would not be difficult to ridicule E. M. S.'s autobiographical account of her illness and recovery through the devoted treatment of an unseen spirit whom she calls "Dr. Beale," and yet its evident sincerity wins respect. We are told that E. M. S. had been bedridden for 15 years, and for the past six years had been unable to sit up in bed for more than two minutes without knocking herself up for six or nine months. Exertion such as this made her utterly exhausted, and her pulse rose to 140. She sometimes required food 30 times in the 24 hours, and so on. She had consulted over a dozen medical men, had taken tonics, sedatives, glandular extracts, had Nauheim and Kneipp cures, massage, rest cures, hypnotism—all to no purpose. The "earthly" medical man, whose report is given, states that there was no indication of insanity or hysteria, but, as we read the case, the disorder was clearly functional.

The story as told is no uncommon one in practice. The gravity of the matter lies in the fact that legitimate medicine failed, whilst recovery followed under the influence of several women with so-called psychic powers. Such cases are worth careful scientific study. It is surely a reproach to medicine when patients such as these remain ill for long periods of time and recover by means such as are here described.

Dr. Beale, we are told, died many years ago, and after a deep sleep devoted himself to work on earth, using the body of a Miss Rose and other persons possessing "psychic" qualities. Dr. Beale also had a kind of home in the unseen world where he treated recently arrived spirits who were in trouble. His treatment was interrupted by his being suddenly called to higher spheres for a course of instruction. Fortunately, he left a useful locum-tenent, "Dr. Prentice." We are also told how the possessing spirit is apt sometimes to forget the body of the instrument and "the doctor has been known to ask if his trousers were muddy or his tie straight, and has really been annoyed to find upon looking down that he had on petticoats and a lace collar"!

The fact remains that the patient recovered, and the important question is how it came about. We find two methods of treatment which are novel. By means of magnetic massage Dr. Beale (i.e., Miss Rose) drew out of the body "bad stuff" and threw it away, as it were, from the tips of his fingers. When he was called away during her convalescence he left behind a "psychic battery," upon which, however, she drew so extravagantly that she nearly had a relapse. The remainder of the treatment appeared to consist of massage and exercises continued for months, then gradually she was taught to use her leg muscles and at last to walk. Within two years she was well. There are many other remarkable things in the book, which is vividly written and profoundly interesting, as showing what the "will-to-believe" can do when uncontrolled by experience or the critical faculty.

The Internal Secretions: their Physiology and Application to Pathology. By E. GLEY, M.D., Professor of Physiology in the College of France. Translated and edited by MAURICE FISHBERG, M.D., Clinical Professor of Medicine at New York University. London: William Heinemann (Medical Books), Ltd. 1918. Pp. 241. Price 10*s.*

AT a time when the paramount importance of the endocrine glands, both in normal and abnormal states of the body, is beginning to be realised, while the actual practice of organotherapy remains largely empirical, the appearance in English form of Professor Gley's scientific and critical study is cordially to be greeted. Gley can be trusted to state with equal precision both what we know and what we do not know, and Dr. Fishberg has almost confined himself to rendering the original in fluent English. The chapter on the normal reciprocal relations between thyroid, pancreas, and adrenals is one of the most interesting. References are given throughout the book which render further study easily possible.

Studies from the Rockefeller Institute for Medical Research. Reprints. Vol. XXVII. New York: The Rockefeller Institute. 1917. Pp. 559.

THE titles of this most recent volume of reprints show the prevalent direction of pathological and bacteriological research. Papers by H. Noguchi and others on the staining reactions of various spirochætes are followed by a series of articles on poliomyelitis under the names of S. Flexner and his pupils. Clinical studies are included on the toxæmias of pregnancy, and on metabolism in lymphatic leukæmia. An ingenious mathematical study from Hospital No. 21, at Compiègne, deals with the rate of healing in wounds.

Transactions of the American Surgical Association. Vol. XXXV. Edited by JOHN F. BINNIE, M.D. Philadelphia: William J. Dornan. 1917. Pp. 616.

THE Transactions of this lively association continue to reach us with a regularity and a prodigality of material which can only excite jealous admiration in these times. Besides the usual clinical papers we note excellent biographies of two great surgeons, Victor Horsley and Vincenz Czerny. Of unusual interest is a topographical analysis by Dr. Edmond Souchon, of New Orleans, of America's original contributions to medical science. We learn, for instance, that Dr. E. B. Walcott, of Wisconsin, performed the first nephrotomy; that Dr. A. D. Bush, of Vermont, determined a 10 per cent. mental deficiency in tobacco users; that Dr. F. G. Novy, of Michigan, first cultivated trypanosomes. Devotees of medical history will refer to his original article.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

SUBSCRIPTIONS TO THE SECOND APPEAL.

THE following subscriptions have been received up to Monday last, Sept. 9th:—

	£	*s.*	*d.*
Dr. C. A. Rayne	5	5	0
Dr. Robert J. Carlisle ...	2	0	0
Sir Alfred Pearce Gould (monthly)	5	5	0
Dr. Dundas Grant... ...	10	10	0
Mr. W. J. Shepperd ...	0	10	6
Mr. J. V. C. Denning ...	1	1	0
Dr. Edward Byrd	1	1	0
The Sunderland Pharmaceutical Association*	16	17	6
American Red Cross Commission for Belgium	200	0	0
Capt. A. P. Thom, R.A.M.C.	1	1	0
Mr. D. T. Jones, M.P.S.	1	1	0
Mr. E. Spencer Evans (monthly)	0	10	0
Dr. J. B. Davey	1	1	0
Dr. J. Auriol Armitage†	5	5	0

* Per Mr. Cuthbert Hodgson. † Second donation this year.

The munificent gift of £200 from the American Red Cross has been received through Mr. Ernest P. Bicknell, the Commissioner for Belgium, who writes: "This contribution is for the month of September, 1918, and is from the Commission for Belgium of the American Red Cross. A monthly contribution of the same amount will be made for the remaining months of the year." This timely and open-handed grant should inspire further British contributions in order that increased monthly payments may be made to Belgium.

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W. 1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE LATE DR. C. E. GLASCOTT.—Charles Edward Glascott, M.D., C.M., F.R.C.S. Edin., died recently at his residence, Budleigh Salterton, Devon. He was born in 1847 at Constantinople, and received his medical education at Edinburgh University. For 35 years Dr. Glascott was honorary surgeon to the Manchester Royal Eye Hospital. He was formerly president of the Manchester Medical Society, and lecturer and examiner in ophthalmology at Victoria University, Manchester. Since his retirement he had resided at Budleigh Salterton.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 14, 1918.

The State and Research.[1]

THE members of the Committee of the Privy Council for Scientific and Industrial Research have a heavy task in front of them, but in their third annual report, issued last week, it is shown that steady and valuable progress is being made along many important lines. It is not surprising to learn that the past year has seen a great extension of the work of what is now the important State Department of Scientific and Industrial Research, when the scope of its activities is considered. Out of the fund of £1,000,000 voted by Parliament in order to enable the Department "to enter into agreements with new industrial research associations for the payment of grants over a period of years" there has been guaranteed to the British Scientific Instrument Research Association an expenditure of £36,000 on approved research during the next five years. During the same period a grant of £1500 a year has been awarded the British Photographic Association; and research associations, having as their object the betterment of the cotton and woollen industries, have received similar awards provided that the firms concerned subscribe equal sums towards the same end. We mention these matters because, taken with what follows, they illustrate the wide range of the activities of the Department.

The Committee early in the year assumed responsibility for the maintenance and development of the National Physical Laboratory, and they have approved extensions of the laboratory which will enable the staff to undertake the testing of the higher grades of chemical glass and the testing of all clinical thermometers, whether for military or civilian use. Amongst the researches of direct medical interest is one on mine-rescue apparatus, the progress of which is being watched by the Medical Research Committee, and an obviously related research is that on respiration apparatus. It is of interest to mention that one result of these researches has shown that a man's respiratory behaviour when oxygen is administered during manual work is dependent on his physical condition. Following up this opening Dr. HENRY BRIGGS, of the Heriot-Watt College, Edinburgh, has been able to devise a method of measuring physical fitness and stamina which has been tested on a considerable number of men chosen chiefly from the Army and the mines. Apart from its bearing on the selection of men for mine-rescue teams, the method has a wider interest in affording a new means of ascertaining a man's value for the Army. The War Office authorities have recognised this fact, and the first physical testing station has been established in Edinburgh. A further interesting development of Dr. BRIGGS'S work has been an improved system of supplying oxygen for Army purposes, in which the question of the storage and supply of liquid and compressed oxygen and other gases has received particular attention.

Another pressing matter which has come before the Department has been the improvement and wholesale extension of cold storage systems, with a view to the preservation of the thousands of tons of food which are annually lost by decay before they can be sent to market. It was agreed, most wisely we think, that the investigations in this direction could be more suitably conducted by the State than by any industrial research association, and the Food Investigation Board of the Department has them in hand. The work has been well begun and a substantial sum awarded for pursuing this most important direction of research. Experiments on the freezing of fish are being conducted at North Shields, and an experimental and demonstration plant for the freezing of fish has been set up in Billingsgate Market. Another committee has been appointed to investigate on similar lines the processes for preserving meat, fruit, and vegetables, and the laboratories at Cambridge have been requisitioned for the purpose of conducting investigations into the physiology of fruit and vegetables at low temperatures and into those diseases which attack fruit in storage. Heat insulation and the influences determined by hygrometry form yet another interesting and important branch of cognate inquiry, the results of which would preserve for our use the kindly fruits of the earth, so that in due time we may enjoy them. The Board of the Department has also within its ken certain matters connected with the use of oils and fats, a veiled reference doubtless to the edible fats—margarine and butter substitutes. "Events," the report states, "have justified the rapid decisions which we took in the summer of last year, while experience has shown that the appointment of a responsible director to organise a group of researches of national importance, assisted by an advisory board of distinguished men of science and affairs, greatly facilitates prompt action and the proper coördination of all the work in accordance with a definite scheme. Research work, like other forms of creative activity, will not flourish under committee rule." Could a more scathing criticism be levelled at our past commercial methods than is contained in this pregnant sentence? The report deals with important technical problems, and while we have narrowed our review to those questions which claim obviously and particularly the attention of the medical profession, we urge such of our readers as have the necessary time to study the whole short document. It affords valuable reading because of the strong and serious effort which it discloses to bring about reforms which have long been urged upon us by our scientific leaders, and fully confirms the Report of Sir J. J. THOMSON'S Committee "to enquire into the position of natural science in the educational system of Great Britain," Professor STARLING'S review of which appears in the subsequent pages of this issue.

Annotations.

"Ne quid nimis."

WAR NEPHRITIS.

THE growth of a child is notoriously discontinuous, and it often happens that knowledge of a new disease advances sometimes rapidly, sometimes with tiresome slowness, while apparently the same amount of work is being put into it by competent investigators. A striking example of this is given by war nephritis. The recent report of the Medical Research Committee is largely of a negative character, throwing little or no further light on the causation of the disease. Interesting additional information is, however, incidentally given.

The *first* part of the report is drawn up by the Committee on War Nephritis working in France. This shows that although the first rise in the incidence of nephritis occurred in the spring and early summer of 1915, after that time most cases occurred in the winter, the temperature curve varying inversely with the rate of incidence so closely that it can hardly be without significance. It is gratifying to learn, however, that the total numbers have never reached a figure that could be considered of importance to the strength of the Army. As each group of the new army went to France there was a rapid and uninterrupted rise in the incidence of cases in that group, reaching its highest point in about six months, after which a fall occurred, reaching its lowest point the following summer. After that the incidence curve of the group followed closely that of the whole Army. The suggestion is that the individuals naturally prone to nephritis were first attacked, leaving a more or less homogeneous residue. We might add that these results also suggest that though climatic conditions were not responsible for producing the outbreak, since it did not start till after the severe winter of 1914–15 was past, they have played a considerable part in modifying the incidence of the disease once it had started. Fortunately, the death-rate has remained low. The average annual mortality for all cases was 0·93 per cent. During 1916 only two officers died from nephritis, and none during 1917. The Committee could not find that diet, chlorinated water, metallic poisons, intestinal intoxication, previous renal disease, or illness immediately prior to the nephritis had any influence. They comment on the occurrence of cases in hospital orderlies who had never left their base hospitals, and note that the disease was not limited in its incidence to the older men. They also conclude that the severe exertion and fatigue undergone during training at the base played little or no part in its etiology.

The *second* part of the report is a clinical study by Captain O. L. V. de Wesselow and Captain H. MacLean, who found that in a large proportion of the cases the onset was comparatively insidious. The first indication in those doing heavy manual work was increasing shortness of breath; in those leading a sedentary life headache was the first symptom. The œdema tended to clear up rapidly, its disappearance being usually accompanied by a well-marked diuresis, and often by heavy sweats, so that there might be a loss of weight amounting to as much as 5 or 6 lb. in the 24 hours. With the subsidence of the dropsy the albuminuria usually improved considerably. Hyaline casts were the most abundant, granular next, and epithelial next in order of frequency. A moderate rise of systolic blood pressure was almost invariably present during the period of œdema, falling to a normal level or below it as the œdema subsided. The diastolic pressure was less affected. During the period of raised tension there was frequently a marked difference in the height of the morning and evening pressures, the latter being the higher. In the great majority of cases a very definite hydræmia could be demonstrated. Although cardiac symptoms were frequent, the only physical sign was a temporary enlargement of the heart to the left in 23 per cent. On discharge from hospital, however, the heart appeared to be normal, as judged by the ordinary methods of clinical examination. Chemical investigations showed no differences in kind between this and ordinary nephritis, but merely that it was of a milder type. Usually the chemical results ran parallel with the clinical course. In a few instances, however, the results of chemical investigation were much less grave than the immediate clinical manifestations appeared to indicate. Such cases did well. They found the urea in the blood was usually increased, while the chlorides were variable. In the two cases of fits—which recovered—the urea in the blood was not appreciably raised, whereas in a fatal case of uræmia it was exceedingly high. This is interesting as supporting the conclusion to which this outbreak has gradually been leading various observers, that the various clinical manifestations usually regarded as uræmic are not due to the same toxins, and that the most dramatic of the symptoms, the convulsions, are really the least serious.

The *third* part of the report is a laborious investigation by Captain MacLean into a possible relationship of previously existing albuminuria to war nephritis. The results are entirely negative, no such relationship being found.

The *fourth* part is a bacteriological investigation by Captain J. A. Wilson, also negative in its findings, since routine examination of the urine, blood, throat, and fæces, failed to demonstrate a causal organism.

It will be seen that these reports confirm in the main the earlier observations, such as those made at St. Bartholomew's Hospital in 1915. The chief point of difference is that whereas 30 per cent. of the earlier cases had a positive Wassermann reaction, all of 90 cases here investigated showed a negative result. The chief new point is the relationship of the incidence of the cases to climate, which was entirely lacking in the earlier phases of the outbreak. But the question as to why nephritis has been so frequent in this war and so rare in all previous wars, except the American Civil War, still remains unanswered.

In our last week's issue we published a paper by Captain S. C. Dyke mainly relating to the prognosis of this disease. He found that in 40 per cent. of his series the re-establishment of renal function was incomplete and some degree of permanent damage resulted to the general health. He held the early disappearance of œdema to be one of the best prognostic signs; its persistence after the second week made the outlook worse; while the presence of œdema after the end of the first month indicated that restoration to health would be incomplete. In the same way albuminuria continuing after the end of the third month rendered the prognosis as to complete recovery unfavourable. His suggestion is that the disease is either a primary acute nephritis or an exacerbation of a pre-existing disease induced by fatigue or exposure, and he thinks that an inquiry into the alterations of metabolism produced by fatigue would yield fruitful results. Such an inquiry has been thoroughly undertaken by Captain Macleod, and his conclusions do not support this suggestion. A paper in the *Quarterly Journal of Medicine* for January, 1918, by Captain W. H. Tytler and Captain J. A. Ryle gives as their impression an increasing doubt as to whether the kidney lesion is the primary event—whether, in fact, the nephritis is not a complication of some other disease, possibly pulmonary. That this is probable is indicated not only by the pulmonary lesions in fatal cases but by the enlargement of the spleen, which this last observer found to occur frequently. That the nephritis once thus established should be closely similar to ordinary nephritis would then be comprehensible, since nephritis is so usually the result of an infection or an intoxication. But the effect of such a cause might persist long after the cause had disappeared; hence the negative bacteriological findings. A pulmonary infection might also be expected to show the seasonal variation which the Medical Research Committee have noted.

LONELY DWELLERS AND THEIR NEIGHBOURS.

IT was stated in the newspapers recently that a woman, 73 years of age, living alone in a house in Gray's Inn-road, fell downstairs one Wednesday evening, and, being unable to move, was not discovered until the following Saturday. On the next day she died in the hospital to which she had been taken. Stories of this kind, or of solitary

persons who die and whose bodies are only discovered after some time, are not infrequent, and such cases occur in the country as well as in great cities. Probably, however, they are rarer in rural districts and small towns, where eccentric characters and the poor and lonely are of greater interest to their neighbours than they are in the metropolis. It is difficult, indeed, to suggest any means which would prevent such an occurrence in the crowded area round Holborn, nor can we say that any duty of neighbourliness was neglected by those in her vicinity who went their daily way while an old woman lay at the foot of a staircase in a house which they had no reason for entering. Nor does society, the State, or the local authority appear to be called upon to interfere if persons of mature age, whether poor or not, prefer to live alone rather than in surroundings which would expose them to observation. In the absence of organised intervention it is usually the baker, or the milkman, or the postman, particularly the last in country districts, who reports that he cannot get the accustomed answer at a certain door, when further inquiry shows that a lonely dweller is ill or dead. It might conceivably be made an instruction to postmen to be observant in such matters, and to report the non-delivery of a letter through failure to get a reply to a knock at the door. But lonely dwellers receive few letters. There remain the baker and the milkman, whose services might also be requisitioned in normal times, but even then there are many cases where the customer fetches his own bread or milk from a shop where his abode is not known. It is, indeed, likely that any such system as we have suggested, even if reinforced by the aid of the police, would not only lead to many false alarms, but would break down and be inoperative in a substantial proportion of genuine instances. Cases, therefore, such as that upon which we have commented will continue to fill us with pity, but will not be averted unless and until the State undertakes even greater surveillance over the details of our daily lives than it does at present. Do we want that?

THE SIMULATION OF MUMPS.

AT a recent meeting of the Société Médicale des Hôpitaux of Paris MM. Trémolières and L. Caussade reported a curious form of simulated disease which appears not to have been previously described. A Moroccan soldier was sent back from the front and passed in succession through seven "formations sanitaires" with the double diagnosis of mumps and hysterical crises. Probably in every hospital the first diagnosis was abandoned, but the real nature of the affection was not ascertained. From the moment he first came under the observation of MM. Trémolières and Caussade they were struck by the unusual character and evolution of the parotid swellings. They involved the retro-maxillary hollow, the neck and the pre-auricular, zygomatic, and temporal regions, giving the head a pyriform appearance. On some days the eyelids were affected, so that the features were unrecognisable. The parotid tumours were resistant, difficult to delimit, and little painful. There was no fever. The orifices of Stenson's ducts were projecting and red, and on pressure emitted a remarkably aerated saliva. One day it was noticed that the tumours were resonant on percussion and were accompanied by subcutaneous emphysema. The patient was then submitted to radioscopic examination and the purely aerial nature of the swellings was confirmed. Two days later he was surprised while forcibly blowing out his cheeks, pinching his nostrils, and applying his hand to his mouth. By inflating his parotid glands he had simulated mumps. He had even in his efforts ruptured an acinus, and the air had penetrated into the periglandular cellular tissue. The repetition of the manœuvre had led to a secondary inflammation of the gland, as was shown by the abundance of polynuclear cells in the saliva removed from Stenson's duct by catheterism. It was then ascertained that this method of simulating mumps was well-known among the Moroccan soldiers. They pricked the mucous membrane of the cheek and then blew hard into a bottle or simply closed the mouth with the back of the hand. Being ignorant of the existence of Stenson's duct, they did not know that the prick was useless. This simulation is therefore of the same nature as the parotid swellings which occur in glass-blowers and performers on wind instruments. In the discussion which followed M. E. de Massary pointed out that the simulation of mumps, whether in the parotid or the testicle, can be detected by lumbar puncture. He has found that lymphocytosis of the cerebro-spinal fluid is constant in mumps. The knowledge that such a test might be applied should stop the simulation.

TRAUMA AND IMPOTENCE.

OUR conception of the remoter results of traumatism is constantly being widened by the experiences of the war, but its effects on sexual activity have received little notice in this country. Bloch[1] divides trauma as a cause of impotence into psychical and physical. As to the former, his researches show mental depression by itself can lower sexual potency, which is always impaired in nervous diseases marked by depressive states. It has been observed that men rarely become fathers in the year of their bankruptcy. Anger, too, is antagonistic to sexual activity. The more sudden and acute the mental shock, as from scenes of bloodshed, so much the more obstinate is the impotence. In ancient and mediæval superstition magicians were credited with being able to cast a spell of impotence upon a man through the agency of fright. John Hunter related a case of impotence coming on very rapidly from fright, and the same has followed sudden bereavement of a startling kind. In the front line of a battle it is obvious that all these emotional factors have abundant play. With regard to the pathogeny of impotence thus caused, Bloch doubts whether it is purely psychical; if of long continuance, some unknown disturbance of the internal secretions, of the endocrinic system, is probably responsible. Thus a Dutch clinician recorded amenorrhœa and acromegaly in a woman 25 years old, with no abnormal family history, attributed to severe fright; and an increase of the secretion of the adrenals has been found in the blood after great mental excitement. Physical trauma may be divided into trauma to the genitals or other part of the body generally and trauma to the central nervous system. In war experience sexual paresis is often met with from the pain of an injury. If the genitals themselves have not been greatly injured the prognosis is good, potency usually returning with healing of the wound and cessation of the pain. The outlook is much worse when the cause is concussion of the brain or spinal cord, these cases being similar to the impotence and testicular atrophy long observed in civil practice as an occasional sequela to falls on the back of the head

[1] Iwan Bloch: Zeitschrift für Sexualwissenschaft, July, 1918.

or like injury. The "Scythian disease" of Herodotus and Hippocrates may have had a similar history. But the old view that injury to the cerebellum occasioned the genital disturbance has now been shaken by the work of Ceni, who describes "higher genital centres" in the cortex cerebri which exercise trophic influence upon the reproductive organs, especially upon spermatogenesis and ovulation. Experimentally produced commotio cerebri in animals has been followed by absence of libido and by parenchymatous testicular atrophy. These genital centres are described as much slower to recover from trauma than are the ordinary motor and sensory cerebral centres. Hence the long continuance of impotence following physical trauma to the central nervous system.

SANDFLY FEVER OR INFLUENZA.

IN the *Annali d' Igiene* of June 30th Professor G. Sampietro gives the reasons for the belief prevalent in Italy that the epidemic which began in the second half of last May and was prevalent in Spain and thence spread over Europe is identical with the so-called three-day fever or sandfly fever. The clinical picture of this epidemic may be thus summed up:—

Sudden onset of fever, which as a rule remained high for two or three days, accompanied by severe muscular pains, localised specially in the back and lower limbs, with headache, prostration, anorexia, and coated tongue. In some cases there were signs of pharyngeal and tracheal irritation, which rarely developed into a catarrhal condition; in others there was gastro-intestinal disturbance. Convalescence was attended with marked debility, which lasted from one to two weeks. There was no skin eruption or enlargement of the spleen. The prognosis was favourable. Pfeiffer's bacillus, which is one of the specific agents in influenza, was only exceptionally met with, but, on the other hand, the municipal laboratory at Madrid demonstrated in the secretions the frequent presence of a Gram-negative diplococcus of the type of *Micrococcus catarrhalis*. Clinically the symptoms coincide exactly with those of the disease endemic in Italy and well known among the military population as *pappataci* or sandfly fever, while the late epidemic does not resemble dengue fever owing to the absence of relapses and exanthema, nor trench fever owing to the absence of recurrences and enlargement of the spleen and the leucopenia; nor does it conform to true influenza on account of the want of symptomatic polymorphism, the typical duration, and scarcity of catarrhal elements affecting the respiratory system.

From the epidemiological point of view the diagnosis of sandfly fever derives confirmation from the fact that this fever usually prevails from the middle of May to the end of September, whereas influenza and trench fever are not epidemic in the summer. The epidemic of phlebotomus fever in Lemnos, described by Temporary Surgeon J. Lambert, R.N., in the *Journal of the R.N.M.S.* for April last had this seasonal incidence, the author taking the view that the absence of catarrhal symptoms would readily assure the differential diagnosis from influenza. The phlebotomus or sandfly is a small grey dipterous insect which makes its appearance about the end of May and disappears early in October, thus exhibiting a strange coincidence with the seasonal occurrence of three-day fever. Only the females bite during the night, their flight is inaudible, and they penetrate into bedrooms only when the atmosphere is completely tranquil, and at dawn return to their habitations in dark and damp cellars and deposit their eggs in underground localities where rubbish, wood, and vegetable detritus abound, or in dilapidated walls, gutters, and pipes. It can therefore easily be understood how difficult it is to prove the presence of the phlebotomi in any given epidemic. On the other hand, some account must be taken of the war conditions now prevalent. Everywhere a large quantity of wood, destined to supply material for the construction of defence works, barricades, and huts, has been transported, and doubtless with them also eggs of the phlebotomi, and with this accumulation of material there has been aggregation of human beings in heated barracks or factories to establish conditions favourable to the development of the phlebotomi at altitudes and in localities which might seem to be incompatible with their life. Moreover, the rapid decline of the epidemic after a sudden and rather brief period of climax is more in favour of an infection transmitted by means of insects and related to their natural history than of a disease propagated by contagion.

SOCIAL STUDY AND RESEARCH.

THE death of Sir Ratan Tata at the age of 47 years calls attention to the remarkable development of "social science" which his wise generosity did so much to foster. Mr. Jamsetjee N. Tata, whose industrial prescience in India brought him great wealth, died on the eve of endowing various useful schemes of research. His cloak fell on his two sons. The younger, Sir Ratan Tata, founded the department known by his name in the London School of Economics, and established a fund in 1912 in connexion with London University for promoting the study of the prevention and relief of destitution and poverty. Since this time social study courses have been instituted all over the country: in London, at Bedford College and King's College for Women; elsewhere in connexion with the Universities of Belfast, Birmingham, Bristol, Edinburgh, Glasgow, Leeds, and Liverpool; while courses are in contemplation at the Universities of Manchester, Sheffield, and Wales, and at the Armstrong College, Newcastle. A report,[1] drawn up by the Joint University Council for Social Studies constituted a year ago, describes this new faculty and its present status. Great stress is laid on giving the student a living insight into the various civic and social agencies of a modern town and their mutual action and reaction. There is a very welcome passage in the report which deprecates the teaching of the facts of social life without a preliminary grasp by the student of the facts of physical life. It is quite possible, the passage runs, those most interested in social education have belonged too exclusively to the school of thought which consider social well-being in relation to moral and economic health rather than to physical health. The just claim of hygiene for inclusion as an essential part of social science is now gaining ground, with promise of much greater results in the future. The Parsee community, with the Tata family at its head, has played an honourable rôle in making these results possible, and Sir Dorab Tata, the elder son of Mr. Jamsetjee Tata, is certain to follow in his father's footsteps.

Dr. Addison, Minister of Reconstruction, will speak at a meeting of the medical profession to be held at Steinway Hall on Oct. 1st, at 5.30, under the chairmanship of Sir Henry Morris. The object of the meeting is to secure the election of representative medical men to the House of Commons, so that expert advice may be available on vital questions concerning the national health. All members of the medical profession are invited to attend.

NATURAL SCIENCE IN EDUCATION.

NOTES ON THE REPORT OF THE COMMITTEE ON THE POSITION OF NATURAL SCIENCE IN THE EDUCATIONAL SYSTEM OF GREAT BRITAIN.

BY ERNEST H. STARLING, F.R.S.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY COLLEGE, LONDON.

THE astounding and disastrous ignorance of the most elementary scientific facts displayed by members of the Government and administration alike in the early days of the war roused some doubts in the minds of the British public as to the efficiency of the education imparted at a high price to the members of the upper classes, including those who are chiefly responsible for the control of the destinies of this country. The Government adopted the traditional method of poulticing the sore place in public opinion by the appointment of two committees, one on the position of natural science in our educational system and the other on the teaching of modern languages. It is with the report of the first of these committees that we are here concerned. The Committee was under the presidency of Sir J. J. Thomson, P.R.S., and included representatives of secondary, university, professional, and technical education. The Committee was appointed in August, 1916, and the report before us is a testimony of the diligence with which the members executed their task. The Committee sat on 45 days and subcommittees on another 51 days; the report itself is dated February, 1918, and naturally a large amount of work was done by members of the board apart from meetings in committee.

Defects in Present System.

It should be noted that the title of the report is "The Position of Natural Science in Education,"[1] and the report contains a series of recommendations, which, if carried into effect, must result in a greater importance being ascribed to the natural sciences in the educational curriculum, especially in that of the general public; so that some of the blunders perpetrated through the ignorance of our rulers may possibly be avoided in the future. But ignorance of elementary chemical facts forms but a small factor in the gross deficiencies of our educational system. It is impossible to read this report without feeling that all its recommendations, even if realised, might do little for the growth of the nation if we cannot achieve at the same time a revolution in the whole aim and system of education. It is not sufficient merely to introduce natural science into the school curriculum. In many schools, in the majority in fact, it is already there. What are lacking are scientific aim and method, and the recognition by the public at large and by every class of the community of the meaning of knowledge and of science and of the part which science must play in every action taken, whether by the individual or the State. It is the absence of science and scientific method, not ignorance of chemistry, which has been responsible for our failures of leadership in the conduct of the war, whether at home or on the Western front.

In this connexion the volume of essays[2] just issued under the editorship of Professor Ray Lankester might well serve as an introduction to the report of the Committee on Natural Science. The best and most illuminating of these essays were written as long ago as 1867, at a time when there was a short period during which the British public stirred in its sleep, under the influence of the shaking up of its fundamental ideas effected by the publication of the theory of evolution, and the theological discussions aroused thereby. For the first time since the founding of the Royal Society, moreover, a royal personage had taken an active interest in the development of science in this country. Huxley's essays and addresses on education, like the essays in the collection before us, are applicable in every particular to the present day, and the question arises whether the public, under the influence of the severe lesson it has received during this war, will repent of its former sloth and apathy and, acting upon the recommendations here made, will endeavour to fit itself for the strenuous struggle for existence which will continue for many decades after the war.

It is apparent that the main defect in our present education is not so much the time that is spent on the study of Latin or Greek, but the fact that so many years are passed at school and nothing is learnt. After nine years nine-tenths of the boys can read neither Latin nor Greek. They may have acquired a few catchwords or allusions to classical mythology, but they can give no account of the manner in which the Greeks lived, of the part played by Greek philosophy or art in the evolution of modern ideas, or of the way in which Western government has been founded on Roman inventions. Though their studies have been almost entirely literary and grammatical, they are incapable of writing or speaking with ease or fluency any language, including their own. And not only have they learnt nothing which will serve as intellectual guidance in their future life, but they have had their enthusiasm for new knowledge damped and their curiosity destroyed.

Aim of Education.

If we are to make our education scientific the first requisite is to decide what we are aiming at, and then to elaborate the means by which our aims may be attained. Natural science will then fall of itself into its proper place. It can hardly be denied that the aim of education is to fit the boy for his future work and position as a member of the community. The rise of animals in the scale of life has been determined by the evolution of an educatable part of the brain, the cerebral cortex, so that the animal can control and alter the inherited mechanical responses of the lower parts of the central nervous system in accordance with the teachings of its own experience. Even in the lower animals this automatic education by individual experience is reinforced by the example and training of the parent animal, and in man the intervention of speech has rendered it possible to guide the reactions of the growing animal by the accumulated experience not merely of the parents but of the rest of the civilised world.

It is the office of education, therefore, to prepare the young for their future work by placing at their disposal such a summary and collection of the total human experience as are essential for making them efficient members of the community. All this would seem self-evident; but it does not represent the guiding principle in our education, nor is it often thought of in our public school system, although parents will make considerable sacrifices in order that they may send their boys to public schools. Nothing can be more foolish than to assume that all men are fools. Men send their sons to public schools because there are some advantages which more than outweigh under present conditions the disadvantages of a senseless method of education. It has often been stated that a boy goes to a public school because he receives there the education of a gentleman. It may be objected that this is mere snobbery, but, at any rate, if, as Frenchmen allege, "*le snobisme*" is the ruling principle of our organisation, it must be to the benefit of the newcomer into the organisation to conform to its principles.

For, however the fact may be camouflaged in leading articles and election addresses, feudalism is ingrained deeply in our constitution. The ruling classes have resisted destruction of the system by the tactful absorption of newcomers and possible rivals, so that town and country alike are still scattered with baronial castles, where the inmates, fortified by possession of birth or capital, take toll of the community. And those who cannot enter into this class have devised a method for the avoidance of over-much exploitation—namely, by the formation of guilds and associations for mutual protection and benefit. In this country, therefore, it is of the highest advantage for his worldly success that a man belong either to the ruling class, as member or retainer, or to a guild of some sort or other; and this is much more important and has a bigger influence on the welfare of the individual than any sort of education he may receive. If the boy is expected to make a career and to obtain posts (apart from the limited number which are offered as a result of a competitive examination in the dry bones of his school curriculum) his success will depend more on what he is or to what guild he belongs than on his intellectual equipment.

It is, indeed, regarded almost as a heresy to demand of a Minister special knowledge of the work which he

[2] "Natural Science and the Classical System in Education: Essays, New and Old," edited by Sir Ray Lankester, K.C.B., F.R.S. Heinemann.

is appointed to direct, and the idea of promotion by merit in the Army or other public services arouses a feeling of horror in the majority of those belonging to these services. And before the war the system seemed to work, at any rate to those who conformed to it, just as a bed of fossils may endure for thousands of years, till it is broken up by a convulsion of nature or ground up by man to make mortar. But a system in which the leaders of the community possess neither the intelligence nor the knowledge to lead must be disastrous in a time of change and stress such as that with which we are faced, and shall be faced for many years to come. The question before the nation is whether we can now finally destroy the remains of the fossil system which impedes and frustrates our best efforts in order to regenerate a living working organism, coördinated and adapted to playing its part in the struggle for survival.

The foundation stone in any such reconstruction is our educational system. If the war is successful in educating the public into the meaning of education, into the value of knowledge (and this we shall not know until our men return from the war), the nation will be ready to accept the suggestions for improvement made in this report and to use them as a means to social and national regeneration.

The Value of the Study of English.

I have mentioned above that once we have rationalised our educational aims natural science will fall into its proper place. But this place is not first in the educational hierarchy. It is universally accepted that the "three R's"—reading, writing, and arithmetic—must form the groundwork of elementary education. We do not recognise in this country that training in language and expression is a necessary precedent and accompaniment of all other education, and that we need a training in the use of our own language not inferior to that given in French in the schools of our Allies. Without appreciation of language clearness of thought is impossible, and literary form is one of the best guarantees of good reasoning. But no training in mere language is sufficient or profitable unless the mind is supplied with material to work upon. A proper training in language as the expression and symbol of things, the relations of things, the relations of men, and finally of the feelings of men, while promoting accuracy of thought and judgment, will minimise the hypnotic influence exercised on the inarticulate by meaningless catchwords and party cries.

The very fullness and perfection of the English language make it, perhaps, the most difficult to master, even by those who are English by birth and upbringing. Most of us have felt how the defect in our school training in English, or its absolute default, continually impedes the expression of our ideas, and prevents any rise out of the ruts of the commonplace. Even a scientific article could and should be beautiful in its fitness of expression, and it will not lose in its usefulness if it pleases the ear as well as satisfies the reason. The majority of our generation have not advanced in the writing of English beyond the stage which, under any proper system of education, ought to be attained by an intelligent boy of 14. But if by this age the boy had learnt not only to express himself with form and propriety, but had also studied the structure and origin of his language and the meaning of the roots, especially Latin and Greek, of the words which he uses, he could begin at 14 the study of Latin as something already half familiar to him, and in a couple of years could attain such a knowledge of this language as is at present reached only by a small minority after six or eight years of stupefying drudgery. Better still if, as Mr. W. Johnson advised in Sir Ray Lankester's volume of essays, he had learnt French with his English. Each language would teach appreciation of and help in the study of the other, and the boy would be ready to play some part in the inter-Allied activities which will replace, we hope, for the next hundred years the present reign of destruction, terror, and pain.

The value of the study of English is strongly emphasised in the Committee's report, which also points out the advantage from a practical standpoint of a knowledge of modern languages. But the report is chiefly and properly concerned, not with the reform of education as a whole, but with the changes necessary to give to the study of the natural sciences its proper importance in the general scheme of instruction. Some of the changes advocated we may now proceed to discuss.

Education in the Schools.

The bulk of the intellectual workers of the country, those who will represent the mass of public opinion, are educated in the secondary schools, and it is to the instruction carried out in these schools that the Committee devotes the greater part of its attention. The report considers in the first place the present conditions of science teaching in the secondary schools. These schools may be divided into (*a*) public schools with about 25,000 boys, (*b*) grant-earning schools with about 103,000 pupils, and (*c*) preparatory and private schools, whose name is legion, but in whose case it is impossible to give any estimate of the number of children educated. The community has, in fact, no evidence either of the number taught or of the quality of the education given, nor has it at present any means of ensuring a standard of teaching in these schools.

So far as concerns the grant-earning secondary schools, the Committee was convinced by the evidence laid before it that science occupies a position in no way inferior to any other subject in the school curriculum. The chief drawback to the training given in these schools is the absence of any power of enforcing a continuous and adequate school course. A large number of boys leave before 15 in order to take up wage-earning work, and such boys have, therefore, had the advantage of only a fraction of a course. Even in the case of those boys who stay till 16, the course in science is unsatisfactory in that it is influenced by the requirements of the university entrance scholarships, which will be competed for by a very small fraction of the total number of the boys undergoing instruction at the school. The course is only the initial stages of a plan which is never completed; the boys learn some facts in isolated chapters of science, but they have no opportunity of obtaining a general acquaintance with science.

On the other hand, in the so-called public schools, which include the 76 schools in England and Wales represented on the Headmasters Conference, the Committee find that "while the majority offer adequate opportunities for the study of science to those boys whose parents desire it, there is as a whole no general recognition of the principle that science should form an essential part of secondary education." And the evil is enhanced by the fact that a number of the brighter boys, who enter a school with a classical scholarship, altogether miss any instruction in science, this instruction on the classical side being confined to the lower forms. The establishment of modern sides has furnished an excuse for, and so augmented the neglect of science on the classical side. In this way it is especially those boys who are destined to take high positions in the public services who enter on their career without having at any time studied the rudiments of science.

The tendency of the abler boys at the public schools to pursue a classical course is due, not to any enthusiasm on the part of the boys for classical studies, but to the scholarship system, which determines their whole career. At the preparatory schools they are crammed for entrance scholarships at the public schools, and the more valuable of them are purely classical, science playing no part. Entering a public school with a good knowledge of classics, but of nought else, the next stage is the attainment of a classical scholarship at Oxford or Cambridge. As might be expected, the classical scholarship winners at the universities are largely drawn from those who have already won scholarships at the public schools. Thus, during the three years ending July 31st, 1914, the total number of classical scholarships gained from the seven chief public schools was 117, while the total number gained for science from the same schools was only 19, of which 6 were gained from one school. Of the 117 classical scholarships 85 per cent. were won by boys who had been awarded entrance scholarships on the foundations of these schools. The Committee concludes—

> "That so far there has been no general and sufficient recognition of science as an essential part of the curriculum for all boys in the public schools; that the effect of scholarship examinations both at the schools themselves and at the universities, and the inequality in the number and value of the scholarships awarded for different subjects, tell against such recognition; and that many of the ablest boys who enter the public schools pass on to the universities ignorant of science and with little or no idea of its importance as a factor in the progress of civilisation or of its influence on human thought."

Recommendations of the Committee.

In order to remedy these defects the Committee emphasises the necessity of altering the character of the existing entrance examinations both at the schools and at the colleges of Oxford and Cambridge, so as to get rid of the excessive specialisation by which the work in all subjects is marred, and of insisting that each candidate for scholarships at universities should take a second subject, so that, if presenting himself for a science scholarship, he should take history, a language, or mathematics, or, if a literary subject, he should give evidence of some knowledge of science. "It is also necessary," the report states, "that the aims and character of a modern education should be more clearly defined not only in schools, but also at universities." Such a definition of aims and character must be gleaned in the report from the scheme it lays down for primary and secondary education.

"The best preparation for any occupation or profession is a general education up to the stage reached by the average boy at the age of 16, followed, where possible, between the ages of 16 and 18 by a more specialised course on a limited range of subjects. This general education should provide normally the study of English, including history and geography, languages other than English, mathematics, and natural science. Each of these subjects should be regarded as an integral part in the instruction of both boys and girls, and a fair balance should be maintained between the time allowed to them."

The effect of the establishment of such a course would be the abolition of the division into sides now usual in the larger schools.

The efficiency of the education now carried out should be determined by making compulsory a periodical inspection under the direction of the State. This recommendation is one of the most important contained in the report. Even though it might be impossible for the State or education authorities to close a school where the education was inefficient or bad, the publication of the results of the inspection would infallibly lead, as has been shown by the experience of the Carnegie trustees in America, to the rapid disappearance of the inefficiency in private schools, which is one of the worst features in our present school system. It would also bring the force of public opinion to bear upon the antiquated curriculum still preserved in some of the so-called public schools, at the present time firmly entrenched behind their barriers of tradition and social prestige.

The general course in science from 12 to 16 should not only train the mind of the student to reason about things which he has observed for himself and develop his powers of weighing and interpreting evidence, but it should also make him acquainted with the broad outline of great scientific principles, with the way in which these principles are exemplified in familiar phenomena, and with their application to the service of man. The Committee is of opinion that the second of these functions of the scientific course has been hitherto unduly neglected; but there can be no doubt of its importance to the boy who is not going to take up a scientific career, but to whom it is essential that he should know what science means and its bearings upon the problems of everyday life. It is not necessary that our administrators or our business men should be scientific men in the ordinary acceptation of the term or that they should be acquainted with a number of facts in physics and chemistry. It is essential, however, that they should recognise that science, as the ordered summary of the whole of human experience, presents the means for solving any and every problem with which they may be faced, and that the method used in attacking scientific problems—the clear vision of the object in view, and the collection and evaluation of all data appertaining to these problems—is the only method which can lead to success in war, commerce, or industry. If the business man appreciates the meaning and capabilities of science he can always find or buy the necessary expert knowledge. In this way the nation as a whole may be brought to recognise the fundamental importance of the facts and principles of science to the right ordering of our national life. So long as our traders or manufacturers are ignorant of the veriest elements of science they can neither state their needs with definiteness or accuracy, nor can they interpret into practice or utilise the results of research.

While we must provide the requisite training and opportunities for those who are capable of advancing natural science or acting as scientific experts, it is no less important that we should secure for all who are of an age to receive it an education which will enable them to realise the vital need of a knowledge of science both for the individual and national well-being. For those boys who remain at school up to 18—and the Committee is adverse to prolonging the school period beyond this age—it is recommended that the greater part of the time between 16 and 18 should be devoted to the study of a group of subjects depending on the boy's tastes and on the career which he intends to follow. It is pointed out that the imaginative and original faculties at this period could be best trained by the intensive study of a few subjects. It is suggested that a boy should devote not more than two-thirds of the school week to work in his special subjects, the other third being spent in some other kind of study—e.g., a science student might occupy this time in English or literary subjects, while the student of classics or modern languages should give his attention to science work of an appropriate kind. For the latter class of boys the science course, so far as possible, should deal with scientific questions of general interest and should be philosophic in the best sense of the term—i.e., a study of the development of scientific thought as it has affected and affects human thought and activities.

Examinations.

University scholarship examinations are not the only factors which trammel the progressive teacher and prevent freedom of experiment and of educational development in the secondary schools. A large proportion of the pupils who stay at school until the age of 16 intend to go to the university or to take up some profession the entrance to which is an examination. Thus every school in arranging its course of study has to take into account the possibility of its students presenting themselves for a number of different examinations: Oxford and Cambridge school examinations; junior and senior locals; previous examinations; responsions; matriculation; Army entrance examinations, &c. The Science Committee proposes that all these shall be virtually abolished by the institution in each school of two school examinations, a junior and senior, the passage of which in the course of time shall admit to any university or profession. It would be obviously impossible to effect such a substitution forcibly, unless by Act of Parliament, since it would interfere with vested interests, the Englishman's Ark of the Covenant. The first school examination should take place at the completion of the general course of study, and should test the results of the instruction in English subjects, languages, mathematics, and science. It should be suitable for average pupils about the age of 16. The Committee lays stress on the importance in this examination of the closest possible coöperation between teachers and examiners. Not only should the examination be adapted to the curriculum of the particular school, but great weight should be attached to the teacher's estimate of the pupils and to their school record. It should thus be carried out in accordance with the view that examinations must be determined by curricula, not curricula by examinations. At the present time it would be for the universities to determine under what conditions they would accept the first school certificate in lieu of their own entrance examination. But it is apparent that, in all cases where a State grant is given to the university, it should be possible to prevent unreasonable conditions being made in order to save a source of income to the university in the shape of matriculation examination fees.

The second school examination would be held at the end of the more specialised course of study between 16 and 18, and it is suggested that the regulations for this examination should be framed so as to be consistent with the scheme for widening the college entrance examinations of which mention has been made above. If this second school examination is satisfactorily conducted it is to be hoped that it might be used in the place of the Intermediate examinations for the Pass Degree held at many of the universities. Students could then proceed to a university ready to undertake at once a three years' course of work for their final degree, and their work during the last two years of school would not be disturbed by having to prepare for an examination, such as the University Intermediate, not primarily designed to meet school needs.

Teachers.

The Committee recognises that the first and indispensable condition to any real improvement in the teaching of science is to ensure an adequate supply of properly trained teachers.

At present teachers are deficient both in number and quality, and we cannot expect to attract the fine type of man to whom should be entrusted the most important of all functions in our society—namely, the training of the coming generation, unless we make the teachers' profession equal in social position and material reward to the other learned professions. The Committee points out that simply to add 10 per cent. or 20 per cent. to present salaries is useless. It is not merely an improvement in the salaries that is needed, but a revolution in the attitude of the public towards the teacher. The times and conditions of his teaching should also be altered, so that he may have leisure to keep abreast with the progress of knowledge, to retain freshness of mind and outlook, and not sink into the condition of a drudge who teaches so-called chemistry and physics as if they were the Latin declensions.

If this improvement can be carried out it is evident that much more real knowledge and training can be obtained in the school years than has hitherto been the case, and the Committee therefore recommends that the upper limit of age for entrance scholarship be 13 in the case of the public schools and 18 in the case of the universities, thus cutting off from the average school life one year, which can be better spent in a more thorough training in the subjects of university study, and especially in the methods and spirit of research.

Medical Education.

In a review of this report published recently in *Science Progress* Dr. C. Mercier has spoken of it as diffident. The same epithet might be applied to nine-tenths of the reports issued by Government committees and commissions. To the English mind and habit anything savouring of revolution, at any rate with subjects with which it is familiar, is distasteful. Even the report before us only ventures to use the word "revolution" in connexion with the salaries of teachers, finance not being a matter which or linarily concerns members of the Committee. In all their recommendations relative to the methods of education the reforms advocated, though in the right direction, are generally of the mildest description. This criticism applies with special force to the recommendations contained in the section on medical education. In this connexion the report adheres directly to the terms of its reference, and does not apparently regard anatomy and physiology, still less the science of medicine itself, as coming under the definition of natural science. It is thus concerned only with the question of entrance to the medical profession and the preliminary scientific education of the medical student.

The report strongly criticises the failure of the General Medical Council to demand evidence of instruction in or knowledge of natural science at the entrance examination, trust being placed solely in an examination which demands four subjects—English, mathematics, Latin, and an additional language, classical or modern. It points out that not only is there no guarantee that the candidate for registration has received any instruction in natural science, the bedrock of his future vocation, but there is no evidence that he has gone through a coherent educational course in any of the subjects demanded. Attention is called to the illogical procedure of the General Medical Council in professing not to register a student unless he takes Latin as one of his subjects, while accepting for registration the matriculation examination of various universities, although Latin is not a compulsory subject in any of them. The report points out that after the door has already been opened in this way it is too late to attempt to retain Latin as an obligatory subject in an examination for entrance to the medical profession. The Committee is strongly of opinion that the first school examination, including English, language, mathematics, and natural science, should be accepted as evidence of a general education sufficient to admit a student to professional instruction. It is suggested that something more than a simple pass should be required—e.g., it should be necessary to attain marks of distinction in two or more of the subjects in which he is examined at his school. In cases where boys and girls, by accident, laziness, or ill-development, have failed to reach an adequate standard in the first examination, it is suggested that they might be admitted as medical students if they continue at school and pass the second examination as well. The report favours the present policy of the Royal Colleges by which every encouragement is given to the study of the preliminary sciences, chemistry, physics, and biology, at school. It is evident that such a policy is entirely in accord with the plan already discussed of spending the years from 16 to 18 at school in specialised studies having reference to the future career of the boy or girl. In the case of students proceeding to medicine these studies would be scientific; but the report lays stress on the disadvantage of separating future medical students from the rest of the school in classes by themselves. It is an elementary but complete course in chemistry, physics, and biology which is needed by the medical student at the outset of his career and as a preliminary to the more intensive study of biological principles as contained in the discipline of anatomy, physiology, and biochemistry.

The Committee recommends that the student be allowed to present himself for the first medical examination immediately on leaving school and before entering the medical school or university, but does not take the further step of advocating the entire replacement of the first medical examination by the second school examination, though such a development is distinctly favoured in the section dealing with education in the Scotch universities. It is evident that unless this change can be effected the school curriculum in science from 16 to 18 will be spoiled by having its direction and objects determined by the needs of the external examination. In all three subjects—physics, chemistry, and biology—the present medical school and university course might be replaced by a complete two years' course at school on the same subjects, with considerable benefit to the later work of the student. Especially is this the case in biology. A training in general biological principles, developed in any direction according to the ideas and enthusiasm of the teacher at school, would be of value to the medical student. The present course in many cases is of little more value than the training in Latin grammar which does duty so often for an introduction to the study of language.

The report touches on the future supply of medical students, and insists that, in view of the shortage in the supply of medical men and the heavy expense of the medical curriculum, it is essential that more scholarships, tenable throughout the medical course, should be provided for candidates of both sexes.

University Education.

Some of the more important of the recommendations with regard to the universities have already been touched upon. Others, apart from the recommendation that compulsory Greek should be abolished at Oxford and Cambridge, relate to research and to scholarships. The high value of research, carried out under the guidance of the teacher, as an educational weapon is set out, and it is stated as desirable that a year spent mainly on research should form part of the work of university students preparing for careers concerned with science and its applications. This period spent on research should follow the course for a first degree in science. It is laid down that scholarships should be considered as distinctions, and should therefore be in the first place of merely nominal value, to be supplemented according to need, and that, where necessary, the whole cost of a scholar's education and maintenance should be thus defrayed. In a footnote to the section dealing with University Scholarships an estimate by the consultative committee as to the annual cost of education and maintenance at the university is quoted. This at Oxford and Cambridge is put at £140, and at the newer universities at £60 together with the sum required for fees. If the present cost of living remains after the war it seems likely that these estimates will have to be doubled if the holders of the scholarships are not to suffer from starvation.

The Committee remarks that the war has not only hampered their inquiry but must sadly retard the realisation of their hopes. This is surely a somewhat pessimistic attitude. If the war has done nothing else it has shown us that in matters of urgent necessity it is unprofitable to count the cost. How many millions have been spent on our new tactical weapon, tanks? Forty millions a year is given as a subsidy to keep down the price of bread. An expenditure of money equal to that devoted at the present time to the provision of gas masks for the Army would cover all the needs of education for many years to come. If only the conviction can be brought home to the nation of the urgent need of educational reform, or even revolution, for the maintenance of our place in the world, all that are required on the part of our administrators are a clear idea of the reforms necessary and courage to carry them out.

THE MEDICINAL USE OF LARD, OLIVE OIL, AND CASTOR OIL.

MEASURES have now been taken to meet as far as possible the shortage of lard, olive oil, and castor oil, methods having been devised for their discontinuance for medicinal purposes in certain circumstances. The Committee appointed by the Home Office in August, 1914,[1] to deal with questions of economy in the use of drugs during the war are now notifying the medical profession as to the supply, for medicinal purposes, of these substances, and certain similar vegetable oils, inviting their coöperation in effecting economies while submitting the pertinent suggestions which appear below. The prior claims of food-supply and munition production have for some months compelled restriction or even discontinuance of the use of the substances above named for medicinal purposes, the present position being that (1) *lard* is no longer released for medicinal use; (2) the amount that can be set free for such use of *olive oil* and of its possible substitutes, *sesame* and *arachis* oils, is uncertain; and (3) little, if any, of the quality of *castor* oil hitherto required for conformity with the Pharmacopœial standard can be used.

To obviate the resulting difficulties the General Medical Council, after consultation with the Home Office Committee, directed the alteration and amendment of the British Pharmacopœia, 1914, certain preparations being withdrawn from the Pharmacopœia until further notice, and sanctioned the use of various substitutes (see THE LANCET, April 13th, 1918, p. 543). By these alterations of the Pharmacopœia considerable latitude was accorded in the dispensing of prescriptions that contained the official preparations affected. That definite understanding on this point should be established between prescribers and dispensers the Pharmaceutical Society, acting in coöperation with a body of representative manufacturers and in consultation with the Home Office Committee, undertook the necessary experiments, and have constructed a set of war emergency formulæ which are published by the Society. (Codex Addendum, 1918.)

The following suggestions are offered by the Home Office Committee for the assistance of practitioners in prescribing, in view of the position as above described:—

Lard.

(*a*) Lard can no longer be dispensed either as such or as an ingredient of a prescription. A base consisting of 5 per cent. wool fat, 10 per cent. hard paraffin, and 85 per cent. soft paraffin is on the market, and will, it is believed, afford a suitable substitute for most cases in which lard would previously have been ordered. For some cases the practitioner may find it advisable to modify the proportions of the ingredients named. (*b*) Ointments containing lard or lard and suet are now allowed to be prepared with wool fat or paraffin or mixtures of these in place of the lard or lard and suet, which may no longer be used. The base described above (named for convenience adeps factitius) has been found to afford a satisfactory substitute in the preparation of these ointments, and war emergency formulæ containing it have been constructed. Practitioners will assist by ordering these formulæ except in special cases in which they think it advisable to modify the composition of the base.

Olive Oil.

(*a*) For olive oil sesame oil or arachis oil may be substituted, but none of these vegetable oils should be ordered avoidably. When required *for external purposes* a specially prepared mineral oil derived from petroleum (known as paraffinum liquidum flavum) is now obtainable, and will in most cases be found to afford a satisfactory substitute. (*b*) Four liniments containing olive oil have ceased to be official. War emergency formulæ containing the specially prepared mineral oil above mentioned have been devised. Liniments so prepared are on the market, and may be substituted for the former official preparations.

Castor Oil.

(*a*) For castor oil it has been found, as the result of investigations by the Medical Research Committee, that the neutralised seconds castor oil, now recognised by the Pharmacopœia and readily obtainable, affords a satisfactory substitute for the first quality oil hitherto used. (*b*) One preparation containing castor oil has been withdrawn—viz., liq. cresol saponatus. For the preparations containing castor oil remaining official—i.e., collodium flexile, lin. sinapis, and liq. epispasticus, the neutralised seconds oil will be used by the manufacturer or chemist in place of the oil previously official.

The suggestions of the Home Office Committee will be very welcome to medical practitioners. The Codex Addendum was fully dealt with in our columns last week (THE LANCET, Sept. 7th, p. 336).

[1] The present members of the Committee are as follows: Dr. J. Smith Whitaker (chairman); Sir Thomas Barlow, formerly President of the Royal College of Physicians of London, consulting physician, University College Hospital; Dr. A. Cox, medical secretary of the British Medical Association; Dr. E. Rowland Fothergill; Dr. B. A. Richmond, secretary of the London Panel Committee; Dr. F. J. Smith, physician, London Hospital; Dr. W. Hale White, physician, Guy's Hospital; secretary, Dr. E. W. Adams, medical officer of the National Health Insurance Commission, late lecturer in pharmacology, University of Sheffield.

URBAN VITAL STATISTICS.

(Week ended August 31st, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality was 11·2, against 10·4 and 10·8 per 1000 in the two preceding weeks. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 10·5, or 0·9 per 1000 above that recorded in the previous week; among the remaining towns the rates ranged from 4·0 in Swindon, 4·3 in Southport, and 4·4 in Bath, to 18·8 in Gateshead, 21·8 in Barnsley, and 26·1 in West Hartlepool. The principal epidemic diseases caused 541 deaths, which corresponded to an annual rate of 1·7 per 1000, and included 435 from infantile diarrhœa, 33 from whooping-cough, 27 from measles, 26 from diphtheria, 12 from scarlet fever, and 8 from enteric fever. The deaths from diarrhœa, which had steadily increased from 34 to 305 in the seven preceding weeks, further rose to 435, and were 123 in excess of the number registered in the corresponding week of last year; 71 deaths were recorded in London, 45 in Birmingham, 29 in Liverpool, and 21 in West Ham. The 701 cases of scarlet fever and 888 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 9 below and 7 above the respective numbers remaining at the end of the previous week. Of the total deaths in the 96 towns 123 resulted from violence. The causes of 41 deaths were uncertified, of which 6 were registered in Birmingham, 5 in Leicester, and 3 each in London and Liverpool.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 9·4, against rates declining from 17·4 to 9·9 per 1000 in the six preceding weeks. The 196 deaths in Glasgow corresponded to an annual rate of 9·2 per 1000, and included 18 from infantile diarrhœa, 5 from whooping-cough, and 1 each from enteric fever, measles, and diphtheria. The 59 deaths in Edinburgh were also equal to a rate of 9·2 per 1000, and included 3 from infantile diarrhœa and a fatal case each of scarlet fever and diphtheria.

Irish Towns.—The 130 deaths in Dublin corresponded to an annual rate of 17·0, or 1·6 per 1000 below that recorded in the previous week, and included 24 from infantile diarrhœa and 2 from whooping-cough. The 96 deaths in Belfast were equal to a rate of 12·7 per 1000, and included 7 from infantile diarrhœa and a fatal case each of measles and diphtheria.

(Week ended Sept. 7th, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality was 11·9, against 10·8 and 11·2 per 1000 in the two preceding weeks. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 11·4, or 0·9 per 1000 above that recorded in the previous week; among the remaining towns the rates ranged from 1·0 in Oxford, 4·1 in Aberdare, and 4·4 in Bournemouth, to 19·5 in Sunderland, 20·0 in Dudley, and 23·0 in South Shields. The principal epidemic diseases caused 543 deaths, which corresponded to an annual rate of 1·7 per 1000, and included 431 from infantile diarrhœa, 45 from whooping-cough, 37 from diphtheria, 16 from measles, and 7 each from enteric fever and scarlet fever. The deaths from diarrhœa, which had steadily increased from 34 to 435 in the eight preceding weeks, slightly fell to 431, but were 101 in excess of the number registered in the corresponding week of last year; 91 deaths were recorded in London, 41 in Birmingham, 40 in Liverpool, 17 in Sheffield, 14 in West Ham, and 12 in Hull. Diphtheria caused a death-rate of 2·3 in Bootle and 3·5 in St. Helens. The 748 cases of scarlet fever and 875 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 47 above and 13 below the respective numbers remaining at the end of the previous week. Of the total deaths in the 96 towns 114 resulted from violence. The causes of 32 deaths were uncertified, of which 6 were registered in Liverpool, 5 in Birmingham, and 3 each in London and South Shields.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 10·9, against 9·9 and 9·4 per 1000 in the two preceding weeks. The 249 deaths in Glasgow corresponded to an annual rate of 11·7 per 1000, and included 16 from infantile diarrhœa, 7 each from whooping-cough and diphtheria, and 4 from measles. The 63 deaths in Edinburgh were equal to a rate of 9·9 per 1000, and included 2 each from whooping-cough and diphtheria and 1 from infantile diarrhœa.

Irish Towns.—The 132 deaths in Dublin corresponded to an annual rate of 17·3, or 0·3 per 1000 above that recorded in the previous week, and included 23 from infantile diarrhœa, 3 from enteric fever, and 1 each from measles, scarlet fever, whooping-cough, and diphtheria. The 85 deaths in Belfast were equal to a rate of 11·3 per 1000, and included 10 from infantile diarrhœa and 3 from enteric fever.

DEATH OF DR. P. W. WILKINSON.—Percy William Wilkinson, M.B., C.M. Edin., died recently at his residence at Bere Alston, Devon, in his fiftieth year. The deceased was the eldest son of the late Rev. W. Wilkinson, rector of Week St. Mary, Devon. Dr. Wilkinson had been in practice at Bere Alston for many years and was highly respected.

Correspondence.

"Audi alteram partem."

NASO-PHARYNGEAL INFECTION AT THE ONSET OF CEREBRO-SPINAL FEVER.

To the Editor of THE LANCET.

SIR,—Major J. Dorgan, in his letter to THE LANCET of August 17th, disputing Lieutenant-Colonel M. H. Gordon's statement that "every case of cerebro-spinal fever was in reality an instance of a carrier developing the disease" makes three definite points—namely:—

1. In 41 cases of declared cerebro-spinal fever at X only 19 had meningococci in the throat. In 4 cases in London only 1 had meningococci in the throat.
2. Nine men swabbed a short time before they developed cerebro-spinal fever failed to show evidence of meningococci in the throat.
3. 520 carriers were isolated at X and none developed cerebro-spinal fever.

From these results he concludes that Colonel Gordon's statement is incorrect.

Colonel Gordon in his reply deals with point 1 by stating that negative results are of less value than positive, and "success requires special training, experience, and sometimes considerable perseverance as well." Captain Martin Flack always took two swabs. It may, however, be pointed out that these cases were examined by Professor Samut and by Captain Armstrong, of the Central C.S.F. Laboratory. The London cases were examined by Captain J. A. Glover and two were swabbed twice. That is to say, all of the cases were examined in what one might describe as Colonel Gordon's own laboratory.

Not content with this sort of criticism, he then proceeds to suggest that "a considerable proportion" of the cases in which these workers failed to find meningococci in the throat were really not cases of cerebro-spinal fever at all. Although they found Gram-negative intracellular diplococci in the cerebro-spinal fluid and isolated them in half the cases and finally agglutinated them with specific serum, he doubts the diagnosis and suggests that these cocci are "a few sterilised diplococci" introduced into the fluid from the skin of the patient's back. This is an extremely far-fetched suggestion. His position is obviously untenable when we are told that the cocci were actually grown and identified by the Professor of Bacteriology at Malta University. He could surely tell the difference between the living meningococcus and the dead staphylococcus albus.

The points 2 and 3, made by Major Dorgan, are very relevant to the discussion, but are avoided by Lieutenant-Colonel Gordon.

I may point out that Temporary Surgeon S. L. Baker and I in the Navy established precisely similar points to those indicated by Major Dorgan, with whose work we were totally unacquainted. We came to the same obvious conclusion—namely, that Colonel Gordon's statement was much too sweeping, in fact, incorrect. Our work is quite well known to Colonel Gordon. If he still wishes to maintain the accuracy of his statement, or if he wishes to convey the impression that he still maintains it, he will find his audience unsympathetic if he can bring no better argument than this.—I am, Sir, yours faithfully,

P. FILDES,
Hon. Staff-Surgeon, R.N.V.R.

R.N. Hospital, Haslar, August 17th, 1918.

A NASAL DRILL IN THE TREATMENT OF ADENOIDS.

To the Editor of THE LANCET.

SIR,—The new therapeutical departure, referred to in Dr. Isabel Ormiston's paper and in your editorial annotation of August 24th, which we owe to Mrs. E. Handcock's acumen and single-minded endeavours, is of wider significance than might appear at first sight. The beneficial action of her harmless powder and of her advocacy of a physiologically efficient use of the handkerchief for "nose-pumping" rather than nose-wiping is sufficiently demonstrated by the success of her happy thought of treating in batches the snuffling children who crowd our out-patient rooms. Naso-pharyngeal sanitation, upon which so much depends, is in the first place a mechanical proceeding, best carried out by fully utilising the viscidity of the mucus for the purpose of drawing it out from the depth in an unbroken stringy stream. Nose-blowing, as it is usually taught in the nursery, interrupts its discharge. That recommendation applies *a fortiori* to adults with more capacious mucous recesses, as those can testify who have obtained complete relief of their catarrhal troubles from her simple methods, without any need for antiseptic inhalations or irrigations as a second resort. The chief significance of this new departure is in its underlying principle: *functional treatment* for the cure of malfunction and for the timely prevention of its structural results at an early age, as well as of its reflex consequences at all ages, although by far the most formidable reflex complications belong to the spasmophilic period of early childhood. The structural results are a thickened mucous membrane, adenoid overgrowth, and tonsillar hypertrophy. The last of these, in the absence of that functional treatment, too often imposes upon us the most unphysiological of remedies, a mutilation of our perfect organism. The avoidance of tonsillectomy has been for years Mrs. Handcock's steady and confident aim. In that connexion I have availed myself of her valuable aid in one instance, and with most satisfactory results, in a little boy liable to frequent gastric upsets culminating in alarming attacks of pyrexia and tachypnœa suggestive of acute pneumonia or broncho-pneumonia. The threatened tonsillectomy has not been required, and for upwards of a year he has enjoyed perfect health, and has rapidly made up for the previous delay in his development and strength.

I am, Sir, yours faithfully,

Upper Brook-street, W., August 27th, 1918. WILLIAM EWART.

To the Editor of THE LANCET.

SIR,—I am glad to find that the non-operative treatment of adenoid growths as practised by Mrs. E. Handcock is being recognised by the medical profession. I have had many opportunities of seeing cases under her care, and the following notes may be deserving of record.

E. H., age 12. Had a severe fright when 2½ years of age, after which she complained of severe pain in both eyes and constant headaches; was treated in several hospitals for partial blindness, and was eventually told she would become quite blind. I saw her in the summer and autumn of 1913, when she first came under Mrs. Handcock's care, and she was then unable to see even large objects without the aid of glasses. There was nasal obstruction and adenoid vegetations, no discharge, breath offensive, and she complained of a nasty taste in the mouth; appetite poor, and she was anæmic. There was considerable thickening over the bridge of the nose, and also behind both ears. She was dull, stupid, and apathetic, walked badly, had night terrors, and slept very badly. The skin was harsh and dry, and she had never perspired. Feet, hands, and abdomen were always cold.

After a few weeks' treatment there was free discharge from the nose, slightly offensive, the thickening over the nose and behind the ears had almost disappeared, she could read large print without glasses, the appetite was good, she slept well, and had no night terrors. The skin was soft and smooth, and she perspired after active exercise. About six months later she looked a bright, intelligent, and normally healthy girl, and had grown considerably.

This case is a good illustration of what can be done by a skilfully applied treatment, and shows that the use of glasses in cases of defective eyesight is not always necessary. The use of the nasal powder should not, I think, come first in the matter of treatment, but should rather be considered as an adjunct to the drill and manipulations.

I am, Sir, yours faithfully,

Sept. 4th, 1918. WALTER C. BLAKER, M.R.C.S., &c.

THE TREATMENT OF WAR NEUROSES.

To the Editor of THE LANCET.

SIR,—In response to my suggestion that it would be of value if Major A. F. Hurst and Captain J. L. M. Symns could give the late, as well as the immediate, results of their treatment they state that, "from all we have been able to hear the number of relapses is exceedingly small" and "we do not know of a single man invalided from our neurological centre who has relapsed." I can only attribute this to their not having had the time or opportunity to follow up many of their discharged cases, for I have seen relapsed and uncured cases from every neurological centre in Great Britain, including Netley.

I do not suppose that your correspondents would claim that their results are better than those obtained at other centres; at any rate, my experience of several hundreds of such uncured pensioners leads me to the conclusion that all the

neurological centres get equally good early results as to the removal of symptoms, but that relapses after discharge are unfortunately very common. Anyone anxious to investigate the point will find thousands of these relapsed and uncured cases, many of them totally disabled, if he will make inquiries at the Special Medical Board, the Y.M.C.A. Special Exchange, or at the various Local War Pensions Committees.

Relapse most commonly occurs after a man has been discharged from hospital where he was under complete medical control, when he has to resume the freedom, cares, and responsibilities of ordinary life. Such a man may still figure in the hospital records as "cured," though he may, in fact, be as incapable as he was to start with, and unfortunately in a condition now confirmed and much less likely to be cured a second time by suggestion. I hold that it is as unreasonable to claim soon after the symptoms have disappeared that neurotic conditions are "cured" as it would be for a surgeon immediately to record as "cured" all the malignant growths he has partially or wholly excised.

With regard to the country host scheme, common sense suggested that neurasthenia (nervous debility or exhaustion) would be, as in years past, removed by good country food, fresh air, and reasonably guided rest and exercise. All who have to deal with these cases will, I feel sure, be glad to hear that experience confirms this view, and, that the results of the scheme are encouraging, is definitely attested by the fact that the Ministry of Pensions has just decided to extend the scheme to all areas of the United Kingdom. At the neurological centres, including Seale Hayne, excellent and indeed indispensable work is being done, but I am convinced that a "half-way house" of diminished control, such as the country host scheme provides, is a necessity if relapses are to be prevented.

I am, Sir, yours faithfully,

Sept. 7th, 1918. THOMAS LUMSDEN.

*** We understand that the scheme of the Country Host Institution, in addition to its extended use by the Ministry of Pensions, has now been accepted by the Navy for undischarged sailors. The Institution finds suitable work for the men on their return from the country.—ED. L.

WAR DEAFNESS.

To the Editor of THE LANCET.

SIR,—Dr. P. McBride asks (THE LANCET, August 24th, p. 253) for a concrete example of functional deafness—a condition which he considers to be rare—and I submit the following :—

Pte. J. R. was blown up and partially buried by a shell on Feb. 15th, 1918. He became totally deaf at once and did not lose his speech nor show other hysterical signs. There was a discharge from both ears for four weeks after the explosion. Specialists found bone conduction lost and concluded that "the site of the deafness is the labyrinth on each side." He was admitted to the Seale Hayne Military Hospital on Sept. 4th, 1918, and the following day was treated for 30 minutes by pure suggestion, with the result that he heard perfectly normally after seven months of total deafness.

Now, if on account of the discharge from the ears and the bone deafness this case had not been regarded as hysterical for fear of doing him a "very grave injustice" he would undoubtedly have been invalided from the Army totally deaf and probably would have remained so. Injustice would lie rather in not regarding all cases of concussion deafness as at least partially functional from the first.

I am, Sir, yours faithfully,

J. W. MOORE.
Captain, M.R.C., U.S.A.

Seale Hayne Military Hospital, Newton Abbot, Devon, Sept. 8th, 1918.

ANTIMONY IN BILHARZIOSIS.

To the Editor of THE LANCET.

SIR,—I can fully confirm Dr. J. B. Christopherson's results given in his paper in your issue of Sept. 7th. I began to use antimony in bilharziosis in 1912 ("Biology and Treatment of Venereal Diseases," p. 349), and have treated 23 cases with a disappearance of ova in the urine. I do not know how many cases relapsed, but one case I treated with bitartrate-potassium-ammonium-antimony oxide (antiluetin) in 1914 is well to-day. I have used three preparations: (1) tartar emetic intravenously in doses of 1–1½ gr., dissolved in 5 oz. of water, to avoid thrombosis, twice or three times a week; (2) antiluetin intramuscularly and intravenously alternately, beginning with 0·025 g. and ending up with 0·2 g.; (3) colloidal antimony, both intravenously and intramuscularly, in doses of 0·5 c.cm. to 2·0 c.cm. of a 0·2 per cent. emulsion. Alternate intramuscular and intravenous injections have given better results than using only one route. Both antiluetin and colloidal antimony appear to be more efficacious than tartar emetic. Colloidal antimony is the least toxic, but as far as can be judged not quite so potent in its action as antiluetin, but possibly much larger doses might be well stood. No preparation of arsenic in my hands has done any good, but the use of intramine (a sulphur compound) both increases the action of the metal and inhibits its toxic effect. On the precise way in which antimony works in bilharziosis (other than as an oxidising agent) I can throw no light; I only used it empirically in view of the good results obtained in other diseases caused by animal parasites, which remain uninfluenced by salvarsan. I am at present precluded from further investigating the use of antimony in bilharziosis, but hope that others will discover the best antimony compound to use.

I am, Sir, yours faithfully,

Wimpole-street, W., Sept. 9th, 1918. J. E. R. MCDONAGH.

CONGENITAL PYLORIC STENOSIS.

To the Editor of THE LANCET.

SIR,—In regard to the case report of congenital pyloric stenosis reported in your issue of June 8th, in which Dr. T. Jason Wood performed a gastro-enterostomy with a very successful result, it might be pointed out that a gastro-enterostomy is a rather severe procedure in these half-starved infants and that pylorectomy, which he presents as an alternative operation, is never indicated. Statistics show that the best results have been obtained by the "Webber operation." In this procedure the pyloric tumour is split longitudinally throughout its whole length into the muscularis mucosæ; when this layer is reached the cut edges of the tumour are drawn apart forcibly and the underlying mucosa bulges into the incision. The patency of the pylorus can then be demonstrated by expressing gas through the stomach into the duodenum. On the antero-superior surface of the tumour there is an almost avascular area and if the incision is placed in this situation little bleeding is encountered. When the constriction has been relieved in this manner nothing further is done and the abdomen is closed.

Some operators prefer to undermine the serosa on either side of the incision in the tumour and bring it over the gap in the muscular wall; this, however, does not seem to be necessary, as nature covers the base of the incision with peritoneum in a very short time. It is not uncommon to find that the distal end of the tumour almost forms an invagination into the duodenum, and in splitting the tumour the proximal part of the duodenal mucosa may be nicked by the scalpel, allowing the escape of duodenal contents. This has occurred in several of our cases, but the opening has been closed very easily by a fine chromic gut suture, perhaps reinforced by a small omental graft; no ill-effects have followed. This operation is simple, short, and meets all requirements. The post-operative shock is reduced to a minimum. The first case in the Hospital for Sick Children, Toronto, done by this method some four years ago is now apparently a normal, healthy child.

Immediately following this operation it is our routine to perform a transfusion of whole blood on the infant from either parent. This procedure gives the patient a physiological stimulus that cannot be obtained by any other means. The blood transfusion is a most valuable adjunct in treatment and, undoubtedly, has helped materially to save some desperate cases. The transfusion is done by the syringe method, giving at a maximum not more than 15 c.cm. of blood per pound of body weight of the recipient. This usually means an amount of from 75 to 100 c.cm. of blood. The difficulty of finding a suitable vein in an infant is largely obviated by using the saphenous vein over the internal malleolus, which can be felt if it cannot be seen.

In a report from the Hospital for Sick Children, Toronto,[1] by Dr. W. E. Gallie and myself, 18 cases were cited with 5 deaths. Further cases to the number of 15 have been done by this method, with 4 deaths.

I am, Sir, yours faithfully,

L. BRUCE ROBERTSON,
Major, C.A.M.C.

Toronto, Canada, August 8th, 1918.

[1] Journal of Canadian Medical Association, June, 1917.

The War.

THE CASUALTY LIST.

THE following medical officers appear among the casualties announced since our last issue :—

Killed.

Capt. W. M. Lansdale, R.A.M.C., attached Royal Berks Regiment, was a student at Guy's Hospital, London, and qualified in 1914, just after the outbreak of war. He joined up shortly afterwards.
Lieut.-Col. H. H. Moshier, Canadian A.M.C., qualified at the University of Toronto in 1909, and was professor of physiology at the University of Alberta at the time he came over with the Canadian Expeditionary Force.
Capt. W. Rogerson, R.A.M.C., attd. Royal Berks Regiment.
Capt. A. Morton, R.A.M.C., attd. Highland Light Infantry.

Died.

Capt. E. W. Waters, East African Medical Service.

Died of Wounds.

Capt. R. B. Taylor, M.C., R.A.M.C.

Wounded.

Lieut. W. M. Heald, R.A.M.C., attached Lancs Fusiliers.
Capt. G. Kirkhope, R.A.M.C., attached Dragoon Guards.
Capt. A. H. Wallace, Canadian A.M.C.
Capt. D. J. Evans, R.A.M.C., attached Tank Corps.
Capt. W. D. Newland, R.A.M.C.
Major M. A. Power, M.C., R.A.M.C.
Capt. J. R. John, R.A.M.C., attached Sherwood Foresters.
Capt. D. F. Riddell, R.A.M.C., attached Cheshire Regiment.
Capt. A. K. Forbes, R.A.M.C., attached Coldstream Guards.
Lieut. W. P. Nelson, R.A.M.C., attached London Regiment.
Capt. L. H. H. Boys, R.A.M.C., attd. Royal Warwick Regt.
Lieut. T. Davies, R.A.M.C., attached Dorset Regiment.
Major W. Murdoch, M.C., R.A.M.C.
Major J. McL. Pinkerton, M.C., R.A.M.C.
Capt. E. C. A. Smith, R.A.M.C., attached Lancs Fusiliers.
Major G. H. R. Gibson, D.S.O., Canadian A.M.C.
Capt. H. G. Young, D.S.O., Canadian A.M.C.

Previously reported Missing, now reported Prisoners in German Hands.

Capt. C. C. Jones, R.A.M.C.
Capt. F. H. McCaughey, R.A.M.C., attd. North'd Fusiliers.
Capt. W. A. Rees, R.A.M.C.

THE HONOURS LIST.

The following awards to medical officers are announced :—

K.C.V.O.—Maj.-Gen. W. G. A. Bedford, C.B., C.M.G., A.M.S.
C.M.G.—Lt.-Col. P. W. O'Gorman, I.M.S.; Lt.-Col. R. T. Brown, D.S.O., R.A.M.C.
To be Brevet Major.—Capt. (temp. Maj.) W. E. Marshall, M.C., R.A.M.C.
D.S.O.—Maj. W. McConaghy, R.A.M.C.; Maj. R. S. Kennedy, M.C., I.M.S.; Temp. Lt.-Col. A. G. P. Gipps, R.A.M.C.; Maj. R. B. Purves, R.A.M.C.
Military Cross.—Temp. Capt. P. L. T. Bennett, R.A.M.C.; Temp. Capt. H. W. Hodgson, R.A.M.C.

BROUGHT TO NOTICE.

The names of the following medical officers have been brought to the notice of the Secretary of State for War for valuable services rendered in connexion with the sinking or damage by enemy action of hospital ships, transports, and store ships. All are members of the R.A.M.C. :—

Lt.-Col. H. S. Anderson, C.M.G.; Temp. Capt. P. L. T. Bennett; Temp. Capt. T. L. Butler; Maj. W. S. Crosthwait; Temp. Capt. E. G. Fenton; Temp. Lt.-Col. A. G. P. Gipps; Temp. Capt. J. H. Glover; Temp. Capt. P. Gully; Temp. Capt. H. W. Hodgson; Temp. Maj. W. E. Home; Temp. Capt. H. E. Moore; Temp. Capt. (acting Lt.-Col.) W. Penberthy; Maj. J. H. E. Priestley, C.M.G.; Maj. R. B. Purves, attached Yeomanry; Temp. Capt. J. L. Rentoul; Temp Capt. J. Robertson; Temp. Maj. G. S. Samuelson; Temp. Capt. R. A. Shekleton; Temp. Capt. H. Slater; Temp. Lt. R. H. Thomson; Temp. Capt. T. Tierney; Capt. C. E. W. Wilmot.

MENTIONED IN DESPATCHES.

In a despatch received from the Commander-in-Chief of the Mesopotamia Expeditionary Force, dated April 15th, 1918, the following reference to the medical service occurs :—

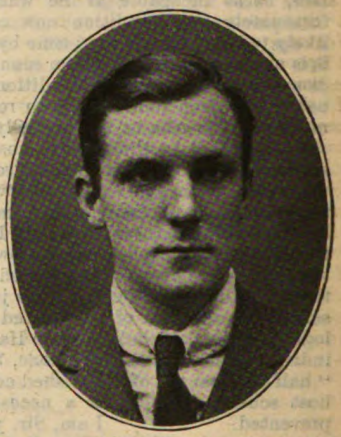
The high standard of efficiency displayed by all ranks of the Medical Service has been most gratifying to me, and reflects great credit on Surgeon-General A. P. Blenkinsop, C.B., C.M.G., my Director of Medical Services. The health of the troops has shown marked improvement as compared with the corresponding months of 1916-17. The sanitary organisation and administration has steadily progressed, and the standard of comfort and efficiency of the hospitals is most satisfactory.

OBITUARY OF THE WAR.

DOUGLAS TAYLOR, M.B., CH.B. GLASG.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant D. Taylor, who died on active service on July 26th, at the age of 23 years, was only son of the late John Taylor, M.D., of Whiteinch, Glasgow. He was educated at Glasgow High School, entering Glasgow University in 1912 and graduating M.B., Ch.B. five years later after a successful academic career. During his final year of study he acted as clinical assistant at Govan District Asylum, Hawkhead. On graduating the state of his health at first prevented him from joining the R.A.M.C., and he accepted an appointment for several months as medical officer in the district of Torridon, Ross-shire. On receiving his commission later he was sent to the Near East last June, and while engaged in work at a base hospital he contracted dysentery and malaria, from which he died in hospital at Salonika. Described as a student by nature and of a kind and sympathetic disposition, Lieutenant Taylor had given promise of filling an honourable place in the medical profession.



GEORGE HELY-HUTCHINSON ALMOND, M.A., M.B. OXON.

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain G. H.-H. Almond, who was killed in action on August 9th, at the age of 41 years, was only surviving son of the late Hely-Hutchinson Almond, sometime headmaster of Loretto. He was educated at Edinburgh Academy, Loretto, and Oxford, where he took honours in science in 1902, going on to St. Bartholomew's Hospital, London, for his clinical studies and qualifying M.B., B.Ch. Oxon., in 1908. He held a number of resident hospital appointments in London before settling in practice at Bath, where he became honorary pathologist to the Royal Mineral Water Hospital and assistant pathologist to the Royal United Hospital. He had as a student served in the Yeomanry during the South African War, and in 1915 he received a commission in the R.A.M.C., going out as a pathologist. Captain Almond's careful work as a pathologist was well known to his fellow-workers. One of his colleagues at Bath writes of his "infinite capacity for taking pains," and his published work in the *Bristol Medico-Chirurgical Journal* and our own columns testifies to this faculty. A study which he made of the joint fluids in arthritis awaits publication. The equipment of the Bath laboratories owes much to his enthusiasm. His chief at a London Hospital writes to us at length of his personal qualities. "He loved his work; he was skilful and careful; he was unfailingly gentle and courteous to his patients; he worked well and

happily with everybody." Both correspondents speak of Captain Almond's forgetfulness of self and self-interest, which made his life tell on other men's lives. Captain Almond was married to a niece of the late Sir William MacCormac, and leaves a widow and three sons.

LIONEL ARTHUR MARTIN, M.R.C.S. ENG.,
SURGEON, ROYAL NAVY.

Surgeon L. A. Martin, who was accidentally killed at sea at the age of 31 years, was youngest son of Edward F. Martin, M.D., of Weston-super-Mare. He was educated at St. Peter's School, Weston-super-Mare, and at Epsom College, where he was a keen member of the O.T.C. Commencing his medical studies at University College, London, in 1905, he took the qualification of the Conjoint Board in 1912, and was about to take the Final M.B. Lond. when war broke out. He at once resigned his appointment as house physician at University College Hospital to join the Navy, and was appointed surgeon to H.M.S. *Vindictive* in August, 1914, serving with her to July, 1916, when he was appointed to H.M.S. *China*. His death occurred suddenly in the pursuance of his duties through an accident to one of the ship's boats.

Surgeon Martin's senior M.O. writes of his value as an organiser in working the sick bay staff and looking after the general administration of the hospital. His untiring energy and perserverance were always at the disposal of his seniors, and his loss will be hard to fill.

DAMER HARRISSON, F.R.C.S. EDIN., M.CH. (HON. CAUSÂ) LIVERP.,
COLONEL, A.M.S.

Colonel Harrisson, whose death we recorded last week, joined the surgical staff of the David Lewis Northern Hospital of Liverpool in 1882 and retired in 1913, returning to active work again when war broke out. He had risen to the position of surgeon lieutenant-colonel in the Lancashire Hussars, and was recently administrative medical officer of the West Lancashire Territorial Division. As a recognition of his services in this capacity he was made honorary surgeon to the King. He had held a number of teaching and other appointments; he was university lecturer on clinical surgery and medical officer to the special schools for defective children. His published work was on the surgery of the brain and nervous system.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Major A. R. Carter, R.G.A., attached R.A.F., died of wounds, third and youngest son of Dr. G. Carter, of Sheffield.

Second Lieut. J. Y. P. Jones, Welsh Regiment, killed in action, only son of Dr. J. Jones, of Clydach, Swansea Valley.

Capt. J. A. Summerhayes, Labour Corps, attached Inniskilling Fusiliers, killed in action, eldest son of Lieut.-Col. J. O. Summerhayes, D.S.O., R.A.M.C. (T.F.), of Thame, Oxon.

Capt. W. M. Lansdale, R.A.M.C., killed in action, son of Dr. W. Lansdale, of Grove Park, Lee, London.

Second Lieut. E. J. Mortis, Royal Guernsey Light Infantry, reported missing, now reported killed in action, younger son of Dr. H. E. Mortis, of Kinnerley, Oswestry.

Lieut. T. F. H. Torney, killed in action, only son of Captain H. Torney, R.A.M.C., of Cowbridge, South Wales.

Capt. B. C. Hall, Manchester Regiment, killed in action, only surviving child of Dr. H. Strange Hall, of Leigh, Lancs, medical officer of the Leigh Auxiliary Medical Hospital.

Obituary.

ROBERT SAUNDBY, M.D. EDIN., F.R.C.P., LL.D. (HON CAUSÂ) MCGILL AND ST. AND., M.SC. BIRM.,
EMERITUS PROFESSOR OF MEDICINE, BIRMINGHAM UNIVERSITY; LIEUTENANT-COLONEL, R.A.M.C.(T.)

THE death of Dr. Robert Saundby on August 28th of heart trouble, from which he had long suffered, removes a man of dominant personality, who had for long been a leader of the medical profession in the Midland counties.

Robert Saundby was born in London on Dec. 9th, 1849, and began his career as a tea-planter in the East until obliged by ill-health to return to England. On his voyage home the suasion of a medical fellow-passenger turned his thoughts in the direction of medicine, with the result that he entered Edinburgh University, taking the degrees of M.B., C.M. in 1874, and of M.D. three years later. After qualifying, he was for a time resident physician to the Royal Infirmary at Edinburgh, and house physician to the City Chest Hospital in London before his appointment in 1876 as pathologist to Birmingham General Hospital, which began his association with the city where he spent the 40 years of his active professional life. In the following year he was appointed assistant physician, becoming full physician in 1884, and only relinquishing office in 1912 to become consulting physician. His first teaching appointment was that of lecturer on comparative anatomy at the Queen's College, Birmingham, which he relinquished to become professor of medicine at the Mason University College, merged later in the University of Birmingham. He was in succession Bradshaw, Middlemore, and Ingleby Lecturer, and last year delivered the Harveian Oration at the Royal College of Physicians of London. He was president of the Birmingham Medical Institute, and a vice-president of the British Medical Association, and for 12 years the representative of Birmingham University on the General Medical Council.

It was to his public work that Saundby gave the greater part of his time, and the broader interests of hospital and university prevented him from acquiring a consulting practice commensurate with his ability. He was extraordinarily scrupulous in the performance of his hospital duties, spending many hours each week in the wards, where his wide knowledge of medical literature and his close familiarity with current French work made his teaching of special interest. He never neglected the less interesting cases; but in any discussion on the history of a disease or method of practice he would often reveal an astonishing acquaintance with out-of-the-way facts. He had a sound knowledge of pathology, and was a constant attendant at post-mortem examinations, while his judicial mind, unswerving in the pursuit of truth, fitted him well for original research when he had time to undertake it. His writings, without being highly original, are in the nature of well-digested presentation of fact, amplified by personal experience.

In his relation to students Saundby set a very high standard as examiner, making the M.B., Ch.B. Birmingham a degree hard to obtain, and therefore the more valued. To the less painstaking or less conscientious student his searching questions in ward or examination hall were something of an ordeal. Saundby tolerated no slipshod answer, no looseness of thought, no slovenly case-taking. But as intimacy grew the student's fear changed to affection, and Saundby commanded in a very high degree the respect of his colleagues. He was not an easy man to oppose, and was naturally impatient of stupidity or ignorance, with a hot temper which did not suffer fools gladly. In consequence his actions sometimes made him unpopular, but no one ever accused him of seeking his own, and time often proved him right and his actions to have been in the best interest of his profession. His code of medical ethics, embodied in a series of lectures which were re-published, was a noteworthy contribution to medical practice.

His earliest published work dealt with diabetes and Bright's disease, in which he always maintained his interest. He was one of the founders of the *Midland Medical Journal* and its editor in early days. He translated Ewald's "Diseases of the Stomach" for the Sydenham Society and was himself one of the first to give immediate feeding to cases of gastric ulcer. With his colleague, Gilbert Barling, he paid much attention to the surgical treatment of gastric diseases, and was specially helpful to patients in laying down

sound dietetic lines and general advice upon their mode of life. His clinical perspicacity pointed out the identity of ulcerative colitis with sporadic dysentery, while unusual cases of disease rarely escaped him, a description of the first recognised case of acromegaly in England being from his pen. His last work, on "Old Age," reveals ripe judgment and experience. As he became older his mind remained fresh and receptive, enabling him to deal fairly with the work of younger men and to find its appropriate niche for each new fact.

The passing of Saundby leaves behind the memory of a strong and unselfish man whose life was spent for the good of his profession and the enhancement of its influence on the life of the nation. A staunch friend, a foe to injustice and deceit, a man retiring by nature but whose sense of duty obliged him to overcome his shrinking from publicity—these are the traits by which he will be held in honoured remembrance.

Dr. J. W. Russell writes:—

"Dr. Saundby was a man of strong personality. His clinical work was essentially scientific. His reading was wide, and he had an extensive knowledge of contemporary research; this he applied in the wards of the hospital and in his private practice. He was keen to test for himself any new method of investigation or treatment, judged it carefully and critically, and rejected or retained it according to the result. To work under him was to learn thoroughness of investigation and the application of strict methods of thought. Above all, he set a fine example of loyalty and devotion to his hospital work. During many years of his active service he rarely missed a daily visit, and the least interesting of his cases had from him all that he was able to give.

Dr. Saundby was a keen critic. His mental grasp was clear and rapid, and he saw at once the weak points of an argument, as well as the right course to take in any difficult public matter. For this reason he was looked to in many ways as the leader of the profession in Birmingham, and as a guide in matters of medical policy, whilst his advice was frequently sought in private difficulties. During the formation of the University he played an important part in laying down the policy of the medical faculty, and he brought great dignity to the chair of Medicine. He was hardly a great teacher: he learned so easily himself that he failed to some extent to understand the difficulties of the ordinary man. But those who followed his work, and especially his house physicians, learned great lessons from him, and many of his younger colleagues have cause to remember with gratitude the encouragement and help given them in their early years.

His personal character was exceedingly fine. The quickness and certainty of his mental processes made it at times difficult to put up with opposition and dissent, and a certain irritability of temperament gave rise to occasional misunderstandings. But those who knew him best realised how little all this really meant, and of what warmth of affection and loyalty of friendship he was capable. The outstanding point in his character was a great uprightness and honesty, and the single-mindedness with which he pursued his ideals. These were high, both in public and private matters, and they were never lowered to suit his convenience. He never tolerated what he thought wrong, and took his own straight course entirely regardless of, and often in direct opposition to, his own interests. In Dr. Saundby the profession has lost a strong and sincere man and a real leader."

Dr. Saundby married in 1880 Mary Edith Spencer, of Wolverhampton, and leaves a daughter and two sons. A third son was killed last year in the Royal Flying Corps.

WILLIAM REID, M.D. ABERD.

Dr. William Reid, superintendent for more than 25 years of the Aberdeen Royal Asylum, died at Lochhead on Sept. 3rd. The son of the late Rev. William Reid, minister of Auchindoir, he had a distinguished career at Aberdeen University along with his two brothers, Robert W. Reid, now Regius professor of anatomy in the University, and the late Major-General Sir A. J. F. Reid. Graduating in 1876, he almost at once became junior assistant to Dr. Jamieson, who was then medical head of the asylum, and succeeded him on his death 15 years later. During his term of office he saw the great institution reconstructed at a cost of £50,000, with the addition of a branch asylum at Daviot. The success of this vast undertaking owed much to Dr. Reid's able administration. He was responsible for the introduction of female nursing on both sides of the asylum, a measure which, at the time, was severely criticised. Dr. Reid was also lecturer on mental diseases at the University of Aberdeen. Socially, he entered with zest into the corporate life of the University. Dr. Reid was married to a daughter of William Bruce, of Dingwall, who with two daughters survives him.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointment has been notified: Temp. Surg. N. MacLeod to *Africa*.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Probnrs. C. C. Mackinnon (temp.) to *Crusader* and M. W. Kemp to *Swift*.

To be Surgeon Probationer (temp.): S. A. Gunter.

ARMY MEDICAL SERVICE.

Temp. Col. T. Sinclair, C.B., relinquishes his commission, and is granted the honorary rank of Colonel.

Temp. Major A. W. Robertson, R.A.M.C., to be a temporary Deputy Assistant Director-General.

Capt. and Bt. Major (acting Lieut.-Col.) C. H. S. Frankau, D.S.O., to be temporary Colonel whilst specially employed.

The undermentioned temporary Lieutenant-Colonels to be temporary Colonels: H. Wade, D.S.O. (Captain, R.A.M.C., T.F.), C. C. Choyce, R. Davies-Colley.

ROYAL ARMY MEDICAL CORPS.

E. H. Paddison relinquishes his commission and is granted the honorary rank of Captain.

Temp. Lieut. C. L. Forde to be temporary Captain.

J. R. H. Walker, late temporary Captain, is granted the honorary rank of Captain.

Temp. Hon. Lieut. S. H. Kagan to be temporary honorary Captain.

Temp. Lieut. G. F. Hunter relinquishes his commission on account of ill-health contracted on active service, and is granted the honorary rank of Lieutenant.

E. Miskin, late temporary Lieutenant, is granted the honorary rank of Lieutenant.

R. P. Mitchell to be temporary Honorary Lieutenant whilst serving with the British Red Cross Society in France.

The undermentioned Majors relinquish the acting rank of Lieutenant-Colonel on re-posting: J. M. H. Conway, D.S.O., W. F. Ellis.

The undermentioned to be acting Lieutenant-Colonels:—Whilst specially employed: Temp. Major H. F. Woolfenden, Capt. M. P. Leahy. Whilst in command of a Medical Unit: Temp. Capt. (acting Major) J. G. Johnston, Major T. S. Coates, O.B.E., Major W. F. Ellis, Major (Bt. Lieut.-Col.) G. Ormrod.

The undermentioned temporary Captains relinquish the acting rank of Major on re-posting: J. M. Forsyth, H. Gooaman, V. L. Connolly, J. H. Porter.

Temp. Major H. H. Serpell relinquishes the acting rank of Lieutenant-Colonel on re-posting.

The undermentioned temporary Captains relinquish their commissions and are granted the honorary rank of Captain: C. S. Bowker (on account of ill-health), C. Townshend (on account of ill-health contracted on active service).

The undermentioned temporary Captains to be acting Majors: W. G. Johnston, M.C., H. Goodman, J. W. C. Gunn, G. W. Smith, M. N. Perrin, E. S. Sowerby, J. H. Porter, E. L. Puddicombe (whilst specially employed).

F. H. Scrimgeour to be a local Major and to be granted the pay and allowances of a Major whilst specially employed.

The undermentioned Lieutenants (temporary Captains) to be Captains: F. J. Hallinan, T. J. L. Thompson, S. Robertson, J. H. Baird, W. D. Anderton, W. L. E. Reynolds, A. G. P. Hardwick, H. A. Rowell, (acting Major) W. K. Campbell, D.S.O., (acting Major) O. B. Pratt, J. H. Boag, C. G. G. Keane, C. R. Dudgeon, (acting Major) H. E. A. Boldero, R. C. Matson, H. R. Sheppard, (acting Major) W. T. Hare.

The undermentioned to be temporary Captains: Temp. Lieut. E. G. Pringle, H. Devine (whilst specially employed).

Temp. Lieut. A. V. Moberly relinquishes his commission on account of ill-health.

Temp. Lieut. H. J. Brewer relinquishes his commission on account of ill-health, and is granted the honorary rank of Lieutenant.

The undermentioned Lieutenants to be Captains: H. N. Pritchett, W. J. Walters, G. F. Mitchell, G. K. Fulton, W. Adams, R. Aitken, T. Fleming, J. S. Martin, N. Mackillop, W. Dempster, E. P. Irving, J. H. Shearer, W. McWilliam, J. Ashforth, J. S. Craig, H. E. Charles, C. H. Smith, P. Shillito, N. Pick, G. F. Hurst, H. V. Horsfall, J. H. Parker, S. Adler, P. V. Anderson, H. J. Rice, J. M. Savage, J. B. Kirk, D. McEachran, J. C. Burns, S. L. Smith, J. O. P. Smith, L. Walker, J. McI. H. Smellie, R. Mailer, W. A. Weatherhead, C. B. B. Reid, J. S. Bow, D. W. McLean, R. Andrew, J. H. R. Smith, B. W. Jones, R. J. L. Fraser, A. B. Austin, P. F. A. Grant, A. B. McA. Lang, F. W. Sandeman, D. S. Mitchell.

The undermentioned to be Lieutenants: T. H. Almond, from Manchester University Contingent, O.T.C.; A. E. B. Paul, from University of London Contingent, O.T.C.

SPECIAL RESERVE OF OFFICERS.

Capt. W. F. McLean to be acting Lieutenant-Colonel whilst in command of a Medical Unit.

Capt. F. R. H. Mollan to be acting Major.

Capt. C. H. Thomas relinquishes his commission on account of ill-health, and is granted the honorary rank of Captain.

The undermentioned to be Lieutenants:—Second Lieut. E. J. S. Bonnett, from Unattached List, T.F., and F. R. G. Heif. From University of London Contingent, O.T.C.: T. Patterson, S. A. Withers, and W. A. Flynn. From Edinburgh University Contingent, O.T.C.: C. Simpson and D. C. Lamont.

TERRITORIAL FORCE.

Capt. E. D. Macnamara relinquishes his commission on account of ill-health, and is granted the honorary rank of Major.

The undermentioned Lieutenants to be Captains: B. M. Brander, R. C. Davie, C. M. Smith.

Capt. A. H. Falkner to be Major.

The undermentioned Captains to be acting Majors whilst specially employed: J. A. Davies, P. R. Bolus.

Capts. P. N. Cave and V. A. P. Costobadie relinquish their commission on account of ill-health and are granted the honorary rank of Captain.

Lieut. (temp. Capt.) W. Gilliatt and J. H. Ryffel to be Captains.

Lieut. C. W. Yates to be Captain.

The announcement regarding Capt. (temp. Major) J. Hamilton which appeared in THE LANCET of August 3rd is cancelled.

Major W. Broadbent is seconded for service overseas.

Capt. F. J. Wethered is retired under para. 116, T.F. Regulations, and is granted the honorary rank of Captain.

ROYAL AIR FORCE.

Medical Branch.—The undermentioned are granted temporary commissions as Captains: W. G. Helsby, A. Bradford, J. N. Macdonald (late Captain, R.A.M.C.). T. M. Davies is granted a temporary commission as Lieutenant.

Medical Branch (Administrative).—H. J. Beale is granted a temporary commission as Second Lieutenant.

Dental Branch.—A. Williams is granted a temporary commission as Lieutenant.

OVERSEA FORCES.

Canada.

Temp. Majors W. G. Turner and A. L. Johnson to be acting Lieutenant-Colonels whilst specially employed.

Temp. Capt. W. L. Mann to be acting Major whilst specially employed.

Temp. Major G. S. Mothersill, D.S.O., to be temporary Lieutenant-Colonel.

Temp. Major W. A. G. Bauld to be acting Lieutenant-Colonel.

Temp. Capts. W. J. E. Mingie and F. E. Pettman to be temporary Majors.

Temp. Capt. J. Seager to be acting Major.

The undermentioned temporary Lieutenants to be temporary Captains: F. H. Nelson and E. N. Ballantyne.

South Africa.

Temp. Capt. C. F. Beyers relinquishes his commission.

INDIAN MEDICAL SERVICE.

To be temporary Colonel while holding an appointment as A.D.M.S.: Lieut.-Col. J. C. Robertson, C.M.G., C.I.E.

Majors to be Lieutenant-Colonels: H. Kirkpatrick, F. D. S. Fayrer, P. K. Chitale, T. Hunter, W. R. Battye, D.S.O., G. Hutcheson, W. G. Liston, C.I.E., H. Boulton, (Brevet Lieut.-Col.) R. W. Anthony, E. F. G. Tucker, G. E. Stewart, F. S. C. Thompson, T. S. Novis, J. W. Watson.

To be acting Lieutenant-Colonel: Major H. A. Williams.

Captains to be Majors: K. G. Gharpurey, P. S. Mills, D. C. V. FitzGerald, R. S. Kennedy, B. Higham, P. Heffernan, F. P. Wernicke, H. S. Hutchison, R. G. G. Croly, S. T. Crump, J. MacG. Skinner.

Temporary Lieutenants to be temporary Captains: L. M. Banerjee, U. L. Desai.

Temporary rank of Lieutenant in the I.M.S. has been granted to the undermentioned: Sisir Chandra Chatterjee, Maniketh Vythi Menon, Kshetra Mohan Ray, Bhuthapuri Krishnayya, Kalidas Bagchee, Leonard Philip Samarasinha, Kilolane Lawrence Singer, Alfred Ba Thaw, Rustam Jamshedji Tata, Khan Sahib, Ravu Venkata Rau, Annasamy Muthukrishnan, Sadashiva Chintamon Lele, Jagdish Chandra Gupta.

The King has approved the grant of the temporary and honorary rank of Lieutenant in the I.M.S. to the undermentioned: Chandi Pershad Trivedi.

The services of the following officers of the I.M.S. have been dispensed with: Temp. Lieut. Bishendas Soni (in consequence of medical unfitness), Temp. Lieut. Rash Behari Datta (in consequence of ill-health).

The transfer to the Temporary Non-effective List of the following officer has been approved: Major P. Heffernan (in consequence of ill-health due to field service).

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The opening article in the July issue of this journal discusses toxic action of carbonic and other weak acids on the meningococcus, Dr. J. A. Shaw-Mackenzie, the author, incidentally suggesting that CO_2 might also be made use of in syphilis of the central nervous system and in diseases due to protozoa. In observations on 250 cases of gunshot wounds of the peripheral nerves Major C. Noon comes to the conclusions, amongst others, that the diagnosis of an injury to a peripheral nerve ought to be made at the earliest possible time; that operations on injured nerves should only be done in well-equipped general hospitals, and by those surgeons who have ample experience in such cases; and that the extreme gravity of an injury to a peripheral nerve is not sufficiently realised by the general profession. An abridged version of this article has already appeared in our columns. The first part of a joint paper by Colonel G. T. Rawnsley, C.M.G., Lieutenant-Colonel R. A. Cunningham, and Captain J. Warnock on the Prophylaxis of Malaria is also contained in this issue of the journal, and Lieutenant-Colonel Gordon Holmes's article on the Symptoms of Acute Cerebellar Injuries as observed in Warfare is continued.

It is announced that medical officers of the Fleet who are carrying on the duties of a dental surgeon in addition to their proper duties as surgeons have been granted an allowance of 3*s.* a day, to take effect from August 8th last.

Medical News.

POST-GRADUATE COLLEGE, WEST LONDON HOSPITAL.—During next week clinics will be held each week-day at 2 P.M., Wednesday, Friday, and Saturday also at 10 A.M.

RABIES.—A case of rabies in a dog at Plymouth has been confirmed by the Board of Agriculture and Fisheries. Several suspicious cases have been reported and are now under investigation by the Board. In view of these circumstances, and as in more than one instance persons have been bitten by suspected dogs, the Board have made an Order prohibiting the movement of dogs out of Devon and Cornwall and requiring the control of dogs within a large area of those two counties. The public are warned that if in any case symptoms suspicious of rabies are observed the police should at once be notified.

THE BELL FUND.—Dr. S. A. Kinnier Wilson asks us to acknowledge donations to the Dr. J. H. Bell Fund from Dr. J. Dundas Grant (£2 2*s.*) and Mr. W. Gilchrist Burnie (£5 5*s.*). Subscriptions should be sent to Dr. Wilson, at 14, Harley-street, London, W. 1.

UNIVERSITY COLLEGE, LONDON.—Dr. G. D. Thane, Professor of Anatomy, has been appointed Dean of the Faculty of Medical Sciences, Dr. J. P. Hill, F.R.S., Jodrell Professor of Comparative Anatomy, remaining Vice-Dean.

DEVON INSURANCE COMMITTEE.—At the last meeting of the Devon Insurance Committee it was reported that there were 111,594 insured persons in the county, and about 98,000 of these were receiving medical benefit.

THE appointment of Mr. R. R. Cruise, C.V.O., F.R.C.S., to be Surgeon Oculist to the King has been cancelled and the following appointments are now announced: Sir George Anderson Critchett, C.V.O., F.R.C.S. Edin., to be Surgeon Oculist in Ordinary to His Majesty and Mr. R. R. Cruise to be Surgeon Oculist Extraordinary to His Majesty.

AN Order in Council directs that the Military Service (Conventions with Allied States) Act, 1917, shall have effect with respect to the United States and American citizens. American citizens in Great Britain are now liable to military service in the same manner as British subjects, and will have the same right in regard to exemption, application for which must be made before Oct. 4th. The tribunal is the same as for British subjects, except for the County of London, when application should be made to the special Local Tribunal for London, 171, Temple Chambers, Temple Avenue, E.C. 4.

Appointments.

BADGEROW, GEORGE W., C.M.G., F.R.C.S. Edin., has been appointed Aural Surgeon to the Royal Normal College and Academy of Music for the Blind.

MAYNE, B. J., L.R.C.P. Lond., M.R.C.S., Public Vaccinator for the Illogan District by the Redruth (Cornwall) Board of Guardians.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen Royal Asylum.—Med. Supt. £1000.

Ashton-under-Lyne District Infirmary, Lancashire.—H.S. £200.

Barnsley, Beckett Hospital.—Two H.S.

Birmingham City Sanatorium and Anti-Tuberculosis Centre.—Sen. Asst. M.O. £400.

Birmingham and Midland Hospital for Skin and Urinary Diseases, John Bright-street.—Medical man. 26 guineas. Also Anæsthetist. £20.

Bristol Education Committee.—School M.O. £500.

Bristol Royal Infirmary.—H.P. and H.S. £120.

Charing Cross Hospital, W.C.—Res. Cas. H.S.

Dorset County Council.—Female Asst. M.O. £350.

East Ham County Borough Education Committee.—Female Temp. Asst. School M.O. £400.

Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—Female H.P and Obstet. Asst. £50. Also Female Clin. Assts.

Great Northern Central Hospital, Holloway, N.—Res. M.O. £300.

Kensington and Fulham General Hospital, Earl's Court, S.W.—Res. M.O. £250.

Leicester Corporation Isolation Hospital, Groby-road.—Jun. Res. M.O. £250.

Liverpool, Royal Southern Hospital.—Two H.S. and Cas. O.

Liverpool, Toxteth Park Poor-law Institution and Infirmary.—Asst. Res. M.O. £300.

Manchester Education Committee.—Female Temp. Asst. School M.O. £350.

Metropolitan Hospital, Kingsland-road, E.—H.P. £150.

Metropolitan Hospital Tuberculosis Dispensary, Kingsland-road, E.—Temp. M.O. £500.

Much Wenlock, Salop, King Edward VII. Memorial Sanatorium.—Temp. Asst. Med. Supt. £300.

National Hospital for Paralysed and Epileptic, W.C.—Registrar. £100.

Northampton General Hospital.—Jun. H.S. £150.

Plymouth, South Devon and East Cornwall Hospital.—M.O. for Venereal Diseases Department. £500.

Portsmouth Royal Hospital.—H.S. £200.

Queen's Hospital for Children, Bethnal Green, E.—H.S. £100.

Queen Mary's Hospital for the East End, Stratford.—H.S.

Rotherham Hospital.—Jun. H.S. £150.

Royal London Ophthalmic Hospital, City-road, E.C.—Dep. Bacteriologist. £120. Also Refract. Assts. £100.

St. Helens, Lancs, Pilkington Special Orthopædic Hospital.—Res. M.O. £500.

Salford Royal Hospital.—Hon. Surgeon.

Sheffield Royal Infirmary.—Res. S.O. £200.

Shoreditch Infirmary Hoxton-street, N.—Med. Supt. £600.

Southampton County Borough Isolation Hospital.—Res. M.O. £400.

Sutton, Surrey, Downs Sanatorium.—Temp. Asst. M.O. £350.

Swansea Hospital.—H.S. £250.

Truro, Royal Cornwall Infirmary.—H.S. £150.

Warrington Infirmary and Dispensary.—Sen. and Jun. H.S. £250 and £140.

Whipps Cross War Hospital, Leytonstone, E.—Res. M.O. £1 per day.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Lincoln.

Births, Marriages, and Deaths.

BIRTHS.

BROWN.—On Sept. 5th, at Sheerwater Lodge, West Byfleet, Surrey, the wife of Captain L. Graham Brown, M.C., M.R.C.S. Eng., L.R.C.P. Lond., R.A.M.C., of a daughter.

CATES.—On Sept. 8th, at Laurel Mount, St. Helens, the wife of Joseph Cates, M.D. Lond., D.P.H. Camb., of a daughter.

CLIVE-SMITH.—On Sept. 5th, at Westminster Nursing Home, Chester, the wife of Captain Clive-Smith, R.A.M.C., of a son.

FARQUHARSON.—On Sept. 2nd, at York-place, Baker-street, the wife of Captain W. Farquharson, R.A.M.C., of a daughter.

O'SHEA.—On Sept. 8th, at Campsbourne-road, Hornsey, the wife of H. V. O'Shea, M.B., of a daughter.

PETERS.—On Sept. 7th, at High-street, Petersfield, the wife of Captain Rudolph A. Peters, M.C., M.B., B.C. Camb., R.A.M.C., of a son.

WALL.—On Sept. 3rd, at Lower Baggot-street, Dublin, the wife of Captain H. E. MacMahon Wall, M.R.C.S. Eng., L.R.C.P. Lond., R.A.M.C., of a daughter.

MARRIAGES.

BUCHANAN—HAIR.—On Sept. 6th, at St. Margaret's, Lossiemouth, Morayshire, John Scouler Buchanan, Captain, R.A.M.C., to Edith Margaret, elder daughter of J. H. Hair, Skerry Cliff, Lossiemouth.

DOORLY—BURT.—On Sept. 5th, Captain Arthur R. C. Doorly, M.R.C.S. Eng., L.R.C.P. Lond., R.A.M.C., to Winifred Burt, youngest daughter of Mr. and Mrs. Burt, of Witchampton.

FICKLING—O'CONNELL.—On August 31st, at Holy Trinity Church, Bembridge, Edwin Llewellyn Fickling, Captain, R.A.M.C., M.R.C.S. Eng., L.R.C.P. Lond., to Eileen Dora, only daughter of Mr. and Mrs. H. H. O'Connell, "Wooloomooloo," St. Ronan's-road, Southsea.

MILLER—KELSON.—On Sept. 3rd, at St. Wilfred's, Hayward's Heath, Captain Robert M. Miller, D.S.O., R.A.M.C., L.R.C.P. Lond., to Annie Mortimer, daughter of the late Thomas Mortimer Kelson, Captain, 6th Royal Regiment, and Mrs. Kelson, Birling, Hayward's Heath.

DEATHS.

IRONSIDE.—On Sept. 4th, at 50, Belsize-park, N.W. 3, Robert Adrian Ironside, M.D., aged 65.

MORRIS.—On Sept. 3rd, at his residence, Eaton-place, Brighton, the Rev. Joseph Morris, M.D., aged 75.

PROCTOR.—On August 12th, of wounds, John Proctor, Major, R.A.M.C., M.B., Ch.B. Aberd., of Ballater, Aberdeenshire.

TOLD.—On Sept. 3rd, at a nursing home, London, Margaret Todd, M.D. Brux., L.R.C.P. & S. Edin., L.R.F.P.S. Glasg., daughter of the late James Cameron Todd, of Glasgow and Rangoon, aged 59.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

EDITORIAL NOTICE.

In consequence of the pressure on our space and the shortage of paper, the Editor may be compelled to abbreviate communications, as an alternative to their rejection, when time does not allow them to be reconsidered by their authors.

Notes, Short Comments, and Answers to Correspondents.

A FORGOTTEN PHYSICIAN OF THE SECOND CENTURY.

Samuel, surnamed Schabour, and also Arioch, and mentioned in Jewish literature as Mar Samuel, was born at Nehardea (destroyed by Odenathus in A.D. 259) about A.D. 160. His father, Abba, was an important person there. Physically insignificant, being abnormally short and ill-developed, intellectually Samuel was great. He was educated at Nehardea by Rabbi Leir, a learned man who turned out several famed pupils. Samuel studied and specialised in various branches of learning, but his chief reputation and, indeed, the profession he finally made his own was that of the healing art. As a student he early made such progress in medicine that he was permitted to perform autopsies, and we have records of some of these. There is an account of a decision of his as to how large a piece of skull could safely be removed in case of fracture. He is quoted as stating after examination of an aborted fœtus that it was 41 days old, showing an intimate knowledge of the conformation of the product of conception at various stages. His opinion upon the abnormality termed spina bifida is also upon record. He must have carried out anatomical dissections, because there are extant quotations from his views on the limit of the spinal marrow. He appears to have been cognisant of the lacrymal gland and of the atrophy of which it is susceptible under certain circumstances in advanced age. His treatise upon the pathogenic symptoms following upon abrupt changes of diet is quite modern in thought. All varieties of regimen, he said, are liable to be the starting point of some malady.

For external diseases he sought natural causes for their occurrence and for their fatal termination; so for penetrating sores he accused the air of rendering them incurable. Also for wounds which finally poisoned the system, he said the cause was some virus upon the weapon that had inflicted the injury. In pathology he endeavoured to indicate for each malady the characteristic symptoms: for grave rhinitis, following probably a polypus ulcer, he said it could be detected by the offensive odour proceeding from the nasal organ. Migraine he attributed to excessive solitude and introspection. Magic as a curative he ignored. As to the propriety of attempting cures upon the Sabbath he was entirely favourable. He advocated the use of the speculum in order to ascertain if hæmorrhage proceeded from the vagina or the uterus. He was a great believer in bleeding as a remedy for many ills. Cleanliness was a main feature of his preventive teaching. The hands should be washed at least twice a day to prevent eye affections. He admitted his inability to cure three illnesses: that proceeding from eating green dates, if unripe and sour; the evil consequences of wearing a damp linen waistband as a girdle; and illness caused from going to bed after eating too hearty a meal and taking no exercise. Perhaps he also intended to convey that patients acting so foolishly were unworthy of being given remedial relief.

A SHORT WAY WITH COCKROACHES.

THE *Bulletin* of the Chicago School of Sanitary Instruction has been dealing with domestic pests, the latest issue describing a simple and effective way of ridding premises of these unpleasant arthropods. Commercial sodium fluoride mixed in equal parts with flour is dusted over the runways or applied with a dust-gun or powder-blower.

"The immediate effect will be noticed that the insects will come out of their hiding places, and after rushing about in a frantic manner for a time become paralysed and soon die. The dead or paralysed cockroaches may then be swept up and burned. As a rule premises can be ridden of roaches by this method in 24 to 48 hours."

The same mixture is said to kill caterpillars when fed on foliage that has been dusted with it. The fluorides should be used, however, with care and the inhalation of the dust should, of course, be avoided, as these salts have an injurious action on the human subject. Their use as preservatives in food is legally prohibited in the United States.

A. E. W.—As far as the necessity for sleep is concerned, there appears to be no essential difference between a brain worker and a manual worker. The function of sleep is to renovate the tired tissues, whether brain or muscle. The brain worker, so long as he is awake, uses every muscle in his body, as we know from recent calorimetric investigations, although, of course, in smaller degree than the manual worker. The manual worker's muscles are controlled by cells in the grey matter of the brain, in which it is that the first symptoms of "muscle" fatigue really appear.

A Lecture
ON
THE PREVENTION AND ARREST OF LICE-BORNE DISEASES BY NEW METHODS OF DISINFECTION.

Delivered before the Royal Society of Medicine on July 17th, 1918.

BY COLONEL WILLIAM HUNTER, C.B., A.M.S.,
PRESIDENT OF THE ADVISORY COMMITTEE FOR PREVENTION OF EPIDEMIC DISEASES IN EASTERN WAR AREAS, 1915–1917; COLONEL IN CHARGE OF BRITISH MILITARY SANITARY MISSION TO SERBIA, 1915; CONSULTING PHYSICIAN TO THE EASTERN COMMAND.

(*Concluded from p. 351.*)

I PROPOSE now to deal in more detail with the use and construction of the two new types of disinfectors, following this up with the results obtained in Serbia and in Salonika as I have already done for the Egyptian campaign.

CONSTRUCTION OF VAN DISINFECTORS.

1. The *original van disinfector* ("Van 1") was devised and formed by Lieutenant-Colonel Stammers, with the coöperation of two other officers of my mission, Lieutenants Ravenhill and Hill, and of Colonel Derocq, of the Serbian Engineers, in Kragujevatz, Serbia, towards the end of March, 1915. In forming it the choice of van lay between a wooden van and a meat van. The former was selected as apparently the easiest to improvise. The adaptation consisted in placing a narrow steam pipe round the floor of the van and close to its sides, connected up at end of the van by a T-piece with a similar pipe coming from the boiler of a small heating engine employed in Serbia for heating the railway carriages. The steam pipe had a few apertures of considerable size and several feet apart to let the steam into the van. The arrangements for the clothes were movable bars of wood stretching across the van, resting on wooden supports at the sides. Over these bars the clothes were spread out. The van was not completed in its details when I left for Nish at the end of March to arrange the formation of our sanitary train to which the disinfector was to be attached. The preliminary trial of it which I saw showed that it was most practical in its principle.

2. The *second van disinfector* ("Van 2") was formed by me in Nish from a meat van. The chief drawback to the adaptation of meat vans as disinfectors had seemed to be the presence in them of a perforated ventilating and cooling pipe near the roof, which would have to be removed. I found that this pipe could easily be connected up with the engine and used as the steam-pipe to convey the steam into the van, the steam entering at the roof of the van instead of on the floor level. Further, the van was lined with tin, which would greatly aid in the rapid heating of its walls, and it was already provided with numerous movable meat-hooks close to the roof, which could be utilised to hang clothes on. I therefore had it converted into a van disinfector. The adaptation was made in three days. On trial I found it worked admirably from the very first, the temperature rising to 97° C. in about half an hour, and lice-infected clothes, which I threw loosely on to the floor of the van, being thoroughly disinfected. The simplicity and ease of adaptation were great and obvious; the heat inside the van was most intense. As the result of my observations I had a similar van adapted as a bath van, as hereafter described, and utilised my experience in forming the van disinfector (Cairo Van 5511) in February, 1916, whose special features I shall now describe.

SPECIAL FEATURES OF THE VAN DISINFECTOR (VAN 5511).

3. This *third railway van disinfector* (Figs. 1, 2, 3) consists, as I have already related, of one or two ordinary railway vans, into which, by simple adaptation, steam can be discharged from the engine boiler of a *small locomotive engine*, which also serves the purpose of conveying it along the railway lines. Any old ordinary engine capable of developing steam and dragging two empty vans and a small guard's van for the use of the corporal in charge suffices for the purpose. Almost any sort of van can be converted; but the most generally suitable is an ordinary meat van, preferably lined with tin. The cost of adaptation of engine and van is only about £35–£50.

While essentially the same in principle as the form originally devised, the disinfector adapted in Cairo was modified by me in certain particulars, adding ten-fold to its rapidity and working capacity. Instead of a narrow steam pipe placed on the floor of the van close up to its sides, the steam pipe used is a wider one—2–3 inches in diameter, placed around the floor of the van, and about 2 feet from the sides. It is connected up by a flexible copper-wired coupling with a steam pipe of 1½–2 inches wide coming from the boiler and passing under the coal-box of the engine. The steam pipes in the van have a series of small apertures ⅛ inch in diameter—placed in two rows along the upper convexity of the pipe at intervals of 6 inches apart and alternately right and left—instead of a few larger openings originally deemed necessary. Wooden racks with open shelves, 3 feet wide and 3 feet deep, are placed around the van except at the doorways, the lowest shelf being 2 feet from the floor of the van, directly over the steam pipes, and also continued over the steam pipe at each end of the van. (See Fig. 3.)

The clothes do not require to be spread out, but are placed in their original bundles on the racks and, after the racks are filled, in the gangway provided with duck-boards, which is left free down the centre of the van. The pipes themselves are everywhere kept free from contact with these bundles by a bar of wood midway between the lower shelf and the floor.

On turning on the steam the van is filled at once with dense volumes of steam, which issues with great force in a finely divided spray in all directions, both outwards towards the sides of the van and inwards towards the gangway and immediately below the bundles of clothes on the racks, thus completely enveloping all the clothes. The walls of the van become hot in 5 minutes and burning hot in 10 minutes.

The water of condensation, which at once begins to escape from the van, at first cool, becomes warm in 5 minutes, hot in 10 minutes, and scalding in 15 minutes. After 20–30 minutes it lessens in amount, being itself converted into steam.

The temperature in the van, tested by a self-registering thermometer, rises to 102° C. in 10–15 minutes, and subsequently, even when placed enclosed in its own case in the centre of the largest bundles, e.g., 10 blankets tightly rolled up, it rises to 105° C. (or 221° F.) in about 20–30 minutes, according to the size of the bundles.

Factors in the disinfecting process.—The factors concerned in the remarkable disinfecting powers which this disinfector has proved to possess are the following: 1. The disinfecting power of current steam (steam in continuous motion) at the ordinary atmospheric pressure. 2. The great force under which the steam is driven into the van and clothes—a force derived from a pressure of 4–7 atmospheres (60–110 lbs.) developed in the boiler of the engine. 3. The great volume of steam available from the boiler of even a moderate-sized engine. These factors would be sufficient of themselves. 4. But they are powerfully aided by another very important factor—namely, the "heat of condensation" of steam which has been just set free from a pressure of 4–7 atmospheres on entering the van (i.e., from a temperature of 144° C. to 168° C.). 5. No attempt is made to develop any pressure in the van, steam being allowed to escape below and around the doorways.

Due to whatever cause the temperature in the van disinfector rapidly reaches 105° C., and this higher temperature ensures that the whole of the watery vapour in the clothes is in the form of steam at the end of the process. As they come out the clothes are not wet with warm water, but moist with steam, and if exposed at once to the air they become dry in a minute or two. This rapidity of drying greatly adds to the efficiency of the van disinfector, and suits it for massive disinfections on large bodies of troops, carried out frequently and rapidly whenever the opportunity presents.

DISINFECTION BY MEANS OF "BARREL DISINFECTORS."

While the "railway van disinfector" meets in most effective way the needs for disinfection of large bodies of troops or ordnance clothing, the needs for regimental disinfection are in my experience most simply and effectively

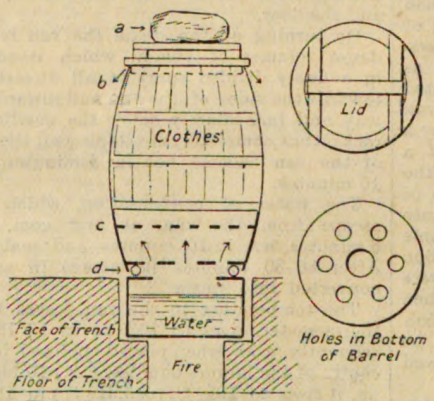
met by the *barrel disinfector*, first devised, as already described, for the work of the British Sanitary Mission in Serbia, and hence known as the "Serbian" or "Anglo-Serbian barrel." It was subsequently used as the simplest form of disinfection amongst our troops in Mudros and Gallipoli in the autumn of 1915; and in the Salonika Forces from early in 1916 (with interesting results now described), and in Egypt from October, 1915, but more especially from 1916 onwards. From the time of its first introduction and trial in Serbia on March 10th, 1915, it was at once welcomed and put into use by the Serbian armies, by whom it has since been continuously used with effective protection against typhus and relapsing fever. Its use was continuously urged by the Advisory Committee in all Eastern war areas during the two years of our work there (July, 1915–1917).

Nature of Barrel Disinfectors.

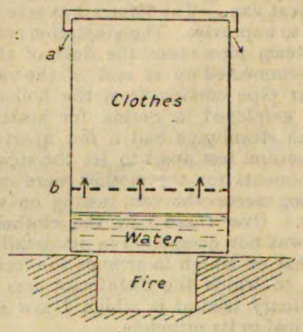
Simple and effective to a degree in the form originally introduced, its very simplicity has led to its being used in ways which have lessened its effectiveness, and for purposes for which it was never intended.

A sound wine or water barrel is taken, through the bottom of which one large central hole is made, with a circle of five or six holes around it, through which the steam can enter the barrel, which stands on a circular boiler of cast iron or galvanised iron. (Fig. 6.) To prevent any escape of the steam between the boiler and the bottom of the barrel a narrow sausage ring filled with sand is placed between the boiler and the barrel. The weight of the barrel presses this down, forming an efficient valve.

FIG. 6.



The wine barrel disinfector as introduced by Lieut.-Col. Stammers in Serbia.



Galvanised iron bin disinfector.

To keep the clothes in the barrel away from the holes in the bottom through which the steam enters a small frame made of two or three crossed thin bars of wood or wicker-work is placed inside the barrel over the holes and about 9 inches above the holes.

The barrel is provided with a wooden lid, purposely made heavy, with an edge which fits inside the barrel or overlaps it. The object of the lid is not to prevent entirely the escape of the steam, but to retard its escape—the purpose being disinfection by current steam, which escapes slowly and with some difficulty around the edges of the lid.

For transport the boiler and its sausage ring of sand are placed inside the barrel. Each barrel disinfector should have its own fire; and once the water is heated a very low fire suffices to keep it boiling. For practical efficiency each company of 250 men should have its own barrel disinfector; under the charge of its company N.C.O. responsible for seeing that the men of his company are kept free from lice. After the barrel is thoroughly heated and the steam escaping is too hot to be borne by the hand, the time required for disinfection of clothing is one hour; the temperature reaches 100° C. (212° F.).

Use of Barrel Disinfectors in the Field.

Where barrels are available there can be no simpler or more practical method of disinfection for the use of individual units. One barrel disinfector to each company (or four to a regiment) is capable of disinfecting the men of the company (or regiment) every two to three weeks. If the disinfector is in daily use whenever the company is in camp the men themselves get interested in it. To place their infected underclothing or trousers in the barrel for an hour appeals to them as a simple measure to free themselves from the discomforts of lousiness.

The object is to enable men to keep themselves free from lice by regular and systematic disinfection measures within their reach. As I commended its adoption to the Serbian Medical Society and to the authorities in Nish, "It is essentially a practical democratic measure for a highly democratic people."

It requires, in fact, no technical skill or appliances. A sound barrel, a suitable boiler, water, and a fire are all that are essential, and these are measures within the reach of every one at an initial cost of a few shillings. In Egypt and Salonika difficulties arose from the absence of suitable barrels. In wine-making countries, where no such difficulties exist, provision can be made for the supply of disinfectors in any number required.

TYPHUS AND RELAPSING FEVERS IN SERBIA, 1915.

I now turn to events in Serbia and give a few details of the urgent circumstances under which these new measures of disinfection were carried out by the British Sanitary Mission of 1915 and their work in connexion therewith. The time was the darkest hour of the epidemic—36,000 sick in hospitals, of which 15,000 were fever cases. The number of cases in hospital of typhus and relapsing fever at the time of our arrival was about 12,000; in the next three weeks it had risen to over 15,000.

These figures represented very inadequately the widespread character and ravages of the epidemics throughout all the towns and villages of the land, especially of typhus. In the first fortnight after our arrival (March 1st, 1915) the numbers of cases of typhus in hospitals rose from 3700 to 6000; in the next fortnight they had risen to 8100; its mortality was about 40 per cent. The difficulties in prevention that presented themselves owing to want of labour, wood, and appliances of any kind for sanitary work were overwhelming and seemed to hold out little prospect of any early arrest of the disease. The sequel was therefore the more interesting. Within seven days of our arrival a full *Programme of Prevention* was submitted in a series of eight communications sent to the Ministry of War and the Army headquarters, based upon our observations of the prevailing hospital conditions, the information received regarding the position of the armies and the knowledge gained as to the extent of infection of the railway system—really acting as a great river of infection throughout the land, carrying infection from the troops to the people and from the people to the troops, soldiers home on leave staying in crowded houses and causing or contracting widespread infection.

To break these conditions the programme (March 14th) included: "1. To break the lines of infection between the troops and the rest of the country by establishing a big quarantine and cleansing station just behind the three main armies. (Preliminary preparations at once put into force.) 2. Stop all railway communication for a time to interrupt even temporarily the conveyance of infection by the railway and permit a complete disinfection of all the railway stock. (This is to be put in force on March 16th.) 3. Stop all leave from the Army, and all soldiers on leave so far as is possible to be recalled before the railway communication is stopped to prevent possible reinfection of the railway after it has been disinfected. 4. The hospital problems presented the urgent need of some simple method of disinfection which can be rapidly improvised and provided for all parts of the country. Such a method has been devised adaptable to any large wine barrel (and these are all over the country). The appliance is so simple that it was made in 24 hours in the Arsenal here, tested here yesterday on clothes absolutely full of lice, and found most successful. And now orders are already given that hundreds of this simple appliance shall be made at the Arsenal (I have asked that a thousand and more shall be made) and supplied broadcast to all parts of the country to every village and town."

The barrel disinfectors were, as I have said, devised three days after our arrival in Nish on March 4th; they were constructed the following week, first tested and put into use in the Scottish Women's Hospital in Kragujevatz on March 13th, and arrangements were made for the construction and issue of 50 barrel disinfectors or more weekly from the arsenal in that town; subsequently also from the railway works in Nish.

Simultaneously, a programme of prevention had been submitted which included the formation of a disinfection and inoculation train, to include a railway van disinfector. Full authorisation was given early in April to the railway authorities by the Serbian headquarters to provide me with all facilities, and the work was carried out in a fortnight's time in Nish in accordance with the adaptations arranged.

The "English Mission Sanitary Train," as it was called, was completed on April 16th, inspected by the Prime

Minister and authorities in Nish, and arrived at our headquarters in Kragujevatz on April 18th, leaving next day in charge of Lieutenant-Colonel Stammers and a staff of 18 officers for the Army areas near the Danube. (See *Addendum*.)

The English Sanitary Train in Serbia.

The train consisted of: three third-class coaches with seats and partitions removed and adapted with tables for inoculation; disinfection and bath vans formed from meat vans; four third-class coaches adapted and fitted with stretcher-beds for sleeping accommodation of the Mission; and other wagons for the staff of Serbian orderlies and a Serbian officer—Captain Christitch—as military commandant of the train.

The *bath van* consisted of a meat van similar to that which I had adapted as a disinfector ("Van 2"). It was suggested by my experience with this disinfector van on its first trial. The heat in the disinfector van, which was lined with tin, was intense, and had the effect on me of a Russian bath. There was a large tank under the sloping roof over the wagon which could be filled with water and into which steam from the engine could be introduced, and douches could be fitted on the roof of the wagon. I asked that the adaptation should be made, and, like everything else done by the Serbian authorities in relation to this train, the work was carried out with characteristic good workmanship.

The final result was a train remarkably complete in its character, and unique in its preventive purposes for inoculation and disinfection, its chief features being its two excellent disinfection and bath vans with a heating engine capable of supplying steam to one or other or to both. On arrival at Kragujevatz, the original van disinfector ("Van 1") formed there from a wooden van was added, so that the train which went forward the following day contained two van disinfectors and one van bath.

On arrival in the Army area near the Danube it was found that during the period of four weeks before the train was formed the troops had been supplied with barrel disinfectors, and the use of these had already effected a marked reduction in the prevalence of lousiness and in the incidence of typhus and relapsing fever.

The need for the van disinfectors being thus greatest among the civil population south of the war area, the meat van disinfector ("Van 2") was detached from the train and attached with three others, subsequently formed, to the Serbian Ambulance Train under Captain Kopsha, for use as required in the various towns along the railway. I learnt from him subsequently that the work was successfully carried out up to the time of the invasion in the autumn of 1915, when among the spoils which fell to the invaders were doubtless included the English sanitary train, the English barrel disinfectors, and the English railway van disinfectors and baths. Colonel Soubatitch, of the Serbian Medical Department, informs me that articles have appeared in the Austrian medical press on van disinfectors and railway bath vans which suggest that the discovery of these in Serbia had proved of interest and value to them, although they were possibly unaware of their origin, indicated in Serbian characters alone upon the various carriages by the name "English Commission."

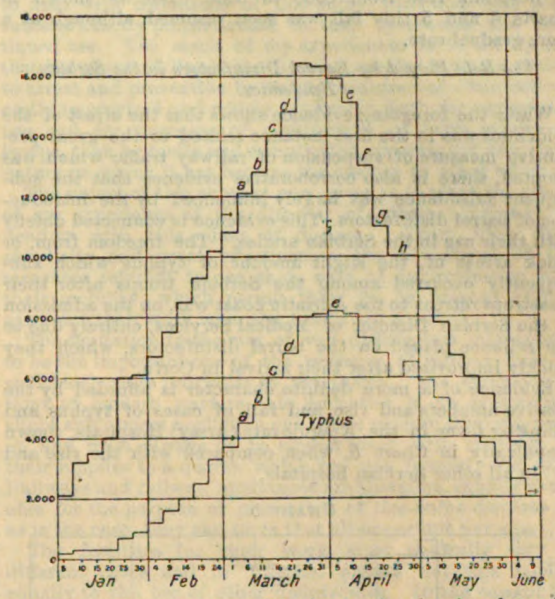
The keen practical interest taken by the Prime Minister of Serbia in the English Sanitary Train emphasised it as a measure of far-reaching practical importance, admirably fitted to meet the urgent needs of the circumstances. Of the van disinfectors and bath vans he ordered four more similar ones to be made, and of the barrel disinfectors he ordered 100 to be sent as types to the prefects of all the chief towns in Serbia, with instructions to form others in all the villages throughout the country.

If it was the fate of Serbia to include amid her other difficulties those of facing the greatest epidemic of typhus and relapsing fever recorded in the history of medicine, brought on her by the introduction of Austrian prisoners, it has also been her unique experience to see that epidemic more quickly checked and finally arrested in a shorter period of time than has ever before been witnessed, as the sequel now to be described shows.

Course of the Epidemics of Typhus and Relapsing Fever in Serbia.

The course of the epidemics of typhus and relapsing fever and their relation to the preventive and disinfecting measures adopted on March 15th ("*c*")—10 days after our arrival—are shown in Chart 4. The successive dates at which the measures were introduced are given at the foot of the chart, and the relationship between these and the course of the curve is too close to permit any reasonable doubt as to their connexion with each other as cause and effect.

CHART 4.



Combined totals of cases of typhus and relapsing fever in hospital in Serbia on dates specified (5 days intervals) (upper curve). Number of typhus cases (lower curve). Jan. 1st to June 9th, 1915.

March 4th: Arrival of Mission in Serbia; June 10th: Departure of Mission from Serbia. *a*, March 8th: Barrel disinfector devised and programme of prevention submitted. *b*, March 13th: Barrel disinfector made and tested. *c*, March 15th: Suspension of railway traffic, cleansing of railways, stoppage of all leave from the armies, increased measures of disinfection. *d*, March 22nd: "Van disinfector" devised ("Van 1"). *e*, April 5th: Van disinfector ("Van 2") formed in Nish; "van bath" devised. *f*, April 15th: Resumption of railway traffic. *g*, April 19th: English sanitary train (inoculation, disinfection, and bath vans) *h*, April 25th–30th: Sudden check in fall of epidemic 10–14 days after resumption of railway traffic.

Definite signs of a sudden check in the epidemics, as the result of the preventive measures commenced on March 15th ("*c*"), showed themselves about March 30th—i.e., exactly 10–14 days after the suspension of railway traffic. The number of cases in hospitals became stationary, indicating that the number of new cases admitted during the previous fortnight had only balanced those discharged or dead, instead of exceeding that number by a thousand a week as before. This evidence of arrest was followed by far more striking evidence—viz., a striking and rapid fall in the numbers of cases in hospital—from over 16,000 cases to 10,000 by April 25th ("*h*"). Had this fall been due to the natural course of the epidemics it should have continued uninterrupted, for among other factors favouring a fall at this period, the weather conditions which had been extremely bad when the fall set in had by this time (end of April) become summerlike. Nevertheless, the fall suddenly ceased ("*h*") about April 25th–30th (the number of cases of typhus actually rose from 6000 to 6500 cases). This check again occurred 10–14 days after the resumption of railway traffic on April 15th—i.e., after 10–14 days' incubation period of the diseases, indicating a fresh spread of infection as the result of this resumption. But this check was only temporary, for by this time all the other measures of disinfection and cleansing which had been put in force throughout the country had come into effect. The fall was resumed, and by the time the Mission left Serbia early in June, 1915, the diseases as epidemics were arrested. The total number of cases in hospitals was only about 2500, made up mostly of convalescent patients.

The suddenness in the arrest of these diseases by the measures taken was most strikingly shown in the case of typhus. As already seen, this had bounded up in a month from 3700 cases (March 1st) to 8400 cases (April 5th). From

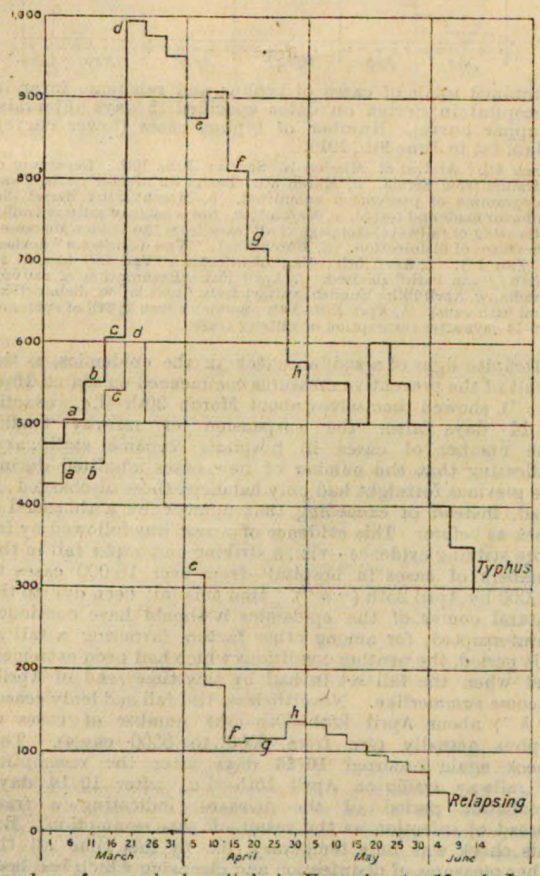
that date the numbers in hospital fell in 20 days from that figure to 6000 cases, denoting an extraordinary diminution in the number of new cases admitted during this period. The effect of resumption of railway traffic on April 15th was also most manifest in the case of typhus—viz., in 10 days' time (April 25th–30th) the fall ceased and the number of cases in hospitals rose from 6000 to 6300. But as shown in Charts 4 and 5 this fall was soon resumed, although at a more gradual rate.

The Rôle Played by Barrel Disinfectors in the Serbian Epidemics.

While the foregoing evidence shows that the arrest of the epidemics was in the first instance related to the great preventive measure of suspension of railway traffic which was adopted, there is also corroborative evidence that the subsequent subsidence was largely influenced by the introduction of barrel disinfectors. This evidence is connected chiefly with their use in the Serbian armies. The freedom from, or quick arrest of, the slight amount of typhus which subsequently occurred among the Serbian troops after their disastrous retreat to the Adriatic coast was, on the admission of the Serbian Director of Medical Services, entirely due to the reliance placed on the barrel disinfectors, which they quickly improvised after their arrival in Corfu.

Evidence of a more definite character is afforded by the relative numbers and rise and fall of cases of typhus and relapsing fever in the Kragujevatz (Army) Hospitals, shown graphically in Chart 5, when compared with the rise and fall in all other Serbian hospitals.

CHART 5.



Number of cases in hospitals in Kragujevatz, March–June.

a, March 5th: Arrival of Mission. *b*, Barrel disinfector put into use. *c*, Suspension of railway traffic (March 15th). *f*, Resumption of railway traffic (April 15th). *h*, Arrest in fall, April 25th and May 5th (10–14 days after *f*).

This group of hospitals served especially the active armies in the field and included the largest typhus hospital in Serbia (the 1st Reserve). Their importance as a whole may be judged from the circumstance that at the height of the epidemic at the end of March they contained 1000 cases of typhus (850 of them in the First Reserve Hospital), or 12 per cent. of the total cases in all the hospitals in Serbia, in addition to 500 cases of relapsing fever, or nearly 6 per cent. of the total. The data show that in the four weeks after our arrival——viz., March 1st–15th preceding, and March 16th–30th subsequent to, the suspension of railway traffic and adoption of other preventive measures (but before their effects could be manifested) the increase of typhus cases in hospitals was very marked and affected all areas about equally—viz., (*a*) Kragujevatz hospitals, from 500 to 1000 cases; (*b*) all other Serbian hospitals, from 3200 to 7150 cases. In the next four weeks the fall was: (*a*) In Kragujevatz hospitals, from 1000 cases to 572—a fall of 42 per cent.; (*b*) in all other Serbian hospitals, from 7150 cases to 5930—a fall of 17 per cent. The measures of prevention taken had thus produced a much greater proportionate effect on the army groups supplying the former than on Serbia generally. The only difference between them was in regard to the relative amount of disinfection available for the two. In the former barrel disfectors had been more and more put into use since their introduction on March 14th. By April 19th their effects in diminishing typhus in the troops had become very noticeable to officers in charge.

That effect, as now shown (Chart 5), declared itself very strikingly in the 42 per cent. reduction in the numbers of typhus fever cases (and even larger reduction in the numbers of relapsing fever cases) in the large Army hospitals in Kragujevatz during the month of April. It was also declared in the figures of admission into the chief of these hospitals during the periods in question. During March the number of new cases admitted was 1360 and the number of deaths 420; during April, when the disease was checked, the number admitted was 364 and the number of deaths 130. The rise on May 20th is explained by the circumstance that at this period all field ambulances in the army areas were evacuated prior to the advance of the Serbian armies, which by this time were in such good health and condition that an advance could once more be contemplated.

PREVENTION OF TRENCH FEVER.

In the case of trench fever the evidence I have is based on observations made during visits of the Advisory Committee to Salonika in May, 1916, and in February, 1917. During my two years' work in Egypt that form of fever was practically unknown. In Salonika, on the other hand, an outbreak of what was termed P.U.O. began early in January, 1916, and we found the hospitals full of such cases on our visit in May, 1916.—e.g., 67 out of 108 cases admitted into one Hospital in a week. On inquiry it was found that the disease had been introduced by a division of troops arriving in Salonika in December, 1915. Cases of what was regarded as influenza began to occur in January, 1916, and rapidly increased in number, the disease being eventually recognised as not influenza and provisionally designated P.U.O. Its characters resembled those of trench fever.

The probable connexion between this trench fever and lice was definitely raised at the time of our visit to Salonika in May, 1916, without, however, any definite proof of the connexion. The incidence gradually fell, the disease being overshadowed by the great outbreak of malaria which began in July, 1916.

At my visit alone to Salonika in February, 1917, the chief form of fever then prevalent was relapses from malaria, which formed one-half to two-thirds of the sick in advanced stations in hospital at that time. I heard nothing of P.U.O., and although doubtless present, its numbers nowhere approached the epidemic character attained early in 1916—e.g., out of 62 cases admitted in one day only one was classed as P.U.O.

The conditions in the valleys occupied by the troops being presumably as favourable to P.U.O. as those existing in 1916, the slight prevalence of trench fever was an interesting fact.

In the Valleys the arrangements with regard to disinfection engaged my special attention. In 1916 we had found that wide provision had been made, but too little use was being made, of barrel disinfectors, and I gave a special address and practical demonstration to the Salonika Medical Society emphasising the necessity for their continuous daily regimental use. In February, 1917, I found that better use was being made of barrel disinfectors in this area than in any war area previously visited.

If trench fever can be prevented by the adoption of regular regimental disinfection, then the conditions found were favourable to such prevention.

I am disposed to attribute the lower incidence observed largely to the interest taken in the disinfection by means of the barrel disinfectors in use, knowing from Serbian experience how strikingly and quickly the incidence of other louse-borne diseases, typhus and relapsing fever, can be checked by their use.

The whole circumstances connected with this incidence were investigated and made the subject of full report by my colleagues, Lieutenant-Colonels G. S. Buchanan, Andrew Balfour, and myself, constituting the Advisory Committee, on our visit in 1916, with special reference to the available data regarding its group incidence, its infectiousness, and especially its possible relation to lice.

In the light of subsequent conclusions on the latter point, the conclusions we expressed are interesting, viz. :—

"We think that for working purposes the theory of lice-carried infection holds the field, and all efforts to get rid of lice should be continued and developed with energy."

"We think it very important to make this form of disinfection as far as possible not merely a regimental but an individual matter; that all company officers, N.C.O's, and the men themselves by actual demonstration should be made to realise fully the object and advantages of barrel disinfectors and know the methods of working them. The forces here are well supplied with barrels."

The evidence regarding infectivity which we gathered included the following class of data. Within a Division it was usual to find that certain regiments had been conspicuously attacked, whilst those labouring near by were not affected. There was more trench fever among the divisions than in the base areas.

In the case of units there was a distinct period of prevalence lasting some six weeks to two months. Here and there were notable instances of group infection, three or four in the same tent being attacked in as many days, all presumably infected from the same source. Many combatant officers were attacked by the disease. Some smaller units suffered exceptionally severely in certain Divisions. Staffs attached to hospitals and field ambulances were frequently attacked. Thus, in one field ambulance to which most of the P.U.O. cases were admitted 13 cases occurred among its personnel, while in the two other field ambulances of the same Division there were only 5 P.U.O. cases. As regards lousiness, several of the units which suffered severely were at the time seriously infected by lice. This was particularly the case in the units of one Division, the one which had been free from trench fever on arrival in Salonika and which subsequently developed most cases.

Such was the position of matters in this area early in 1916 as regards trench fever—viz., a high degree of prevalence and infectivity; the need and importance of systematic daily disinfection strongly urged; the means for such disinfection provided in the form of barrel disinfectors. The sequel to these conclusions noted during my visit to this area in February, 1917, was the interesting one already described—viz., that P.U.O. cases were practically non-existent as compared with the prevalence in 1916.

With this there was the definite observation made and specially drawn attention to in my report—viz., that I had found better and more systematic daily use being made of barrel disinfectors in the war area than in any other area I had visited. Moreover, the two Divisions which I specially visited and in which I found these conditions were the two which had the biggest incidence of P.U.O. in 1916 and in one of which lice had been at that time most prevalent.

These two Divisions were the most advanced in the war area, and under the most favourable conditions for infection. Without disinfectors they would have been practically without any means of dealing with lice, except by the individual effort of ironing the clothes, a system which in one brigade was also being carried out in an exceedingly efficient and practical way. The arrangements in force included also demonstrations in the use of barrel disinfectors.

CONCLUSION.

The two great practical measures of disinfection introduced by the British Sanitary Mission to Serbia early in 1915 have proved by practical experience of their working, when introduced into the Eastern war areas by the chief officers of that mission, to be amongst the most serviceable measures of prevention employed in the war against lice-bore diseases.

The area where the problem is now presented is different, and the disease against which it is called for is different—viz., trench fever. The problem itself, however, is the same, and is capable of solution by the same methods.

In view of the widespread infection underlying trench fever, and its proved connexion with lousiness, the two methods here described are those most easily adapted for troops. I can confidently recommend them for wide use supplementary to or in place of any of the many other measures of disinfection or form of disinfectors now in use. They have been tried on a large scale in Serbia and elsewhere to deal with conditions of lice-borne infection, and with success exactly proportionate to their systematic and continued use. The result of my experiences is to satisfy me that the group of lice-borne diseases are far more amenable to arrest and prevention by simple measures of disinfection, easily improvised and widely applicable both for regimental use and for purposes of disinfection of large masses of troops, than by costly and complicated apparatus of autoclave nature on which it has become the custom to place reliance.

The object of this account now given is to place the result of my experience at the disposal of others concerned in dealing with this class of disease. Apart from their simplicity and great effectiveness, the advantages of the measures referred to are their ease of improvisation and their mobility, which permit them to be created and to carry out their work wherever troops are situated.

The limitation to the use of van disinfectors may appear to be the important one of the presence of railway lines in sufficiently close proximity to the troops. But under conditions of modern warfare this limitation is an exceedingly slight and almost negligible one, since modern armies depend on and must always be in closest touch with railways for their supplies to a degree which was not formerly the case. Railways and railway appliances are therefore equally available for the purpose of prevention of lice-borne diseases if, as is the case, they can serve that all-important purpose.

The facilities for their work must naturally vary in different cases and in different areas; but this applies equally to the use of other disinfectors. In the case of the van disinfector here described, any difficulties connected with their use must be weighed against their great simplicity, ease of improvisation, working capacity, and effectiveness. These are of such a kind that one double van disinfector could, if necessary, carry out the disinfection of an army corps once a month at the following rates of work: a regiment in half a day; two regiments in one day; a brigade in 2–3 days; a division in 10–12 days; an army corps in a month. In other words, its working capacity is equal to, but far exceeds in ease and simplicity of working, that of 50 portable Threshes or other similar apparatus.

As regards regimental and company disinfection, all that is required is the use of a simple steam disinfector of the nature of the barrel disinfector, which can be improvised at a cost of a few shillings, or of an even simpler form, also introduced in Serbia—viz., a galvanised sanitary bin, placed over a fire, with a foot of water at the bottom, and an open wire or wooden grid over the water to keep the clothes off the water. One such barrel or bin disinfector for each company could meet its needs of disinfection against lice to a degree which would reduce to one-tenth, even if it failed to eliminate altogether, the incidence of louse-borne diseases.

Addendum.—The number of anti-cholera inoculations carried out in the first three days was about 25,000, and 35,000 in six days, and both in and from the train as a working centre these were continued at approximately similar rates till all the armies dealt with were fully inoculated in 4–5 weeks' time.

Corrigendum.—In Chart 2, p. 350, the words "week to week of a double van disinfector" should read "*day to day of two double van disinfectors.*"

DEATH OF DR. J. LAMBERT.—James Lambert, M.D. Glasg., M.R.C.S. Eng., L.S.A., of Birkenhead, died recently at the advanced age of 90 years. Dr. Lambert was apprenticed in early life to a medical man at Northwich. In 1855 he took his degree at the University of Glasgow, and in the same year secured the diplomas of the Royal College of Surgeons of England and of the Society of Apothecaries. He was medical officer to a transport during the Crimean War, and afterwards settled in Birkenhead, where he had lived ever since. For many years he was Poor-law medical officer and surgeon to the Birkenhead Borough Hospital, and was consulting surgeon to that institution until his health began to fail. He took great interest in surgical practice, keeping well abreast of current literature.

A COMBINED EMBARKATION AND BOAT DISTRIBUTION SCHEME

FOR HOSPITAL SHIPS AND AMBULANCE TRANSPORTS.

BY HENRY HEMSTED, M.D. BRUX., M.R.C.S., L.R.C.P. LOND.,

TEMPORARY MAJOR, R.A.M.C.; O.C. TROOPS, H.M.H.S. "NEURALIA."

THE object of this scheme is to segregate patients on embarkation according to diseases, nationalities, ports of debarkation, &c., and to furnish each man immediately with a ticket for his life-boat. The Graphic System is adopted and works admirably.

A.—*Requirements.*

I. Embarkation boards. II. Tickets. III. Life-boat board. IV. Blackboard.

I. *Embarkation Boards.*

Dimensions of embarkation boards.—5 ft. by 18 in. by ½ in. The top end shaped to indicate the bow of the ship.

Number of embarkation boards.—Three boards should suffice on the largest hospital ships. Occasionally, when wards are scanty, ground-plans of two decks may be combined.

Painting of embarkation boards.—These show a rough ground-plan of the various wards on each deck, indicating size, shape, and name or letter. Surgical wards are painted blue and medical wards red. Parts of the wards unavailable for hospital purposes are shown black. (See Figs. 1, 2, and 3, in which dots represent the blue areas and oblique lines the red.)

Each ward has painted on it:—(*a*) The total number of cots contained. (*b*) The names of the medical officers, sisters, wardmasters, and orderlies on duty in each ward, indicated by typed slips pasted on the boards. (*c*) The nature of the cases it is designed to hold—e.g., fracture cases (special beds), acute surgical cases, minor medical cases, enteric cases, dysentery cases, tuberculosis cases, miscellaneous cases, &c. When different nationalities are being embarked the wards allotted to them should be indicated in chalk on the boards, as also should the wards reserved for batches of patients for debarkation at intervening ports. (*d*) The ward areas may be subdivided by a white interrupted line into two or more sections. (These sections are also marked with a white painted line on the deck of the actual wards.)

II. *Tickets.*

Number.—One ticket for each cot on the ship.

Size.—3 in. by 1 in. is convenient.

Texture.—Strong, but not thick, paper, preferably coloured. (Permanent metal "tokens" might perhaps be used with advantage.)

Affixation.—Tickets are penetrated near the top by 2 in. bifurcated brass paper clips, the ends of which are passed through the embarkation boards in their appropriate ward sections. (If the beds in any section are very numerous it may be necessary to divide them or to design special fasteners.)

Numbering.—On the front is the letter of the ward and the number of the ticket, the bottom ticket being No. 1 and the top ticket showing the number of the full accommodation of the section—e.g., "D. 32." After embarkation the top number remaining on the board shows the number of cots vacant in that section. On the back of each ticket is the number of the patient's life-boat—e.g., "Boat 6."

Collection.—Tickets may be collected on debarkation, and will then serve as a check on the numbers transferred.

III. *A Life-boat Board.*

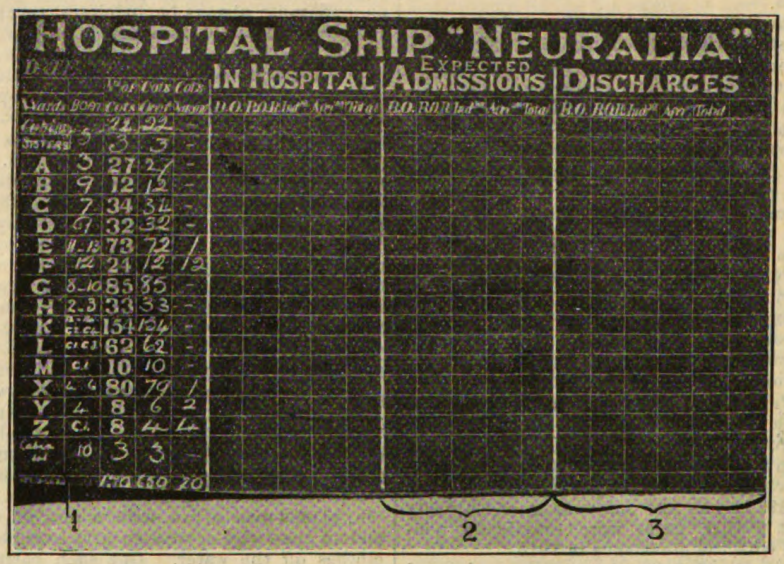
Description.—This is a rough ground-plan of the boat deck.

Complement of life-boat.—It should show a diagram of each boat, indicating its number, position, capacity, and allotment of patients, medical officers, and R.A.M.C. according to wards. The navigating officer and "skeleton" crew may also be indicated. Rafts should not be shown. (See Fig. 4.) In the illustration the boats are indicated by cards (dotted in the diagram) which are tacked on to the life-boat board. The cards are reversed when no sick are on board, and then show the detail by name of all R.A.M.C. personnel to the first eight life-boats. These would accommodate all souls when the hospital is empty.

IV. *A Blackboard.*

This is a daily record of the hospital and life-boat "state" and shows vacancies therein. It should be placed near the orderly room and designed as shown in the accompanying figure.

Blackboard showing Daily Record of Hospital and Life-boat "State."



1. A column for boat accommodation vacant could be inserted here. 2. All expected admissions are advertised here at first opportunity. 3. This column was used when the ship was a stationary hospital.

When a life-boat is short of its full complement the space becomes available for "lying" cases. The elaborations on the right-hand side of the blackboard are not essential, but the column headed "Expected Admissions" is valuable for announcing to the Matron, Chief Officer, Chief Steward, and R.A.M.C. generally, the number, composition, and approximate time of arrival of drafts of sick and wounded. On a hospital ship there appears no objection to advertising these details.

Three Desiderata.

For harmonious working of the scheme there are three desiderata:—

1. *Nominal rolls.*—The O.C. troops should be enabled to inspect all nominal rolls of sick at least ten minutes before embarkation begins. (Serial numbers running right down the left-hand column of nominal rolls, with a corresponding number on the backs of patients' tickets, greatly facilitate checking at embarkation and debarkation. "Lying" cases should be shown on nominal rolls.)

2. *Boat accommodation.*—There should be sufficient room in the ship's boats for all sick and a reasonable proportion of the ship's and hospital staff. (The balance would be compelled to use rafts in an emergency, but it would savour of indelicacy to give a sick man a *ticket* for a raft.)

3. *Transfers.*—Inter-ward transfers after embarkation must be notified to the orderly-room. When the above system is adopted these are extremely rare.

B.—*Routine.*

1. *Abstract of nominal rolls.*—The O.C. troops procures a rough abstract of patients for embarkation, noting specially:

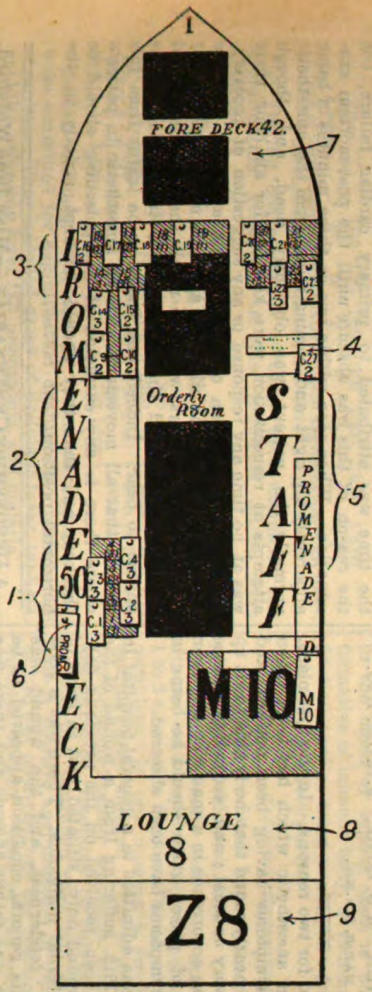


Fig. 1.

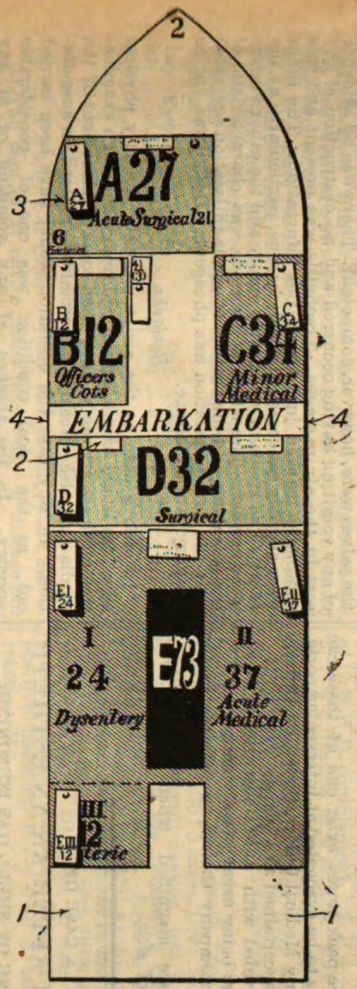

Fig. 2.

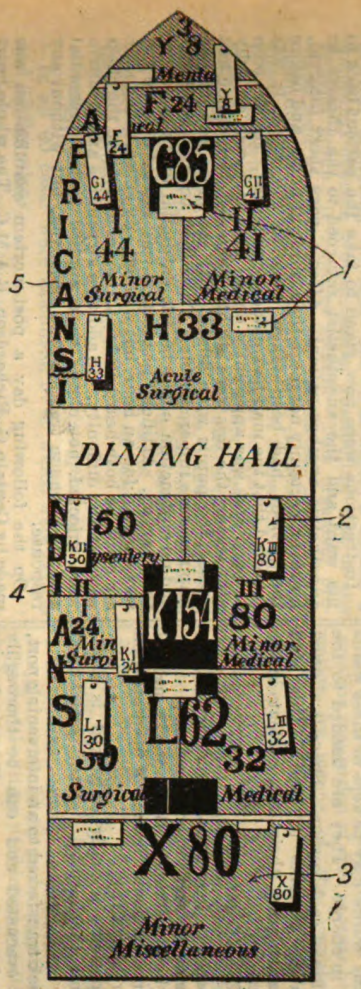

Fig. 3.

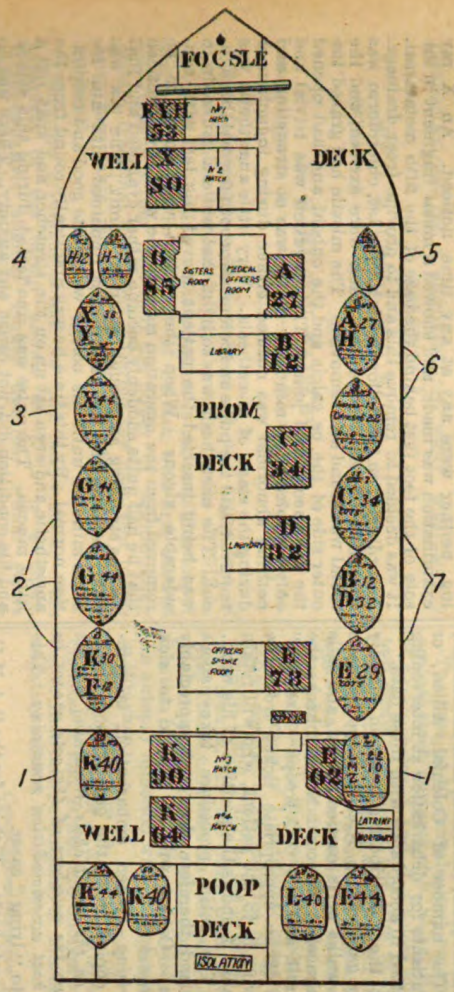

Fig. 4.

FIG. 1.—*Shade deck.*—1. Cabins for sick sisters. 2. Cabins for nursing sisters. 3. Cabins for sick officers. 4. Cabins for chaplains. 5. Cabins for medical officers. *6. Emergency accommodation on promenade deck. 7. Emergency accommodation on fore deck. *8. Emergency accommodation in "lounge" (for T.B.'s). *9. Emergency accommodation on poop deck (isolation).

* 6, 8, and 9 are on the deck level above the "shade deck."

FIG. 2.—*Saloon-level deck (chiefly used for "lying" cases.)*—1. Latrines. 2. Irrigating station. 3. Large cots for fractures. 4. Embarkation gangways which could also be used for transferring "lying" cases to boats.

FIG. 3.—*'Tween decks.*—1. Names of sisters, medical officers, and orderlies (typed). 2. A bunch of 80 tickets for K. III. 3. "X" ward is on the orlop deck. 4 and 5. This deck was formerly allotted to Indian and African natives.

FIG. 4.—1. Collapsible. 2. Life-boats. 3. A typical life-boat No. 6 (complement 56), viz.: (*a*) sick from "X" ward, 44; (*b*) chaplain, 1; (*c*) one N.C.O. and three R.A.M.C., 4; (*d*) the second officer, 1; (*e*) native crew, 6; total, 56. 4. Gig and mailboat. 5. Steam launch. 6. Life-boats. 7. Boats 7 and 11 which have space for "lying cases" and are in the best position for shipping same.

N.B.—The spaces indicated with oblique lines on diagram are chalked daily on deck and represent "rallying points" for the walking cases from the various wards. They are not required when there is boat accommodation for all on board.

(*a*) Number of "lying" cases. (*b*) Numbers of acute surgical, fractures (requiring special cots), acute medical, enterics, dysenterics, tuberculars, venereals, heat exhaustion, eye cases, &c. (*c*) The number of Colonial, Allied, or prisoners sick. (*d*) Patients for debarkation at intervening ports. Wards are allotted in accordance with these data.

2. *Distribution.*—At the "distributing" station (usually near the embarkation gangway) a N.C.O. inspects each patient's ticket as he walks or is carried aboard, and calls out the name and diagnosis. A second N.C.O. checks the name on the nominal roll, and the O.C. troops "sizes up" the patient and tears off an appropriate ticket from the embarkation board, giving it to the patient, who will retain it for the voyage, because it shows the position of his ward, cot, and life-boat. The entire procedure takes about 1½ seconds per man, and therefore does not appreciably delay an embarkation. Cabins will be allotted to sick officers in the same manner.

3. *Cabins; Summarising.*—When embarkation is completed the "state" is copied on to the orderly-room blackboard. *The numbers on the top tickets remaining on the embarkation board show the numbers of the cots vacant in each ward and also the boat accommodation remaining.* This latter may be allotted to "lying" cases.

4. *Allotment of orderlies to boats.*—Tickets for the R.A.M.C. employed in the various wards may be kept in these wards by the sister or N.C.O. in charge. They are handed to the orderlies at the beginning of each voyage. Space is allowed for them when allocating patients to boats. This plan ensures that orderlies accompany their own patients in the boats.

C.—*Advantages.*

1. Segregation of patients in groups according to their diseases, latrine requirements, and general welfare.

2. Certain cases may be placed under the care of a medical officer who specialises in a particular branch of his profession —e.g., eye cases, venereals, X ray.

3. The number of patients actually embarked is automatically registered and the hospital "state" ascertained at any moment.

4. When debarking sick transferred to an intervening port, a ward is completely evacuated and can be thoroughly cleansed and disinfected before a corresponding number of patients is embarked.

5. When two or more pack-stores exist one of these can be devoted to the wards to be evacuated at intervening ports.

6. The position of any Medical Officer, Sister, or Orderly in the hospital can be ascertained at a glance.

7. Each man is provided with a life-boat ticket *before sailing*, the first 24 hours being usually in a "danger zone."

8. R.A.M.C. staff accompany their own patients in the boats.

These advantages are magnified when dealing with numerous small drafts of sick.

A CASE OF

SUDDEN DEATH AFTER AN ANÆSTHETIC

IN A LATENT CASE OF SHELL GAS POISONING.

BY PHILIP TURNER, M.S. LOND., F.R.C.S. ENG.,
MAJOR, R.A.M.C.

THIS case is recorded for two reasons. In the first place, sudden death after an anæsthetic which has been taken without any unusual symptoms having been noticed, and where the patient is so nearly round that he is able to sit up and spit out mucus, is very unusual; and, secondly, because the possibility of such an occurrence in a man who has been exposed to the action of poison gases should be borne in mind, even though no symptoms have been observed.

Private H., aged 22, was admitted to a general hospital in France on April 30th, 1918, suffering from a wound of the right foot which had been received on the previous day. There was an entry wound only, situated just in front of and below the right external malleolus. There was a good deal of swelling and tenderness, and the wound was obviously infected. His general condition appeared to be satisfactory, though he was rather anæmic and there was slight pyrexia, due doubtless to the wound. There was no mention of gas poisoning on the field medical card, though a large number of men admitted from the same convoy, and who came from the same district, were gassed. The patient complained of none of the symptoms of gas poisoning, neither were any at any time noticed. An X ray examination was made, and showed a metal fragment in the sole of the foot just behind the base of the fifth metatarsal. It was decided to remove this and to provide freer drainage. Accordingly, on the following day, May 1st, chloroform was administered, the wound and track were excised, and the metal was found and removed. The missile had grazed the outer side of the os calcis and the cuboid and had opened the calcaneo-cuboid joint. The operation was trivial and only occupied a few minutes. There was no struggling, and nothing abnormal was noticed either during induction or during the stage of anæsthesia. Very little anæsthetic was required, and the pulse and colour were both normal throughout. The anæsthesia was so light that while a gauze drain was being inserted the patient moved his leg with considerable vigour. When the patient was about to be removed from the operation room to the ward it was noticed that he had quite suddenly become rather cyanosed and that he was straining as though about to vomit. The jaw was held forwards and the anæsthetist remained with him for some minutes until his colour was quite good and respiration normal. By this time he was practically round from the anæsthetic and even sat up on the stretcher and spat out a little mucus. The pulse was unaffected during this attack and his condition did not cause any anxiety. There was no vomiting and no excessive secretion of mucus.

Instructions were now given to take the patient back to his ward and the anæsthetist returned to the theatre to anæsthetise another patient. After a very short interval, however, certainly not more than three minutes, and before the patient had been taken back to the ward, it was reported that the man had suddenly collapsed. He was seen at once and was apparently dead. The face was an ashy grey colour, the lips were slightly cyanosed, respiration had ceased, the pupils were dilated, and the pulse and cardiac impulse were imperceptible. There had been no vomiting, and no obstruction could be felt on digital examination of the pharynx. Artificial respiration was started at once and was kept up for an hour, but without any effect, though the air could be both heard and felt to enter and leave the chest without any difficulty. In addition strychnine and pituitrin were injected, hot cloths were applied to the precordial area, and tongue traction was employed, but without any response.

On the following day a post-mortem examination was made by Captain G. Richardson, R.A.M.C. The whole heart was very dilated, especially the right auricle and ventricle; the valves were, however, competent. There was no evidence of any vomiting having occurred and no obstruction of any sort in the air passages. Tracheitis was present and was especially marked just above the bifurcation. The lungs were slightly congested and œdematous, particularly at the bases. The stomach was nearly empty and the other viscera were normal. The whole appearance was characteristic of gas poisoning, and the amount of cardiac dilatation suggested that the gas in question was phosgene. Death was due to primary cardiac failure.

Remarks.

In such a case as the above probably the only physical sign that would have been noticed from a thorough examination of the heart would have been some displacement of the cardiac impulse. Nothing abnormal was noticed on auscultation. In any case the operation would have been carried out, as the local condition was one of considerable urgency. In the absence of any vomiting or of any obstruction in the air passages the cause of death at the time was attributed to primary cardiac failure, but the reason of this was obscure until the post-mortem examination. When seen within two or three minutes of being apparently all right and coming round from the anæsthetic normally the patient was obviously dead, and though attempts at resuscitation were kept up for an hour there was at no time any response or any suggestion of recovery. He had already been observed to sit up once, and the probability is that he did this again or made some similar slight muscular effort, with the result that the dilated and weakened heart had thrown upon it a strain which it was unable to bear. Indeed, one lesson to be learnt from this case is that all movements after an anæsthetic in patients where there is any suspicion of gas poisoning should be checked, and that they should be kept strictly in the horizontal position.

A DEVONSHIRE CENTENARIAN.—Miss Jane Welsford, of Newton Abbot, celebrated the 104th anniversary of her birthday on August 21st.

TYPHUS FEVER:

OBSERVATIONS ON A SEROLOGICAL TEST (WEIL-FELIX REACTION.)

BY C. M. CRAIG, M.D. MANCH., D.P.H.,
CAPTAIN, R.A.M.C.; O.C. —— MILITARY LABORATORY;
AND
N. HAMILTON FAIRLEY, M.D.,
MAJOR, A.A.M.C.; PATHOLOGIST, —— AUSTRALIAN GENERAL HOSPITAL.

THE following is a brief account of our experience of the Weil-Felix reaction during the early months of 1918 in Egypt and Palestine. The reaction is an amplification of the work done by Dr. Wilson,[2] of Belfast, who first showed that typhus serum possessed the power of agglutinating certain intestinal organisms. During the past year it has been favourably reported on by Austrian and German workers.[3]

Characters of organism used in this investigation.—This organism of the strain known as X 19 is a short, Gram-negative, slightly motile bacillus, which grows under aerobic conditions only. On ordinary media it thrives, producing on agar and MacConkey's media a somewhat delicate growth, rather resembling that of the typhoid group; it liquefies gelatin. This organism produces acid and gas in glucose, saccharose, maltose, and mannite, but does not ferment dulcite or lactose. It produces indol freely, and acid without clot formation in milk. In our experience it has been non-lethal to guinea-pigs subcutaneously in doses of 2 c.cm. of 24 hours' broth culture.

Results of culture in typhus cases.—Cultures of blood in 12 cases yielded negative results. The urine, fæces, and sputum have been examined in 21 cases. An organism resembling the one described above has only once been isolated—i.e., in the urine of a patient on about tenth day of illness. This differed from the stock culture (X 19) in possessing much feebler agglutinating properties.

Agglutinating Phenomena in Definite Typhus Fever.

In all 90 cases were examined, 67 of which were British and 23 Egyptians.

Certain cases yielded rather anomalous results: 1. In one case agglutinins were not noted until two days after fever had subsided. 2. In the second case positive agglutination was not obtained until ninth day of disease. 3. In the third case two separate examinations of serum during second week of disease yielded negative results. In all other cases agglutination reactions were noted in the first examination.

(*a*) Forty-five British cases (in whom time incidence of illness was definitely known) were examined during the pyrexial period. The titres of the agglutinations obtained were as follows:—

Day.	Cases.	Titre.
4th	6	1/10, 1/10, 1/40, 1/50, 1/100, 1/1000.
5th	10	1/10, 1/10, 1/10, 1/40, 1/50, 1/50, 1/50, 1/50, 1/80, 1/160.
6th	6	1/50, 1/50, 1/50, 1/80, 1/100, 1/320.
7th	3	1/10, 1/20, 1/320.
8th	6	1/40, 1/80, 1/100, 1/640, 1/1000, 1/1280.
9th	2	1/20, 1/40.
10th	6	1/160, 1/200, 1/320, 1/320, 1/640, 1/1280.
11th	1	1/40.
12th	2	1/20, 1/640.
13th	3	1/80, 1/640, 1/280.

(*b*) The sera of 21 native cases (exact day of disease not definitely ascertained, probably all in second week of illness) gave positive reactions as follows:—

Titre	1/10	1/20	1/50	1/100	1/200	1/1000	1/2000
Cases	5*	3†	2	6	2	2	1

* One of these cases four days later, showed agglutination with 1/50.
† All showed an agglutination of 1/50 two days later.

(*c*) During convalescence 24 cases were examined and agglutination reactions in the following titres were obtained:—

Day.	Cases.	Titre.
2nd	1	1/20
5th	1	1/40
6th	2	1/1280, 1/2560
7th	1	1/320
8th	1	1/640
9th	2	1/160, 1/1640
12th	1	1/320
13th	1	1/50
14th	1	1/200
15th	1	1/640
21st	1	1/100
22nd	2	1/50, 1/320
26th	1	1/100
27th	2	1/100, 1/100
29th	1	1/10
31st	1	1/100
33rd	1	1/50
34th	1	1/100
37th	1	1/100
60th	1	Nil.

Control reactions.—The sera of 70 known negative cases were examined for agglutination against this proteus-like organism. They included cases of undulant fever, typhoid, syphilis, relapsing fever (30), pneumonia, and malaria.

In three cases a slight reaction was obtained in a dilution of 1/10; these occurred (1) in a healthy, much inoculated orderly; (2) in a case of acute pneumonia; (3) in an indefinite pyrexia, probably enterica (the serum gave a complete reaction in dilution of 1/10 against *B. paratyphosus B*, and in 1/100 against *B. typhosus*).

The sera of 10 convalescent typhus patients were tested against stock cultures of *B. Shiga*, *B. Flexner-Y*, *B. typhosus*, *B. paratyphosus A* and *B*, *Cholera vibrio*, *M. melitensis*, and two strains of *B. coli*, one true to type, the other atypical. The serum of one case agglutinated the typhoid bacillus in a dilution of 1/100 (inoculated against T.A.B.). One serum agglutinated *M. melitensis* in a dilution of 1/10. These were the only exceptions; the remainder failed to give any reaction even in the lowest dilutions.

In a group of 7 additional cases of typhus which were tested against stock cultures of *B. typhosus* and *B. paratyphosus A* and *B* during the pyrexial period 6 yielded negative results. In the other case, who had been inoculated with T.A.B. nine months previously, *B. paratyphosus A* and *B* yielded a positive agglutination with patient's serum in dilution of 1/40. *B. typhosus* yielded agglutination in 1/1280. An autopsy infection with *B. typhosus* was definitely excluded in this case.

Note.—Tested in a dilution of 1/10 against standard immune serum for *B. Shiga*, *B. Flexner*, *B. typhosus*, *B. paratyphosus A* and *B*, and the cholera vibrio (prepared by the Lister Institute), emulsions of this bacillus gave completely negative results.

Complement-fixation Reaction.

As the sera of typhus patients agglutinated in high titre a saline suspension of this proteus-like organism, an investigation by means of the complement-fixation method, originally devised by Bordet and Gengou,[4] was made.

The antigen used was a fresh saline (0·85 per cent. saline and 0·5 per cent. phenol) suspension prepared from a 24 hours' growth of this organism on agar slopes. The technique employed was similar to that used in the ordinary quantitative Wassermann reaction. Six and 12 minimum hæmolytic doses of complement were used in this test. A serum was regarded as yielding a positive result if in the presence of this bacterial antigen it fixed at least six M.H.D. of complement. In the first stage of the reaction quantities of antigen, (?) immune serum, and complement were mixed together for one hour at 37° C. Subsequently, sensitised sheep's corpuscles were added, and final readings were made after another hour's incubation at 37° C. The amount of complement fixed by pooled negative sera plus the amount of bacterial antigen used in the test did not exceed two M.H.D. of complement.

The results were recorded as follows:—1. P ++++ fixation of 12 M.H.D. complement. 2. P +++ fixation of 9 M.H.D. 3. P ++ fixation of 6 M.H.D. 4. P + fixation of 3 M.H.D. Only the first three readings are regarded as positive.

In all, 29 sera collected from typhus cases in different stages of the disease were examined.

Their agglutination reactions were as follows: 1 case, 1/2560; 5 cases, 1/1280; 7 cases, 1/640; 4 cases, 1/320; 3 cases, 1/160; 3 cases, 1/80; 3 cases, 1/40; 3 cases, 1/20. The results of the complement-fixation test were negative in 28 out of 29 cases. In the remaining case a positive reaction (P++++) was obtained. Even in this case the significance of the reaction was doubtful, as this serum exhibited distinct anticomplementary tendency in the serum control tubes.

Controls.—Forty-three sera from other cases (not typhus) were examined. Of these, 40 were negative and 3 yielded pseudo-positive reactions (one case of rheumatic fever, positive reaction, P ++++; 2 cases of syphilis positive reaction, P ++).

The formation of agglutinin for this proteus-like organism in the blood of typhus cases is not accompanied by the formation of immune body, as indicated by the complement-fixation reaction using as antigen a fresh saline suspension of this proteus-like organism.

Animal Experimentation.

Ten monkeys were experimented on—7 grivet (*Cercopithecus*) and 3 *Macacus rhesus*.

Of these animals four were used as controls. The six others were injected subcutaneously with one dose of 1 to 2 c.cm. of a 24 hours' broth culture of the proteus-like organism. In one monkey a second injection was given ten days after the first. Prior to inoculation all had negative complement-fixation reactions and all yielded negative agglutination reactions in dilution of 1/10 against this proteus-like organism with one exception only. In this case a positive agglutination of monkey's serum in a titre of 1/10 was obtained, but the reaction vanished in a higher dilution of 1/20. None of the monkeys showed signs of sickness or abnormal temperature after inoculation.

In all cases a positive complement-fixation reaction was obtained; in five cases within 12 days of inoculation. In the

sixth case the complement fixation, negative on the ninth day, became positive on the eighteenth day. The agglutinin response in this case was not as intense as usual. In all these cases, accompanying the appearance of agglutinin in the blood serum of the inoculated monkeys, immune bodies were produced also, which had the property of fixing complement in the presence of its specific antigen—namely, the proteus-like organism. The following gives the serological reactions in one of the experimental animals (Monkey Z):—

(A) Days after inoculation.				(B) Agglutination.		(C) Complement fixation.	
(A) ...	4	6	9	12	18	35	53
(B) ...	1/20	1/160	1/640	1/1280	1/1280	1/640	1/40
(C) ...	—	P++++	—	P++++	P++++	P++++	Neg.

Significance of Agglutination Reactions in Typhus Cases.

At the present time Austrian and German observers are agreed that this proteus-like organism must of necessity be a constant secondary invader in patients infected with typhus fever, in much the same fashion as certain authorities regard a secondary invasion with the *Streptococcus pyogenes* as occurring in scarlet fever. Such a conception, however, though explaining the appearance of agglutinin in the blood of typhus cases, is incompatible with the following facts.

1. Systematic cultural investigations of the urine and blood in cases of typhus fever over all stages of the disease do not yield, except very exceptionally, positive results for this proteus-like organism, and this despite the fact that it grows easily on all ordinary laboratory media—i.e., nutrient broth, agar, &c.

2. Serological investigations of typhus cases, while showing the presence of agglutinin for this proteus-like organism, failed to demonstrate the presence of any immune body; whereas serological investigations of monkeys inoculated subcutaneously yield both positive agglutination and complement-fixation reactions. If the "secondary invasion" theory were correct, then inevitably the immune body would be demonstrable in the sera of typhus cases.

This agglutination phenomenon, then, though yielding results of the greatest clinical value, is to be regarded as a pseudo-agglutination. Possibly it is of the nature of a group agglutination, and, if so, then the virus causing typhus may prove to be an organism allied to this proteus-like bacillus, but one which is resistant to cultivation on ordinary media.

The fact that the Wassermann reaction is not a specific test for syphilis in the strict immunological sense has not diminished its practical application as a diagnostic test for that disease. In similar fashion the appearance of an agglutinin in the sera of typhus patients for an organism which has no apparent relationship to the disease need not bias the student against its great diagnostic value in typhus fever.

Conclusions.

1. This agglutination test is an invaluable aid in the diagnosis of typhus fever.

2. Frequently the reaction appears only in the disease, and as a rule rapidly increases in titre.

3. A rapid agglutination in a dilution of 1/10 on Garrow's agglutinometer, while not absolutely reliable, is sufficiently suspicious to justify the isolation of the case. This is especially true of individuals uninoculated with T.A.B. or cholera. The serum of 50 uninoculated natives failed to give a reaction even in a dilution of 1/10. If the test be repeated at intervals of two days confirmatory evidence will, in the great majority of cases, be obtained.

4. This test is particularly valuable in the case of natives in whom it may be difficult to distinguish clinically between severe relapsing fever and typhus.

Note.—The agglutination was carried out in all cases on Garrow's agglutinometer; the results were read after five minutes' rotation and controls were used in every instance.

We have found Garrow's[5] agglutinometer of invaluable service and absolutely reliable. With this instrument, allowing five minutes for rotation, we find a dilution of 1/25 diagnostic. It is essential in order to obtain scientific and uniform results from a test of this description that a standardised and uniform technique should be adopted.

The method we have described has four great advantages: 1. The rapidity with which results can be obtained is necessarily of great value to the clinician, so as to enable speedy isolation. 2. The elimination of the feeble agglutinating power of normal serum in low dilutions upon this organism. This seems to take effect more readily if placed in tubes in mass contact with the organism than with the Garrow agglutinometer. 3. Economy in material, and the facility with which the technique can be performed in other than in an elaborately equipped laboratory. 4. The ease with which the agglutination can be read and its limits ascertained.

Our thanks are due to Captain P. H. Bahr, D.S.O., R.A.M.C., for assistance during the present investigation. To Colonel R. Fowler, A.A.M.C., commanding officer of —— Australian General Hospital, we are indebted for facilities in carrying out the experimental work on the section dealing with animal inoculation and complement-fixation.

NOTES ON

THE INTESTINAL PROTOZOAL INFECTIONS

OF 1680 MEN EXAMINED AT THE UNIVERSITY WAR HOSPITAL, SOUTHAMPTON.

BY DORIS L. MACKINNON, D.Sc.,
LECTURER IN ZOOLOGY, UNIVERSITY COLLEGE, DUNDEE.

WHILE acting as protozoologist at the University War Hospital, Southampton, from May, 1917, to March, 1918, I examined in the course of routine work the stools of 1680 patients. The results of my observations may be of interest to other workers at dysentery hospitals for three reasons: (1) the cases were examined as often as six times each; (2) while 914 of them were admitted as convalescent from dysentery (including colitis and enteritis) and severe diarrhœa, the other 766 were non-dysenterics, diagnosed typhoid, paratyphoid, trench fever, P.U.O., and so on; and (3) with less than 75 exceptions this large body of men had been invalided from France[1] or had not been out of Britain.

1. *Number of Examinations.*

The attempt was made, and, thanks to the excellent arrangements at this hospital, very successfully made, to examine each case at least six times before pronouncing him uninfected by *Entamœba histolytica*. Since the demand on accommodation for in-coming patients was always great, and since many of the men left the hospital after but a brief stay, the six examinations were made in the shortest workable period—i.e., a week—the first and sixth examinations corresponding with the two examinations required by the Army Council Instruction No. 205 of 1917.

Cases with 6 or more examinations				1549
,,	5 examinations only			33
,,	4	,,	,,	25
,,	3	,,	,,	20
,,	2	,,	,,	24
,,	1 examination	,,	,,	29
				1680

It will be seen from the above that the six-examination standard was well maintained. This is the first time, so far as I know, when a large number of cases has been systematically examined so often.[2] That the attempt to make so many examinations was justified is indicated by the following table of the findings of *E. histolytica*. The percentages of the total findings for which each examination is responsible will be seen to be closely in accord with those in the tables arrived at by calculation (Carter, Mackinnon, Matthews, and Smith 1917).

[1] The men were all questioned as to their previous travels, and we found that 447 had been at one time or other in tropical or subtropical regions.

[2] Dobell (1917) first pointed out the advisability of aiming at making six examinations per case. Carter, Mackinnon, Matthews, and Smith (1917) showed that it was well worth while to attempt this large number, since they calculated that three examinations reveal only 65 per cent. of the *E. histolytica* discoverable by six. The work done by Jepps and Meakins (1917) at the Hampstead Military Hospital is the only instance as yet on record in which the six-examination standard was consistently maintained throughout the investigation, but only 65 cases were examined.

TABLE I.

Examination.	No. of cases actually examined.	Total number found infected with *E. histolytica*.	Percentage of total cases examined.	Percentage of infected cases found by six examinations.
1st	1680	72	4·3	34 6
2nd	1651	103	6·1	49·5
3rd	1627	127	7·5	61·0
4th	1607	159	9·4	76 4
5th	1582	184	10·9	88·4
6th	1549	208	12·4	100·0

While six is probably the largest number of examinations that can be conducted in practice, it is certain that some infections go undetected. I found *E. histolytica* cysts in one case at the eighth examination, and a man sent as "clear" from Southampton to Barton-on-Sea after six negative examinations, found negative at Barton and returned to us for further observation and treatment, yielded *E. histolytica* then for the first time—i.e., at the ninth examination.[3]

2. *Total Infections Detected.*

Of the 1680 cases, 864 (= 51·4 per cent.) were found to be infected with one or more of the common intestinal protozoa, as follows:—

TABLE II.

Protozoon.	No. of cases infected.	Percentage of total cases examined.
Entamœba histolytica	209	12·4
E. coli	440	26·2
E. nana	303	18·0
Giardia (= *Lamblia*) *intestinalis*...	226	13·4
Chilomastix ("*Tetramitus*") *mesnili*	85	5·0
Trichomonas hominis	13	0·7

In addition, Wenyon's "I" cysts were found in 13 cases (= 0·7 per cent.)

These percentages of protozoal infection are not high, considering that the cases have been examined so often. Judging from previous experience with cases examined three times, I had expected to find by the sixth examination some 20 per cent. infected with *E. histolytica*. I saw, however, that whereas the material on which I had worked at Liverpool was mainly from dysenterics invalided, for the most part, from Salonica and Egypt, I was dealing at Southampton with a much larger admixture of non-dysenterics, and with men invalided, not directly from the East, but from France. These two considerations, I thought, might explain to some extent the relatively low percentage of *E. histolytica*. With this in mind, I therefore analysed the 1680 cases further.

3. *Comparison of Infections in Dysenterics and Non-dysenterics.*

TABLE III.

A. Dysenteric cases: number examined 914
B. Non-dysenteric cases: number examined 766

Protozoon.	A.	B.
	No. of cases infected.	
E. histolytica	123 (= 13·4 per cent.)	86 (= 11·2 per cent.)
E. coli	255 (= 27·9 ,,)	185 (= 24·1 ,,)
E. nana	189 (= 20·7 ,,)	114 (= 14·9 ,,)
G. intestinalis ...	146 (= 15·9 ,,)	80 (= 10·5 ,,)
C. mesnili	54 (= 5·9 ,,)	31 (= 4·0 ,,)
T. hominis	9 (= 1·0 ,,)	4 (= 0·5 ,,)

That is to say, both classes of patients harboured the same intestinal protozoa, but the percentages were slightly higher in the dysenteric group.

[3] I am indebted to my successor, Miss Jepps, for this information. Since the case was discovered to be "positive" after I had left the hospital I have not included it among the "positive" *E. histolytica* cases in this report.

This result is in agreement with the observations of other workers who have systematically examined the fæces of smaller numbers of non-dysenterics. Allowing for the difference in the number of examinations, my figures agree most closely with those of Smith and Matthews (1917, *a* and *b*) for 450 non-dysenterics from temperate as well as from tropical regions. Dobell's (1916) figures for 110 non-dysenterics are relatively higher than mine, but he was examining cases from Gallipoli and Egypt only.

We may further group our 766 non-dysenterics according to whether they have or have not a past history of dysentery or severe diarrhœa.

TABLE IV.

A. Non-dysenterics with history of dysentery or diarrhœa: number of cases examined 100
B. Non-dysenterics with *no* history of dysentery or diarrhœa: number of cases examined 666

Protozoon.	A.	B.
	No. of cases infected.	
E. histolytica	14 (= 14 per cent.)	72 (= 10·8 per cent.)
E. coli	27 (= 27 ,,)	158 (= 23·7 ,,)
E. nana	18 (= 18 ,,)	96 (= 14·4 ,,)
G. intestinalis... ...	9 (= 9 ,,)	71 (= 10 6 ,,)
C. mesnili...	4 (= 4 ,,)	27 (= 4·0 ,,)
T. hominis	2 (= 2 ,,)	2 (= 0·3 ,,)

The two groups are so unequal that it is scarcely fair to compare them closely; but, in a general way, it would seem that in non-dysenterics with a dysenteric history the protozoal infections are rather more numerous than in cases having no such history.[4]

4. *Comparison of Infections in "Eastern" and "French" Cases.*

With few exceptions, the cases were invalided to Southampton from France or had not been out of Britain. We were at great pains to discover what proportion of the French cases had been in the East[5] as well as in France, either during the war or at some previous time. We found that 447 of the 1680 (= 26·7 per cent.) had at one time or other visited the East. The bulk of the men—i.e., 1233—had never been further afield than the war zones in France and Northern Italy, and 34 of them had never been out of England. Six examinations of such a large number give some useful additional evidence of the frequency of protozoal infections, and more especially of *E. histolytica* infections, in temperate regions.

The two groups are compared in the following table:—

TABLE V.

A. Cases in the East: number examined... 447
B. Cases never in the East: number examined 1233

Protozoon.	A.	B.
	No. of cases infected.	
E. histolytica	72 (= 16·1 per cent.)	137 (= 11·1 per cent.)
E. coli	117 (= 26 2 ,,)	323 (= 26·2 ,,)
E. nana	85 (= 19·0 ,,)	218 (= 17 7 ,,)
G. intestinalis... ...	61 (= 13·6 ,,)	165 (= 13 4 ,,)
C. mesnili...	23 (= 5·1 ,,)	62 (= 5·0 ,,)
T. hominis	12 (= 2 7 ,,)	1 (= 0·08 ,,)

Though the two groups are numerically unequal, the smaller group is large enough to give a fair sample, and it would certainly seem that the percentage of *E. histolytica* infections is higher in the Eastern group—i.e., 16 per cent. as against 11 per cent. *Trichomonas* also seems to be more abundant in the Eastern group, but the total number of infected cases is too small for much meaning to attach to the percentages.

5. *Infections in Eastern Dysenterics.*

It appears, then, that the presence of a large admixture of non-dysenterics among the cases examined and the relatively

[4] Cf. Smith and Matthews, 1917, *a* and *b*.

[5] "The East" is here used to mean the tropics and those sub-tropical regions where amœbic dysentery is usually considered to be endemic. Northern Italy has not been so included.

small number of "Eastern" cases may both be factors, as indeed one would expect, in explaining the comparatively low percentages of *E. histolytica* infections found by six examinations of 1680 men.

This is further borne out by a consideration of the protozoal infections in such of the dysenterics as have at one time visited the East. Among the 914 dysenterics examined there were 280 giving such history. A comparison of these 280 men with the 634 dysenterics that had never been further afield than France or Northern Italy is shown below.

TABLE VI.

A. Dysenterics who had visted the East: number examined 280
B. Dysenterics who had never visited the East: number examined 634

Protozoon.	A. No. of cases infected.	B. No. of cases infected.
E. histolytica	56 (= 20·0 per cent.)	67 (= 10·6 per cent.)
E. coli	78 (= 27·8 ,,)	177 (= 27·9 ,,)
E. nana	53 (= 18·9 ,,)	136 (= 21·4 ,,)
G. intestinalis ...	41 (= 14 6 ,,)	105 (= 16·6 ,,)
C. mesnili...	14 (= 5·0 ,,)	40 (= 6·3 ,,)
T. hominis	7 (= 2·5 ,,)	2 (= 0·3 ,,)

The groups are of unequal size, but it is indicated that the dysenterics who had visited the East show a markedly higher percentage of *E. histolytica* infections than cases who have never been further than France—i.e., 20 per cent. as against 10·6 per cent.[6]

6. *Infections in British Cases.*

Examination of fæces of persons who had never been out of the British Isles has conclusively shown that all the common intestinal protozoa occur in this country.[7] Thirty-four of the men examined at this hospital who had been admitted with severe diarrhœa had never been out of England. They yielded the following infections:—

Protozoon.	No. of cases infected.	Protozoon.	No. of cases infected.
E. histolytica	1*	*G. intestinalis*	6
E. coli	5	*C. mesnili*	1
E. nana	3		

* An R.A.M.C. sergeant who had attended to dysentery patients on hospital trains.

7. *Size of* E. histolytica *Cysts.*

Cysts of *E. histolytica* measuring less than 10μ in diameter are now recognised by most workers who have studied the recent articles by Wenyon and O'Connor (1917) and Dobell and Jepps (1917 and 1918). In a batch of 200 cases Dobell and Jepps found 75 small-cyst infections, 127 large-cyst infections; 2 cases were passing both large and small cysts. These authors published later a paper to show that at least five distinct races of *E. histolytica* occur.

The 209 carriers with which the present paper deals showed a very large proportion of infection with small cysts:—

103 cases had cysts below 10μ only.
90 ,, ,, ,, above ,, ,,
16 ,, ,, mixed infections of the various sizes.

Dobell and Jepps (1918) "have obtained no evidence that races of *E. histolytica* producing cysts of any particular size are characteristic of infections acquired in any particular locality." While I admit that the numbers I have observed are too small to be of much statistical value, still I may note here that of the 103 small-cyst cases only 27 (= 26·2 per cent.) had been in the East, whereas 44 of the 90 large-cyst cases (= 48·8 per cent.) had been in the East. Of the 16 "mixed infection" cases, 6 (37·5 per cent.) had an Eastern history.

8. *Treatment.*

Of the 914 dysenterics examined, 43 had been diagnosed as "amœbic dysentery" in France before coming to us, and 24 of these are known to have had some emetine treatment there, most frequently with emetine bismuth iodide. Five of the treated cases were still passing cysts when they arrived at this hospital (one after emetine hydrochloride injections alone, three after emetine bismuth iodide alone, and one after both emetine hydrochloride and emetine bismuth iodide).

When accommodation at this hospital admitted of our retaining them for treatment, *E. histolytica* carriers were given a course of emetine bismuth iodide in 3 gr. doses for 12 days, and were examined daily after treatment for four weeks before being transferred to Barton-on-Sea. When the hospital was very full, it was found necessary to send on to the dysentery depôt at Addington Park, Croydon, all relapsing cases—i.e., cases passing cysts after treatment.

The following is a summary of the observed results of treatment:—

1. Of 131 men who had one treatment (130 for 12 days and 1 for 36 days), 62 were clear for 4 weeks afterwards and 69 relapsed.
2. Of 16 men who had a second treatment (15 for 18 days and 1 for 24 days), 6 were clear for 4 weeks afterwards and 10 relapsed.
3. Of 2 men who had a third treatment (for 18 days, and in one case with emetine injections during 10 days of the course), 2 were clear for 4 weeks after treatment and 0 relapsed.

Through lack of accommodation, 78 carriers were either not treated at Southampton or were transferred to Addington Park before they had completed the necessary four weeks' observation period after treatment.

Transferred without treatment	29
,, during ,, ...	11
,, immediately after treatment	15
,, in the 1st week ,, ,, ...	9
,, ,, 2nd ,, ,, ,, ...	10
,, ,, 3rd ,, ,, ,, ...	4
	78

Since 46 (= 58·2 per cent.) of the 79 relapses I observed occurred in the first week after treatment, 18 (= 22·7 per cent.) in the second week, and only 7 (= 8·8 per cent.) in the third and 8 (= 10·1 per cent.) in the fourth, the probability is that of the 14 men transferred to Addington Park in the second and third week after treatment some might safely have been cleared.

But the percentage of observed relapses after a first treatment is extraordinarily and disappointingly high—i.e., 52·6. When emetine bismuth iodide had been used for some time in the form of salol-coated pills, gelatine capsules were given a trial, but the percentage of relapses remaining still much the same, pills were resorted to again.[8] There was a great deal of vomiting recorded, and I think it almost certain that there was some evasion of a disagreeable treatment. It is at least suspicious that, while of the first 35 cases 23 were cleared and 12 (= 34·2 per cent.) relapsed, the next 25 cases gave no less than 21 relapses (= 84 per cent.). At this time the carriers were segregated in one hut; they were all cleared out together, at short notice, to make way for in-coming cases; after that, carriers were distributed through other huts, and "relapses" were less numerous again. It is exceedingly difficult, in a hospital not specially set aside for observation and experimental work, to ensure that the men all swallow their nightly dose. It might help matters somewhat if the medical officer in clinical charge of the patients worked under the direction of the officer in charge of the laboratory; the laboratory officer would then be kept better informed of the condition of the men, and by showing him what was going forward in the laboratory might interest the other more keenly in the carrier problem.

Twelve cases came from France diagnosed "*Lamblia* dysentery." Their field-cards stated of five of these that they had received methylene-blue treatment and were clear of cysts afterwards. Three of these five men passed *Lamblia* (= *Giardia*) cysts during their examinations after admission to this hospital. Dobell and Low (1916) have already shown that methylene blue fails to rid men of their *Lamblia* infections.

Summary.

1. From May, 1917, to March, 1918, 1680 cases (914 dysenterics and 766 non-dysenterics) were examined for intestinal protozoa. Only 131 had less than six examinations.

[6] Though the percentages are lower, the general result agrees with the findings of Dobell and Jepps (1918), where 1300 dysenterics from Eastern and French fronts, examined twice, yielded 12 per cent. *E. h.* infections, but, analysed into French and Eastern groups, gave 8·37 per cent. and 20 per cent. respectively.

[7] See Dobell (1917), Smith and Matthews (1917), Yorke, Carter, Mackinnon, Matthews and Smith (1917).

[8] Of 60 cases treated once with capsules, 33 (=55%) relapsed.
,, 67 ,, ,, ,, salol pills, 34 (=50·7%) ,,
,, 4 ,, ,, ,, capsules and pills, 2 (=50%) ,,

2. Thirty-four cases had never been out of England. The rest, with very few exceptions, came from France. But it was found that 447 had at some time been in tropical and subtropical countries.

3. 864, or 51·4 per cent., were infected with protozoa. *Entamœba histolytica* was found in 209 cases (= 12·4 per cent.), *E. coli* in 440 (= 26·2 per cent.), *E. nana* in 303 (= 18 per cent.), *Giardia intestinalis* in 226 (= 13 4 per cent.), *Chilomastix mesnili* in 85 (= 5 per cent.), and *Trichomonas hominis* in 13 (= 0·7 per cent.).

4. The 914 dysenterics yielded 123 (= 13·4 per cent.) carriers of *E. histolytica;* the 766 non-dysenterics yielded 86 (= 11·2 per cent.).

5. Among 447 cases (dysenteric and non-dysenteric) who had been in the East, 72 (= 16·1 per cent.) were infected with *E. histolytica;* of 1233 similar cases from England, France, and Northern Italy, 136 (= 11·1 per cent.) were infected.

6. 280 dysenterics who had been in the East had among them as many as 56 carriers (= 20 per cent.), whereas 634 French and English dysenterics yielded only 67 (= 10·6 per cent.).

7. *E. histolytica* cysts were found in one of 34 men who had never been out of England.

8. Of 208 *E. histolytica* carriers, 103 had cysts below 10μ in diameter, 90 had cysts over 10μ, and 16 passed both large and small cysts.

9. Of 131 carriers who were treated for 12 days with emetine bismuth iodide (60 with capsules, 67 with salol-coated pills, and 4 with capsules and pills), 69 relapsed after a first treatment. Of 16 who went on to further treatment at Southampton, 8 were eventually cleared.

10. Cases were examined daily for four weeks after treatment. At least 58 per cent. of the "relapses" took place in the first week.

11. Observations on 5 cases of "*Lamblia* dysentery" treated in France with methylene blue and declared free of the organism, do not suggest that this is an effective treatment.

I should like to acknowledge my great indebtedness to Lieutenant-Colonel Lauder, R.A.M.C., the officer commanding the University War Hospital, Southampton, and to my colleague, Captain William Fletcher, R.A.M.C., bacteriologist to the hospital. My thanks are also due to Miss Margaret Jepps, who kindly assisted me with some of the later examinations.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

TRENCH FEVER IN ENGLAND:

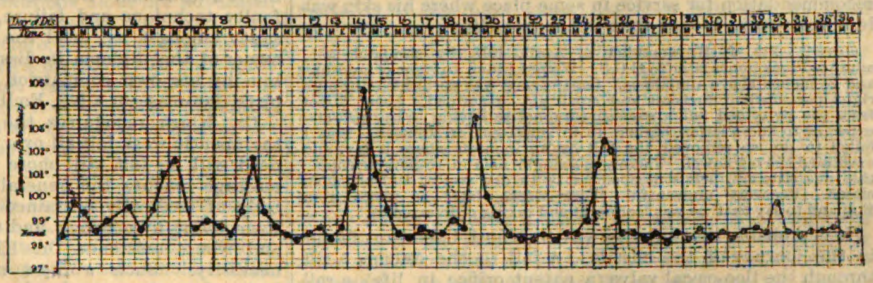
A CASE WITH NO HISTORY OF EXPOSURE TO INFECTION.

BY F. H. MOSSE, M.A. OXON., M.R.C.P.

THE following case did not occur in a civilian, but may be of sufficient value to be worth recording as an appendix to the interesting civilian case discussed by Dr. J. H. E. Brock in your issue of August 3rd and bearing on the likelihood of trench fever breaking out in the civilian population.

The patient was a lad of 18 who had just joined the Army. He was admitted to hospital on April 19th, 1918, complaining of headache and pain in the back. No other symptoms or physical signs were recorded at the time and the case was diagnosed as "influenza." He came under the writer's care a few days later, when the subsequent course of his pyrexia and the entire absence of catarrhal symptoms suggested an alteration in the diagnosis. The chart eventually showed a series of pyrexial attacks recurring at increasing intervals of from three to eight days. The patient felt acutely ill for about 12 hours during the attacks, with severe frontal headache and pain at the back of the eyes, which were kept tightly closed and caused him much pain if he attempted to move them. On one occasion slight nausea was present with the attack, but no vomiting. Between the attacks he was quite normal and said he had never felt better in his life. There were no abnormal physical signs in the heart, lungs, or abdomen; the spleen was not enlarged when I saw him, and the characteristic "shin pains" were absent. He was not conscious of having been lousy at any time, and there were no taches bleuâtres. At one time the intensity of the headache and the intermittent pyrexia suggested the possibility of cerebro-spinal meningitis, but there was no tenderness or rigidity of the neck tendons; Kernig's sign, Babinski's sign, and Brudzinski's signs were all absent; the knee-jerks were quite normal, and there were no eye symptoms or cutaneous eruptions.

Temperature Chart of a Case of Trench Fever in England.



The patient had never been abroad, but the possibility of an indigenous malaria has, perhaps, to be considered in these days. The irregular intervals between the attacks, the absence of rigors, and the comparatively rapid cure without quinine were, however, sufficient to negative this diagnosis. By a process of exclusion the case appears to be one of true trench fever.

The interesting point about the case, if this diagnosis be accepted, was that no history could be obtained of any exposure to infection. The patient had been sleeping in a hut, his bed being next the door, and his only "sleeping contact" had never been abroad or suffered from trench fever; further, no men in the camp had reported sick then, or since, with anything that could be diagnosed as trench fever; some men in the camp had been abroad, but none within a period of at least a month prior to patient's admission, and probably two months or longer.

It would seem likely, therefore, that he was infected either from a carrier, or from a mild ambulatory case, in which the disease had been so slight that the man had not reported sick.

If either of these hypotheses be accepted—and no originality is claimed for either of them—the possibility of civilians, as well as soldiers, being infected from such unrecognised cases is obvious, a possibility which it is well to bear in mind at the present time, when "influenza" is more than ever a ready-to-hand diagnosis.

NOTE ON TWO GUNSHOT WOUNDS.

BY J. J. M. SHAW, M.D. EDIN.,
MAJOR, R.A.M.C. (S.R.)

THE following notes on two cases—a hæmophilia and an errant shrapnel ball in the intestine—may be of some interest.

CASE 1.—Pte. T. C. admitted to C.C.S. in November, 1916, six hours after being wounded. Small but dirty wound of left calf; fragment of H.E. shell had cut deep fascia to extent of 1 inch and torn slightly subjacent muscle. From condition of dressings he must have bled pretty freely before admission. On operating wound presented no unusual features and was simply excised and cleaned, with ligation of two small bleeding points, before being dressed with eusol. Four hours later the dressings had "come through"; outer layers were changed.

On following morning patient looked blanched and ill; pulse-rate had increased overnight from 90 to 116. On inquiry I found that he had almost lost his life at age of 9, when his tonsils were "cut." An elder brother had died in childhood after some operation, the nature of which the patient did not know.

Patient was again anæsthetised, the wound rubbed with gauze and every oozing point ligatured, a series of very hot compresses applied, followed by a dry dressing. Six hours later I was called to him on account of acceleration of pulse to 136 and severe restlessness. The dressings were re-changed, and I gave him, for the serum effect, two 6 c.cm. ampoules of diphtheritic antitoxin. From that time oozing stopped and he quickly recovered.

The patient was later transferred to the base, with a strong recommendation for service in some place where his skin was less likely to be broken than in the front line.

CASE 2.—Pte. J. H. wounded in April, 1918, by shrapnel ball; admitted four hours later to C.C.S. Wound 1 inch to right of mid-line and 2½ inches above umbilicus. Laparotomy was performed through right para-median incision and small gut examined. About 8 feet from the pylorus I felt a smooth shrapnel ball lying in the gut, and expected to find a lesion higher up in small gut or stomach. This I failed to do, so removed the ball by an incision where it lay, and examined the big bowel. There was a single hole in transverse colon; this was stitched, pelvis mopped out with dry swabs, and abdomen closed. Recovery uneventful. Four weeks later he wrote from England to say that he was feeling fit and taking ordinary diet.

It is probable that gravity was the most important factor in the journey of the missile. A fall to the cæcum, a tilt through the ileo-cæcal valve (a patent orifice in life), a roll into the coils lying in the pelvis, the recumbent position, and an ambulance drive over French roads in the battle zone would serve to explain the vagrancy of the smooth ball, but the distance which it had travelled in the small gut suggests the aid of a so-called reverse peristalsis in the later stages of the journey.

A CASE OF JELLY-FISH STING SIMULATING AN ACUTE ABDOMEN.

BY ROBERT E. LORD, M.D., B.SC. LOND.,
AND
S. L. B. WILKS, M.D., B.S. LOND.

THE following case seems worth recording:—

A married woman, about 28 years of age, was brought to the house of one of us in a state of partial collapse, giving the following history. She had for years suffered from dysmenorrhœa, for which two operations had been performed in a special hospital. The bowels had acted normally on the morning in question. Immediately after bathing she was seized with violent pain in the abdomen and back, and also observed that she had apparently been stung on the arm by a jelly-fish, which she had not seen.

On examination about an hour after the onset of the symptoms she was restless and complained bitterly of pain in the abdomen, back, and right forearm, which was red, tender, and covered with beads of sweat. The abdomen was motionless, of board-like rigidity, and exquisitely tender to both light and deep pressure; there was no spasm of the back muscles; the liver dullness was normal in area, and intestinal movements were heard freely on auscultation. The temperature was 98° F., the pulse 96 and of fair quality, and the facies, though anxious, was not what one would expect in an abdominal catastrophe. The temperature rose to 99·4° in the evening.

One of us (R. E. L.) had, during the preceding two years, seen four cases of jelly-fish sting followed by extreme restlessness and emotional disturbance, varying amount of collapse, and tonic spasm of limb or neck muscles, the spasm coming on at intervals of a few minutes to a few hours after the sting; and it therefore seemed probable that the abdominal rigidity was due to this cause. This proved to be the case, and the patient was able to leave hospital, where she had been sent for observation, on the next day almost recovered but somewhat shaken by her experiences.

In the five cases of sting the jelly-fish was seen only twice by the patient, and in both of these was spoken of as being bright red in colour, no other feature being noticed.

Colwyn Bay.

Reviews and Notices of Books.

Massage and Medical Gymnastics. By EMIL A. G. KLEEN. Translated by MINA DOBBIE, M.D., B.Ch. R.U.I., Medical Officer, Chelsea Physical Training College. Illustrated. London: J. and A. Churchill. 1918. Pp. 618. Price 21*s.* net.

HAD we been asked to select any single foreign work on physico-therapeutics for translation into English it is probable that our choice would have fallen upon Kleen's great work. In it he gives us a faithful account of all that was best in Swedish methods of physical treatment at the time of publication of the original, now seven years ago, including lengthy chapters by Arvedson on Ling's Method of Medical Gymnastics, by Zander on Mechanical Gymnastics, and by Haglund on Medical Gymnastics and Massage in Orthopædics. For this alone Dr. Dobbie's careful translation will be very welcome in this country. But it is to the introduction that the reader will turn with the greatest interest, for the author there tells the story of the Swedish masseur who for many years has made of this country a happy hunting ground. The "gymnastic director" (D.G. for short) has come among us in his hundreds and has been accepted at his own valuation. Despite doubts and distrust engendered by faulty technique and failure, the D.G. has remained sacrosanct amongst us, until the halo around the head of the owner of the diploma is dissipated in the light thrown on him by his own compatriot, and perhaps the most eminent physician-masseur alive, Emil Kleen.

Dr. Kleen recognises the enormous need for physical therapeutic work felt all over the world, and thinks that the need will be felt still more as knowledge of the value of massage reaches the general public. To meet this need a body of medically untrained workers has arisen who earn their living by massage and to a less extent by gymnastics, and whose existence Dr. Kleen regards as an absolute necessity. Such workers must, however, know certain facts of anatomy and physiology, and in view of the uncritical enthusiasm which the splendid results of mechano-therapy are apt to arouse in medically untrained workers, they should learn from the beginning that there are many conditions which cannot be benefited by massage and gymnastics, and some which render all such treatment dangerous. The D.G. must, in short, be fully aware of the limitations of his own medical training, and that nothing less than a doctor's full training justifies completely independent work as a physical therapeutist. Unfortunately, Dr. Kleen has to add:—

"In Sweden everything possible has been done to create unsuitable conditions for mechano-therapy. ..... A school for physical treatment must live within the medical world, otherwise it is like a separate society which breaks away and artificially separates itself from and becomes hostile to the world to which it belongs. This has happened with the Central Institute. A more antagonistic spirit than that which rules there against medicine and its workers cannot be imagined, and except when there is some external advantage to be gained the institute will have as little as possible to do with the medical world."

The law of 1887, he goes on to say, crowned the work of destruction. It was entirely in the interests of the D.G.'s and against those of the general public. In enacting that no one except a doctor or a trainee of the Central Gymnastic Institute should have the right to treat by medical gymnastics, and this only according to the written prescription of a doctor, an absurd and mischievous view was given of the diploma. The D.G.'s troubled themselves very little about written prescriptions, and persuaded the public and themselves that their diploma possessed the same meaning in the domain of physical treatment as the doctor's degree in general medical practice.

The diplomats went on to persecute their rivals, and to exercise a tyranny as merciless and reckless as that of any socialistic trades union. After the D.G.'s had had it their own way for a quarter of a century, in the spring of 1911 the medical profession in Sweden expressed itself unanimously in favour of giving up the Central Institute as a school of mechano-therapy, and of the training of masseurs and medical gymnasts being taken over by medical institutions. And there the matter rests in Dr. Kleen's introduction.

In regard to the book itself, Dr. Kleen's style is marred by verbosity; his tale could be told in fewer words. While

every other form of physico-therapeutical treatment receives due mention, electricity is referred to grudgingly and quite omitted in important instances. Dr. Kleen grants it no place in preventing atrophy of muscles or in the treatment of severe affections of the joints. Insufficiency of the quadriceps is not mentioned as a cause of recurring synovitis of knee. The Bergonié treatment is ignored altogether, in contrast with the full and frequent description of the "terrain cure," whereas the former is less unattainable, cheaper, and often superior in effect in obesity and nutritional disorders and in a variety of heart cases. Experience has alsoshown it more valuable than massage and exercises in the treatment of constipation and of general debility. In the treatment of recent injuries the work of Lucas-Championnière and his disciples, such as Dagron and Castex, is not merely ignored, but Dr. Kleen frequently gives the credit due to them to other authors; and condemns without a hearing the methods advocated by Owen Thomas, Wharton Hood, and Robert Jones. Apart from such blemishes, a sense of proportion is sometimes lacking. Reference is made to restoring mobility of tendons by passive movements, but none to early prophylactic treatment. Ten pages are devoted to scoliosis without allusion to the elementary necessity of comparing the length of the two legs. The value of splintage is overlooked in many cases. Excluding the reference to Weir Mitchell treatment, less than one page is devoted to neurasthenia and its treatment. Vibrations alone are advocated for insomnia—we consider most inadvisedly.

The reader will do well, therefore, not to suspend his own judgment in studying Dr. Kleen's methods. In this spirit the book will be found a most valuable contribution to physico-therapeutical literature. It is admirably produced, and if some of the illustrations are indefinite in outline the fault is with the original, not the reproduction.

Medical Diseases of the War. By ARTHUR F. HURST, M.A., M.D., F.R.C.P., Temp. Major, R.A.M.C., Physician and Neurologist to Guy's Hospital, &c. Second edition, revised and enlarged. London: Edward Arnold. 1918. Pp. 320. Price 12*s.* 6*d.* net.

WE reviewed favourably the first edition of this work on its appearance some twelve months ago. The main alteration in the second edition is the replacement of the original chapter on war neuroses by no less than 11 chapters, covering some 130 pages, and dealing with various aspects of hysteria, neurasthenia, neuroses resulting from emotional over-action, shell shock, disorders of the special senses, &c., as exemplified in the war. These sections are of considerable value, representing, as they do, the outcome of a wide range of experience in neurological medicine. Dr. Hurst suggests that the term "shell shock" should be reserved for the condition following exposure to the forces generated by the explosion of powerful shells, in the absence of visible injury, a condition organic in origin and followed often by hysterical or psychasthenic symptoms. The definition is so clear that a little consideration will show the advisability of relinquishing it altogether. When a mass of coal falls on a miner's back he suffers from an organic concussion of the spine, and hysterical symptoms may well develop, but the condition has never been designated "coal shock." The hysteria or psychasthenia consecutive to shell shock is in no way different from the psycho-neuroses derived from other concussions or traumatic experiences; further, shell shock, considered as an organic phenomenon, is identical with concussion, commotio, contusion, or whatever degree of these the particular case may represent, and should be so described. Microphotographs, after Lieutenant-Colonel F. W. Mott, are given in the book, representing punctiform hæmorrhages and other quite unmistakable organic changes in the central nervous system, and these are stated as occurring in shell shock. Shell shock, in fact, notwithstanding its alliterative brevity, should be definitely given up as a clinical or pathological term.

There are many useful clinical descriptions of the phenomena of war hysteria and equally useful illustrations of their successful treatment. Hysterical spasm of accommodation or of convergence is moderately common among the war neuroses, but Dr. Hurst does not refer to it, apparently, in his chapter on disorders of vision. In his chapter on hysterical pain the writer declares that causalgia is "primarily organic in origin, but is later partly or entirely hysterical." A statement like this should, in our opinion, be qualified, as in its present form it is misleading. Causalgia occurs in many other peripheral nerves than the median, which is the only one specified in the book.

This book, in its second shape, should take a prominent place in the library of medical war literature.

Tumours of the Nervus Acusticus and the Syndrome of the Cerebellopontile Angle. By HARVEY CUSHING, M.D., Professor of Surgery at Harvard University, &c. Illustrated. London and Philadelphia: W. B. Saunders Co. 1918. Pp. 296. Price 21*s.* net.

Professor Cushing's monograph on tumours of the auditory nerve and the syndrome of the ponto-cerebellar angle is a model of what such special studies should be. In the first place it is based on a large personal experience, some 65 case reports being included in the book; from a consideration of this clinical and pathological material a synthetic study of symptomatology, pathology, and diagnosis is drawn; finally, Professor Cushing is a surgeon as well as a neurologist, and the chapter on surgical treatment represents the last word on the subject. No one speaks at present with more authority on this aspect of subtentorial tumours than he; his figures for operative mortality are unequalled, as far as we know, in his own or any other country; based on 43 operations, they stand at 13·9 per cent. Hitherto the mortality in operated cases has been painfully high, so that Professor Cushing may well be proud of his success.

A clear and important distinction is drawn by Professor Cushing between acoustic tumours and meningeal endotheliomata in the vicinity, which have often been confused by investigators. Considerable importance is assigned to the X ray picture, in particular to the condition of the internal auditory meatus—a point which has heretofore been rather neglected. His experience that some symptom referable to the fifth nerve occurs next in frequency to involvement of the eighth, showing a higher percentage than symptoms referable to the seventh, is in accord with the findings of other observers, but no explanation of this curious fact is suggested. In only 4 out of 30 patients was the corneal sensitiveness normal on the affected side, a sign of considerable value. With increasing pressure on the fifth nerve its ophthalmic division usually shows evidence of being next involved, although Professor Cushing does not mention this point. It is gratifying to find allusion to the difficult question of cerebellar fits, or "crises," as the author prefers to call them. He is inclined to ascribe their occurrence to varying tension of the cerebro-spinal fluid in the arachnoid cisterns; some at least of their usual symptoms are definitely of the nature of vagal attacks, with a sense of impending death, and seem more probably due to pressure on that nerve, direct or otherwise. Apparently, Professor Cushing in this series has seen instances of the so-called cerebellar attitude of the head, for more than one of his clinical photographs show the condition, which is referred to as "characteristic" without, it seems, being actually described in the text.

No neurologist can afford to be without this admirable monograph, which, apart from its intrinsic worth, is well printed and beautifully illustrated, with good bibliography and indices.

The Modern Treatment of Mental and Nervous Disorders. By BERNARD HART, M.D. Lond. A Lecture delivered at the Manchester University. London: Longmans, Green, and Co. 1918. Pp. 28. Price 1*s.*

THE lecture which is here reprinted was presumably given to a lay audience, but medical men generally, not excluding those with special experience of the subject, will find it profitable reading. Its singularly lucid style, moreover, gives pleasure in reading. Modern hypotheses as to the causation of mental disorder are not specifically mentioned, yet in a few words the essential points are brought out.

Dr. Hart holds an even balance between the school of thought which maintains that these disorders are the result of physiological processes occurring in the brain and other organs, all attempts at treatment being directed solely to these processes, and the other which holds that the disorders are the result of disturbed mental processes and that corresponding methods of treatment of a psychological order should be adopted. In the light of our present-day knowledge

Dr. Hart concludes that the only reasonable programme for dealing with mental and nervous disorders is to discover by systematic investigation all the causes at work, to attack each and every one by all the means in our power, to act on the body with every weapon of physiology, and on the mind with every weapon of psychology. In discussing the relative importance of the etiological factors Dr. Hart says :—

> We have, indeed, reached the paradoxical conclusion that, while in many 'mental' disorders mental factors play only a minor part amongst the causes which have produced them, in 'nervous' disorders these mental factors are of fundamental significance."

One criticism of the earlier part of the lecture seems called for. The phrase "chain of causes" is frequently used, and diagrams are introduced to show the various links in the chain. Thus, in one, the first link is "constitutional make-up"; the second, "condition of brain and other organs"; the third, "mental causes"; fourth, "bodily effects of mental causes"; fifth, "mental effects of bodily condition"; and lastly, the "symptoms of the disorder." To cure our patient we must break this chain somewhere, and the fundamental problem of treatment is "which link shall be attacked?" Other diagrams are given to illustrate different types of cases. Making allowance for the necessary limitation of any diagrammatic representation of such a difficult subject, we are doubtful whether the underlying idea itself is sound. The different factors of causation are not in series, but they react on one another in all kinds of ways. There is no chain to break. If a diagram could be drawn it would surely have to provide for influences impinging on the organism from many sides.

It is refreshing in these times to find a lecture on this subject without allusion to Freud or Jung, without mentioning the sub-conscious or unconscious mind, without reference to repression, substitution, psycho-analysis, or even hypnotism. But this is not to say that these subjects are ignored. Dr. Hart writes :—

> "Again everything is not on the surface of the mind, and the phenomena on the surface may effectually conceal elements of a very different kind which are lurking beneath. Thus a sparkling wit may conceal a gnawing sorrow, and boisterous and aggressive conduct may be the cloak beneath which is agonising shyness and diffidence. These buried elements often express themselves in astonishingly indirect ways," &c.

A little more light on what is meant by the "technical psychological knowledge" required in treatment would have been welcome. There is a touch of mystery here which surely is not intended. Again, some brief reference to the difficult question of sedatives in treatment would have been helpful. There is still a real danger that the early symptoms of nervous and mental disorders are suppressed and masked by the unwise use of sedative drugs. The lecture concludes with an appeal for the establishment of clinics and special departments of hospitals in which undeveloped cases of mental disorders can be treated in their early stages. The importance of organised investigation of mental and nervous disorders is urged, so that the "physiologist, chemist, and psychologist can attack the many problems that await solution and from every side."

To review a lecture so concise as this is necessarily difficult and Dr. Hart's terse sentences cannot be condensed without injury. The little book is a valuable contribution to psychological medicine, and is particularly opportune now that the strain of war has drawn so much attention to mental and nervous disorders.

Chemical Pathology. By H. GIDEON WELLS, M.D. Third edition. London and Philadelphia: W. B. Saunders Co. 1918. Pp. 707. Price 19*s.*

NOT until the whole subject of chemical pathology is put before the reader does he realise the vast amount which has been done by those working along the numerous indicated lines. Abnormal chemical processes are usually not the cause but rather the result of disease. By their detailed investigation, especially in those diseases in which metabolism is at fault, results have been obtained leading to successful treatment. We may instance psoriasis, where the body seems unable to excrete the products of nitrogenous metabolism; the patient recovers by diminishing and eliminating, as far as possible, food containing protein. Again, in diabetes, the new methods of dieting have given valuable results, though it is too early to speak of a cure. So many diseases are caused by bacteria that most of the chemical work in pathology has been devoted to the study of toxins, antitoxins, and the concomitant phenomena of agglutination, hæmolysis, and precipitins. Unfortunately, we are not yet near to solutions of the problems implied. The neutralisation of toxin by antitoxin appears to be a chemical process, but we do not know the actual process involved. There are still too many unknowns. The toxin is usually of the character of a protein, and there are some instances in which it may be glucoside. The antitoxin seems to be intimately connected with protein. Protein chemistry has advanced so much during the last 15 to 20 years that much is to be hoped from its meticulous continuation and application to pathology. Anaphylaxis is in some way or other bound up with the mechanism of antitoxin production; some advance has been made here, and once more protein chemistry seems to be at the root of the phenomenon. We must find out the chemical nature of toxin and antitoxin; we may then be able to prepare antitoxins in the chemical laboratory without recourse to animals.

Professor Gideon Wells in the third edition of his "Chemical Pathology" has well summarised the main chemical work in pathology. Curiously, the biochemical work on psoriasis is not mentioned, although it has been done by American scientists. Altogether the metabolic derangements are not treated in sufficient detail; the chapter on uric acid metabolism and gout is excepted. Here we have a very good description of the general process; the formation of uric acid is not the cause of gout. The author has relied upon the reader obtaining the information on metabolic disturbances from books on physiology and chemical physiology. A considerable portion of the book is devoted to a description of chemical physiological processes, and one asks whether it would not have been better to devote this book entirely to chemical pathology and omit the chemical physiology. The connexion of the two subjects is, however, so close that it is almost impossible to treat chemical pathology as a separate entity. There is no doubt that the description of chemical physiology serves to remind the reader and to impress upon him its relative value; often he would not understand the pathology without this reminder. The several chapters on toxins and antitoxins and allied phenomena show the present indefinite state of the subject, whilst those on retrogressive changes should clear up any confusion which still exists and the chapters on tumours, ductless glands, and inflammation invite further research.

War Surgery of the Abdomen. By CUTHBERT WALLACE, C.M.G., F.R.C.S. London: J. and A. Churchill. 1918. Pp. 152. Price 10*s.* 6*d.*

IN this volume Colonel Wallace collects the experiences in abdominal surgery over a period of 30 months, the greater part of which have already been published in our own columns and in the *British Journal of Surgery*. The collection is of great value as a record of what has already been achieved, founded as it is upon the practice of many surgeons working under different conditions and in different hospitals. The success obtained Colonel Wallace credits to the zeal of the stretcher-bearers and motor convoys, to the fixity of the fighting line, and to the abandonment of the tradition that operations cannot be peformed near a fighting area. He concludes with the query whether past results can be maintained when the armies get on the move.

Race Regeneration. By E. J. SMITH. London: P. S. King and Son. 1918. Pp. 223. Price 7*s.* 6*d.*

Mr. E. J. Smith is chairman of the health committee of the Bradford corporation and of the Bradford Insurance Committee, and may be regarded as the chief officer of a local "ministry of health." He goes the whole way in health matters, and bows neither to wealth nor tradition. He almost, in fact, ventures to look forward to a celebration of the day "when the boys come home," by welcoming them to a land which has opened the way to a nobler conception of life and its duties. His programme includes an extensive scheme of building reconstruction for working men and women, the endowment of motherhood, and the establishment of a Health Ministry. His book is well illustrated and may be read with interest by those who see the millennium in sweeping administrative reforms.

FRENCH SUPPLEMENT TO THE LANCET

Under the Editorial Direction of

Professor CHARLES ACHARD, PROFESSOR OF PATHOLOGY AND THERAPEUTICS IN THE UNIVERSITY OF PARIS.

AND

Dr. CHARLES FLANDIN, D.S.O., MÉDECIN-MAJOR DE 2ME CLASSE; CHEF DE CLINIQUE À LA FACULTÉ DE PARIS.

FOR four years British Arms have fought on French soil for the cause of Justice and Progress. The coöperation of the Allies, at first exclusively military, has grown in scope, and has extended to realms apparently without the range of the war. An ENTENTE has been replaced by a UNION. And this Union should exist after the war, and should coöperate in all fields of human activity. Our doctors must not remain outside the great *rapprochement*, which should make one the soul of Britain and the soul of France.

British and French soldiers now make one Army, and this is because they have learned to understand each other. That the British and French doctors should become the exponents of one scientific and moral organisation, it is necessary that they should understand each other.

The aim of this Monthly Supplement in THE LANCET is to enable British doctors to understand the theories and the researches of French doctors.

We propose to issue, in more or less monthly form, a general review of some big medical subject and an original article dealing with a particular question. We shall obtain these contributions from authors whom we know to be especially qualified by their researches and work to set out ably the results actually achieved, as well as the trend of ideas in France. In this way we aspire to assist our British confrères to a fuller understanding of French medical movements, and we shall be happy to serve them by placing them in relation with those of our workers whose researches interest them specially. If this Supplement leads to mutual interpenetration of the two medical worlds we shall be amply repaid.

CH. ACHARD.
CH. FLANDIN.

THE MICROBIC DIVERSITY OF THE ENTERIC FEVERS.

By Professor ACHARD.

THE French Dr. Louis, in 1829, gave the name of typhoid fever to a malady of which he discovered the characteristic intestinal lesion and in which he included numerous cases of febrile disorders described until then under such terms as "putrid fever," "fièvre adynamique," and others. The identity of typhoid fever, and its anatomical and pathological individuality, having been thus established, lengthy discussion ensued on the causes of the disease, so that two schools of view were formed. According to Murchison, the cause of the disease was a poison having its origin in decomposing fæcal matter (the pythogenic or autogenous theory), whether this fæcal matter proceeded or not from a patient suffering from typhoid fever. Those, therefore, who held this opinion admitted that the disease could develop without any direct transmission and was able to arise spontaneously. According to Budd, on the contrary, typhoid fever was due to a specific cause, and could not develop except by transmission from the infected subject.

The Typhoid Bacillus.

When the era of bacteriology arrived it seemed at first view that the question was decided. After the discovery of the typhoid bacillus by Eberth, in 1880, and the researches in 1884 of Gaffky, who isolated the bacillus in pure cultures, typhoid fever was considered in a practically unanimous manner as a microbic disease, produced regularly and exclusively by the bacillus of Eberth. But, nevertheless, the characteristics of this microbe remained from the beginning insufficiently precise. It was obvious that the microbe resembled the common germ to be found in abundance in the normal intestines, the coli bacillus described by Escherich under the name of *Bacterium coli commune*. It is probable that confusion occurred in this manner more than once in the analyses of fæcal matters and drinking-water, made with the object of ascertaining the nature and origin of different epidemics. Then, under a new form, the autogenous theory reappeared, according to which typhoid fever could arise without the transmission of the bacillus of Eberth. The Lyons school, notably Rodet and Gabriel Roux, claimed that the coli bacillus was able to transform itself, or to be transformed, into the bacillus of Eberth. The supporters of specificity, on the other hand, made every attempt to show the distinctive characters of the two microbes. First they pointed to the action of the microbes on lactose, the coli bacillus causing fermentation with the disengagement of gas in the culture bouillons, a phenomenon which does not occur with the bacillus of Eberth. The coli bacillus coagulates milk, and this again is not the case with the bacillus of Eberth (Chantemesse and Widal). Further, on the old cultures of Eberth's bacillus, while this bacillus is incapable of growing afresh, as if the medium was vaccinated against it (Chantemesse and Widal), the coli bacillus, on the contrary, is capable of growing (Wurtz).

Paracoli Bacilli.

Nevertheless, the coli bacillus was perceived not to be a microbe of a unique type, but to represent rather a microbic group comprising multiple types, among which certain resemble Eberth's bacillus, forming in a way intermediate links. I have described with Jules Renault in 1892[1] several of these types in urinary infections. Gilbert and Lion[2] then studied them in fæcal material, and have given them the name of paracoli bacilli (1893). Now, certain of these paracoli bacilli, as M. Renault and I have shown, do not ferment lactose; they do not coagulate milk at the temperature of the incubator, thus acting like Eberth's bacillus. Nevertheless, they acidify milk sufficiently to cause, if the culture is carried to boiling point, immediate coagulation. By this they are distinguished from Eberth's bacillus. Moreover, the paracoli bacilli grow on the old cultures of Eberth's bacillus, which sufficed to show that they are in no way identical with it.

A very important new differential sign should also be added to the preceding. The phenomenon of agglutination of microbes by specific serums allowed Grüber in 1896 to distinguish Eberth's bacillus from the coli bacillus and its various types. Then Widal, in June 1896, by causing the serum of patients attacked by typhoid fever to act on cultures of Eberth's bacillus, founded the method of sero-diagnosis, which has rendered such great service in practice. It was then seen that the serum of those patients agglutinated Eberth's bacillus, but remained without action on the coli bacillus and the paracoli bacilli.

Paratyphoid Bacilli.

Only a few months had elapsed since the first application of sero-diagnosis when I had occasion to observe with R. Bensaude[3] a patient whose symptoms were those of classical typhoid fever complicated by intestinal hæmorrhage, phlebitis, and pyelonephritis, and in whose urine we found a microbe a little different from Eberth's bacillus. This microbe was agglutinated by the patient's serum, but not by the serum of other patients suffering from typhoid. Reciprocally, the serum of this woman did not agglutinate Eberth's bacillus. This new microbe showed itself identical with another bacillus found some months previously in the pus of a sterno-clavicular abscess consecutive to an acute and ill-defined illness in a newly born baby. Thus, two samples of the new bacillus were distinguished from Eberth's bacillus by agglutination. Further, they were differentiated from it in that they developed on the old cultures of Eberth's bacillus. They resembled it, on the contrary, by their lack of fermentative action on lactose; not only, in fact, did they fail to form gas in lactose bouillon, but also they did not coagulate milk, even when this was carried to boiling point. In this they were distinguished from the coli bacillus and the paracoli bacillus.[3]

Nearer consequently to Eberth's bacillus than to the coli bacillus, this new microbe appeared to me to warrant the name of "bacille paratyphique." The demonstration of this microbe in patients suffering from typhoid infection constituted the first proof of the microbic plurality of these infections. Room was thus made, alongside of the Eberthian typhoid fever, for the typhoid fever associated with *Bacilles paratyphiques*, or paratyphoid fevers.

Our earliest work on the paratyphoid infection (November, 1896) found at first but little favour, because the unity of typhoid fever and the specificity of Eberth's bacillus appeared solidly established after the lively discussions to which the question had given rise. The following year (1897) Widal and Nobécourt,[4] having obtained from an abscess of the neck a bacillus identical with ours, as Brion recognised later, described it as a paracoli bacillus. In America some cases of paratyphoid infections were also published by Brill (1898), Gwyn (1898),[5] and Cushing (1900)[6] without the microbes found being designated under the name that we had proposed. Gwyn employed even the term paracolon bacilli.

Following on researches made at Hamburg by Schottmüller[7] the attention of bacteriologists and clinicians was definitely turned to the infections by *Bacilles paratyphiques*. Schottmüller employed this term without mentioning, or appearing to know, that it had been employed already in France four years before, nor that the infections determined by these bacilli, and similar to the Eberthian typhoid fever, had in that country been made the object of a description. The novelty in the researches of the German author consisted in the fact that the bacilli derived from his patient formed by their characters two distinct types, which were designated later by Kayser under names of type A and type B. The type B is identical with the bacillus found by us (C. A. and R. B.) in the two first cases which we published.

Coexistence of Different Infections in Epidemics.

Since 1900 the paratyphoid fevers have been under more or less general observation, often under the form of epidemics, and associated generally with an outbreak of Eberthian typhoid fever. They have been the subject of very numerous publications, and the present war has shown their extreme frequency. The researches made with the armies have considerably enriched our knowledge of the symptoms, the lesions, and the complications of these maladies, as well as of their etiology and pathogenic conditions. In this last connexion there is a point which has given place to particularly interesting observations. Most generally the epidemics of paratyphoid fever coexist with an epidemic of Eberthian typhoid fever. But the proportional occurrence of these different infections varies in the mixed epidemics; it is often the Eberthian fever which has been found predominant, but sometimes the paratyphoid B fever, and sometimes even the paratyphoid A. It has been consequently asked if this coexistence does not result from the three infective germs ordinarily finding themselves united in the same infecting materials, such as drinking water or food contaminated with typhoid dejecta. Thus would be explained the phenomenon that from the same infecting source some acquire in a predominant fashion Eberth's bacillus, others the paratyphoid A or B bacilli. This hypothesis would account also for a series of curious observations.

Meslay and Coville[8] have seen a paratyphoid B fever in the father coincide with an Eberthian typhoid fever in the daughter. Several authors have observed in the same patient the succession of two of these infections: thus Jeanselme and Agasse-Lafont[9] have observed the Eberthian fever followed by paratyphoid fever; P. Courmont, Chattot and Pierret[10] have seen paratyphoid B fever followed by paratyphoid A; P. Hébert and M. Bloch[11] have found successively in the same patient first the *Bacillus paratyphoid B* and later Eberth's bacillus in the blood. In the same patient one can encounter in a localised point of the organism one of the three germs, while the general infection is produced by another. Thus, J. Minet[12] has seen the complication of pulmonary congestion provoked by paratyphoid B in an Eberthian subject and by the paratyphoid A in a patient suffering from paratyphoid B fever.

It is true that in certain circumscribed epidemics only one germ has been found. Recently P. Hébert and M. Bloch[13] have observed several of these little monomicrobic epidemics. For example, in one company of a regiment out of 45 patients in the period of one fortnight these observers obtained 37 positive hæmocultures, all giving paratyphoid A exclusively; in another company in three weeks out of 12 patients they obtained, in 9 positive hæmocultures, Eberth's bacillus alone.

Hypothesis of Typhoidic Infection with Multiple Germs.

But these facts are in no wise irreconcilable with the hypothesis of the habitual coexistence of three typhoidic germs in important epidemics. It is necessary, in fact, to note that, one of the germs having infected a patient in a predominant way, he disseminates this germ alone, and becomes a point of departure of a little monomicrobic outbreak in the middle of a great polymicrobic epidemic.

The hypothesis of typhoidic infection with multiple germs furnishes also the explanation of certain results, adjudged irregular or paradoxical, of the sero-diagnostic test. In some cases the hæmoculture has been seen to give, for example, Eberth's bacillus alone, while at the same time the serum possessed agglutinating properties, especially for a paratyphoid. If the hypothesis of the duality of these infecting germs is admitted, it can be conceived that at the moment at which the Eberthian septicæmia was existing, the paratyphoid agglutinin was already developed. Thus Grimberg[14] explains in this manner a case in which serum diagnosis led to the belief of an association of Eberth's bacillus and of paratyphoid B., and where the hæmoculture had given Eberth's bacillus and paratyphoid A. The explanation is that the three infections followed in the following order: paratyphoid B, Eberth's bacillus, paratyphoid A.

Thus it is essential, in order to give to the sero-diagnostic test all its value, to measure the agglutinin, to separate by the methods of saturation the multiple agglutinins in case of mixture, and to follow, in short, in the course of the illness the successive variations of the curve of these agglutinins.

Hæmoculture.

In the same way with hæmoculture, it is advisable to take special precautions to discover not one germ only, but those which may be associated with it, and which the usual procedure would not allow of distinguishing. In truth the worker is never sure of recovering from the blood several germs in case of mixed infection, because the phase of septicæmia for each of them is limited, while it seems often to be even shorter in the paratyphoid infections than in the Eberthian infections. But it is possible, when the microbic association exists in the blood, to put it in evidence by certain procedures indicated by Grimberg. For sowing the blood, tubes in V can be used containing bouillon and a little fine sand; the blood is deposited in one of the branches of a tube, and after being in the incubator the most mobile microbe of those developed will be the first to pass into the other branch of the tube, after passing through the sand. Care is taken in this procedure to add in the branch which is sown some serum possessing strongly agglutinating influence for two of the three germs, so as to immobilise them and to prevent them from traversing the sand. By operating on several tubes with different serums isolation can be obtained of the different germs of a mixed infection.

[14] A. Grimberg: Les Fièvres Typhoïdes ntriquées, Thèse de Paris, 1916, No. 115.

With this question of hæmoculture in case of associated germs is connected that of the reaction furnished by mixed cultures where we are dealing, for example, with two of the germs in unequal proportions.

In provoking in a subject a double septicæmia by intravenous or intraperitoneal inoculations of a mixture of Eberth's bacillus and of paratyphoid B, in the proportion of one of the latter to four of the former, I have been able to ascertain that the hæmoculture carried out in the ordinary way and without the special precautions indicated above shows always the *Bacillus paratyphoid B* recognised by its characteristic reactions in the classic media—slow decolouration of neutral red and formation of gas in glucose bouillon.[15] In making the culture mixtures, Grimberg has found that with one drop of culture of one of the germs for 25 of another it is the reaction of the predominant microbe that is found on sowing the mixture in different media.

P. Hébert and M. Bloch[16] have demonstrated that at the end of four days in the mixture of Eberth and paratyphoid B it is necessary that the latter should not exceed the proportion of 1 : 1,000,000,000 if Eberth's bacillus is to preserve its characteristics pure. The paratyphoid B shows itself the most resistant and Eberth's bacillus the least.

Practically, it can be held from these researches that when the usual technique of hæmoculture reveals the *Bacillus paratyphoid B* the possible coexistence of an Eberthian infection cannot by that fact alone be rejected. Thus, it would not be right to neglect to associate with hæmoculture the investigations of the agglutinin in the serum of the patient.

Some Practical Results Arising from the Hypothesis.

Certain consequences of a practical nature, and relative to vaccination, result from the hypothesis of the frequent coexistence of the three germs in the infected material. It is known that for a long time antityphoid vaccination was only carried out by means of vaccines prepared with Eberth's bacillus alone. Now this bacillus does not immunise against the paratyphoid bacilli and vice versâ. Thus, during the first period of the war while the frequency in our armies of Eberthian typhoid was greatly diminished owing to preventive inoculation, the paratyphoid fevers have in no wise been diminished; on the contrary, these have multiplied in a manner as unusual as unforeseen, taking the place to some extent of Eberthian typhoid. On this subject curious statistics have been published. Marcel Labbé,[17] among others, has dealt in the same sanitary organisation, and during eight months, with the statistics of the patients attacked with typhoid and paratyphoid fevers, noting if they had or had not been vaccinated with Eberthian vaccine. He ascertained that the curve of the non-vaccinated patient was very exactly parallel to that of the cases of Eberthian typhoid fever, which can be easily understood, but also—and this is a fact paradoxical in appearance and at least unexpected—he found that the curve of the vaccinated patients remained no less exactly parallel to that of the patients with paratyphoid fevers. These two last curves rose, moreover, in measure as the Eberthian typhoid fever diminished, as though the anti-Eberthian vaccination in protecting the subjects against typhoid fever had predisposed them to the paratyphoids. One could not see the reason for such a predisposition, but the anti-Eberthian vaccination had not suppressed the causes of typho-paratyphoidic infection, while among the subjects who had become refractory to Eberth's bacillus it was the paratyphoid infections which alone developed.

This recrudescence of the paratyphoid fevers, occurring with the diminution of the Eberthian fever obtained by vaccination, was one of the first reasons to suggest the hypothesis of the ordinary coexistence of the three infecting germs.[18] It remains one of the arguments most important in its favour. There follows from it in addition this capital conclusion in practice. It is that the preventive vaccinations should be made with a mixed vaccine, a trivalent vaccine. Moreover, the application of such a vaccine has given, since it has become general, complete satisfaction in reducing to almost nothing Eberthian typhoid fever, and the paratyphoid fevers altogether.

Another practical conclusion can be added. It is that curative vaccination should be carried out with a trivalent vaccine, since the typhoid infection may be mixed, and this mixed nature of the illness is not always easy to put in evidence for the clinician.

POST-TYPHOID ATONY OF THE CÆCUM.

By MAURICE LOEPER,
PROFESSOR IN THE FACULTY OF MEDICINE AND PHYSICIAN TO THE HOSPITALS, PARIS.

Intestinal troubles count among the best-known sequels of typhoid infection. The explanation of their frequency is to be found at once in the localisation of the infective process in the intestinal mucosa as a result of the action of Eberth's bacillus or other members of the typhoid group, a localisation not only specific but deep and extensive.

These intestinal complications may be regarded for practical purposes as three—namely, diarrhœa, mucorrhœa, and constipation—being the three usual forms of intestinal reaction to chronic irritation. They are further complicated by the possible production of febrile or painful crises which are apt to be mistaken for acute infections on the one hand or for appendicitis on the other. They originate from a colitis—sometimes discrete, sometimes extensive—and most often from a selective inflammation of the cæcum. The cæcal localisation constitutes in itself a complication, and a very persistent complication, of the enteric fevers. To it alone is often due the diarrhœa, constipation, or mucorrhœa. Clinically it is accompanied by gurgling. To X rays it is revealed by dilatation.

The condition is well described by the word typhlatony, but it is not the typhlatony of Fischer which is an inflammatory infection, congenital or mechanical in origin. It is rather an atony in which lesions of both mucosa and underlying muscularis play a part, as in certain forms of gastric dilatation secondary to infective gastritis. I propose to show in the following the frequency of typhlatony as a sequel of enteric maladies, and to study the clinical and anatomical characters of this affection, giving as precisely as I can the treatment, immediate and remote.

Symptomatology.

It is in the early weeks following an attack of typhoid, sometimes immediately after the temperature has fallen, sometimes on resuming solid food, that the first symptoms of cæcal atony arise. The most important is without doubt *diarrhœa*; it would be more exact to say liquid or semi-liquid action—hardly ever frothy—and rarely of any great frequency. It generally comes on in the morning, in the majority of cases soon after a meal, under the recognised influence, to which I have called attention elsewhere,[1] of the gastro-colic reflex on the irritable intestine.

Chemical examination shows a little mucus, rarely bile, and sometimes albumin, the latter an index of intestinal inflammation. Blood is nearly always absent, neither histological nor chemical tests revealing it. Alimentary residues are inconsiderable: the total amount of undigested fat does not exceed the normal; that of albumin and carbohydrate is larger and the two run parallel. The bacterial flora, which I have recently studied, shows fairly often a predominance of proteolytic bacilli, the presence of which explains the fœtor of the stools.

The diarrhœa is often followed by constipation and the coprostatic phase succeeds the diarrhœic, as is the rule in colic affections. But this constipation gives place every four or five days to the crises presently to be described. As for the mucorrhœa, it synchronises with one or another of these periods, but may exist alone. The stool may be glairy or frankly mucoid, the mucus occurring in flakes or little pellets and not in sheets, as in the extensive colic lesions. Mucorrhœa betrays the presence of cæcal irritation, microscopical examination then showing epithelial elements surrounded by mucus, polymorphonuclear leucocytes in fair number, eosinophiles, and even eosinophiles with polymorph nucleus.

Diarrhœa, constipation, and mucorrhœa alike are nearly painless; cæcal pain may, it is true, occur in the course of digestion and precede action of the bowels, which relieves it again. Pain in the sense of cramp or expulsive pain denotes an extension to the colon of the inflammatory process, and tenesmus implies extension to the rectum.

[1] M. Loeper: Leçons de Pathologie Digestive, third series; Paris: Masson éditeur, 1914.

On palpation of these patients there is found in the right iliac fossa a soft or slightly resistant cæcum which gurgles or sometimes even splashes. This *splashing* may be so marked as greatly to resemble gastric succussion, and when the stomach is much dilated and exposed confusion may arise. Radioscopy shows a distended cæcum generally very mobile, nearly always lying oblique and curved in upon itself, palpation under the screen showing that the contents are readily reduced or pressed back.

As a rule, the other segments of the intestinal tract are contracted and sharply convoluted, giving under the screen a fern-like appearance and allowing a bismuth meal to pass with difficulty. I lay no emphasis on the general condition, although urobilinuria, indicanuria, reduced arterial tension, and sometimes anæmia are the rule in these cæcal conditions. They are evidence of a hæmolysis on which I have insisted.

One of the most interesting features of the clinical course of typhlatony is its interruption by three kinds of crises which may mislead the diagnostician. These consist either in pain or in fever, usually following upon more or less pronounced periods of constipation, although this association is not absolute, and I have seen them make their appearance after an obstinate diarrhœa or a persistent mucorrhœa. Pain comes on suddenly and is characterised by a distressing sensation of tension with localised ballooning, with nausea, and even vomiting. It is rather a matter of a painful zone than of a painful point; confusion is possible with appendicitis, and I am satisfied that I have twice seen in the course of operations that *post-typhoid appendicitis is often nothing but a typhoid crisis.* The crisis lasts three days with febrile movement; it reaches a maximum on the second or third day, yielding then to a calming regime with compresses. The region remains sensitive, the calm persists for a variable time, a new crisis occurring after two or three months or even sooner. Apart from the character of the pain and the intestinal antecedents, the repetition of these crises alone would suffice to differentiate from appendicitis.

There sometimes also occur marked *febrile* movements: the temperature rises without apparent cause to 39° C. or above, the complexion becomes yellow, the urine contains an unusual proportion of indican along with much urobilin, the breath is short, and the pulse feeble. The condition suggests an acute incident. But it is, in fact, a cæcal crisis; the cæcum is more sensitive, the colon more contracted, the stools more fœtid. After a matter of 2–4 days, with the help of Vichy water, bismuth, and gentle laxatives, everything settles down again.

Morbid Anatomy.

It would have been difficult enough to assign lesions to these symptoms and critical exacerbations, but good fortune gave me the opportunity of studying them in an operation case.

A young man, 20 years of age, who suffered from typhoid six months previously, had three crises in succession which were wrongly attributed to appendicitis. We made with M. Du a diagnosis of typhlatony and advised laparotomy. We expected to find (we must confess) a congenital malformation or adhesions, but discovered instead an exceedingly marked inflammatory typhlatony, which was dealt with not by suture but by cæcal resection with cæcolostomy.

The enormous cæcum measured 9 cm. in diameter. Some whitish patches on its external surface, the wall thinned and almost transparent. A healthy appendix, no adhesions. On opening the cæcum, mucosa red, with linear ecchymoses, surface irregularly depressed without ulceration but presenting numerous very prominent follicles.

On microscopic examination two varieties of lesion of different age were recognised, one quite recent. There were seen ecchymoses, hæmorrhagic spots and striæ; vascular dilatations and numberless ulcerations not visible to the naked eye. The ulcers were superficial cutting off the ridges and not extending into the submucosa; fairly abundant collections of polymorphonuclear leucocytes were seen beneath the ulcerated zone and penetrating into the submucosa.

The older lesions may be briefly summarised as follows:—

1. In the non-ulcerated zones, glandular crypts in some places almost flush with the mucosa; in other places branching glands evidently multiplied; epithelium generally calciform with abundant production of mucus. Some zones in which the thickened prominent submucosa raises the mucous coat into papilla-like proliferations.

2. Pronounced folliculitis characterised by exuberant follicles forming by continuity a single layer. The larger proportion of cellular elements in the nature of lymphocytes, fairly numerous eosinophiles. Some cells with polymorph nucleus give evidence of acute irritation.

3. The connective tissue layer thickened in some places, thinned in others.

4. Finally, the muscularis much reduced, islets of nerve cells surrounded by marked connective tissue proliferation.

In a word, the lesions show evidence of an old fibrous and atrophic reaction on which an acute process had been grafted.

Relation of Primary and Secondary Lesions.

It is a far cry from these residual lesions to those which can have been produced under the influence of the primary disease. The latter, well known in typhoid, where their intensity merits the term colo- or typhlo-typhoid, have been well studied by M. Rathéry[2] in paratyphoid B. They range from intense folliculitis with ulceration at the summit to extensive ulcerations with or without perforation, and even to spreading, almost vegetating, proliferations. It is possible, however, to see in these primary lesions the remote cause of the secondary lesions.

Etiology.

The frequency of cæcal atony as a sequel to the enteric fevers is in my statistics shown to be about 65 per cent. I can go further in regard to its origin and say that in nearly 60 per cent. typhoid or paratyphoid is found. I should imagine that paratyphoid more frequently gives rise to it. In fact, mucous or dysenteric colitis is the result more of para. B than of Eberth, and the post-mortem lesions of para. B are more intense, more extensive, and more strictly cæcal than those of Eberth.

In the production of cæcal atony the question may be asked: Are the inflammatory lesions alone to blame, or is a rôle to be ascribed to bacterial toxins and to their action on the muscular fibres? The latter hypothesis is probable, but it is only a hypothesis which need not therefore delay us long now.

Treatment, Medical and Surgical.

The therapeutics of cæcal atony are both medical and surgical.

Medically, it consists in a dressing for the large intestine, realised by a dose of 3 g. of bismuth half an hour before each meal and collargol 0·1 to 0·15 g. daily. Lavage with collargol or bicarbonate of soda, suppositories of ichthyol and tannin, with or without belladonna or Indian hemp, may have a topical effect, at the same time analgesic and antispasmodic. The diet should be principally milk and farinaceous, while lactic ferments, by diminishing the putrid fermentation, may retard or ward off the acute accidents. The cure at Chatelguyon and that at Plombières are specially efficacious. In the febrile or pseudo-appendicular crises I should recommend ice locally, a diet of vegetable broth or solution of lactose, and gentle purgation with divided doses of sulphate of soda.

But there are cases where medical treatment alone is insufficient. The surgeon can and should intervene when the crises recur, and when they take on a character of special gravity or of disquieting chronicity. Interference should be directed towards the mechanical as well as the inflammatory phenomena—the atony and the typhlitis.

Cæcostomy or appendicostomy, it must be admitted, allows of a more complete disinfection, but they do not reduce the cæcal cavity. Suture of the cæcum diminishes the stagnation but only combats the typhlitis indirectly, and the latter is more the cause than the consequence. These diverse operations certainly do not seem to give durable results and should yield to the ileo-, colo-, or sigmoido-stomy with resection of the cæcum and of a larger or smaller part of the ascending and transverse colon. In this way the intestine is relieved of a dead weight, the organism no longer runs the risk of toxic absorption and of an infectious movement which always threatens.

Such measures are applicable, and indeed only applicable, to severe cases. In the two patients whom I have already mentioned they have given a good and permanent result.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 21, 1918.

The Voluntary Hospitals and the Ministry of Health.[1]

THE Council of the British Hospitals Association have circulated in the form of a pamphlet a clear and well-arranged statement with reference to the future relations of the voluntary hospitals to the Ministry of Health which will presumably soon be erected, though the difficulties attendant upon drafting the measure so that it should start safe from grave contention are being realised. The statement of the Association details the arguments for believing that the voluntary hospitals should remain on their present basis, one from which they administer directly to medical needs the charity supplied by those who can afford to give; but at the same time many large and concrete suggestions are put forward for the improvement of the manner in which the benefits of the voluntary hospitals reach the classes for whom they are intended. While, on the one hand, the statement supports with force and logic the continuance of the principles upon which the voluntary hospitals exist and are worked, on the other, if only by the directions in which reforms and modifications are suggested, it admits that at the present moment there is in the working of the voluntary hospitals lack of economy in many important directions. This lack of economy is chiefly shown by the employment of the benefits of the hospitals for the relief of diseases, disorders, and injuries which in no sense require the highly specialised and scientific treatment which the ideal voluntary hospital should afford. The views of the statement are put forward in the name of Mr. J. COURTNEY BUCHANAN, secretary and house governor of the Metropolitan Hospital and honorary secretary of the British Hospitals Association. They have not as yet been formally considered by the Council, but it is thought that the pamphlet may usefully be taken as the basis for a discussion on the subject by the Association. A conference will therefore be held on Friday, Oct. 18th, at 3 P.M., at St. Thomas's Hospital, London, and the committees of the institutions which constitute the Association have been invited to send to the honorary secretaries, at 14, Victoria-street, Westminster, S.W., any suggestions which they think might well occupy the attention of the meeting. An invitation has also been extended to hospitals which are not represented on the Association that they should indicate to the honorary secretaries of the Association the names of those by whom they would like to be represented.

It is understood that the Bill setting up the Ministry of Health as at present drafted does not affect, at any rate directly, the voluntary system of hospital support and administration. Indeed, the Council of the British Hospitals Association have received from Dr. ADDISON an implied assurance to this effect. But no one can conceive any Bill erecting a Ministry of Health whose provisions will not in many directions have an influence on the working of the voluntary hospitals. Mr. BUCHANAN asks pertinent questions as to what classes or sections of the population it is proposed "to bring into the net of the Public Health Service," and throughout the whole of his pamphlet he is clearly of opinion that a connecting link will be required between the voluntary hospitals and the various State-subsidised, or rate-supported, or public-assistance institutions, all of which will of course play their part in the scheme of the new bureau. Again, it is evident that the Bill must further affect the revenues of the voluntary hospitals, which are already in many cases precarious. There is sure to be a decline in the subscriptions and donations of the heavily taxed classes, who have hitherto been the chief support of the voluntary hospitals; and if larger and more regular subsidies are to be obtained in small subscriptions from the working classes arrangements will have to be made for giving these subscribers or their nominees a direct share in the management of the hospitals. This in some of the institutions concerned has already been done, but in many others a move in this direction will be tantamount to a fundamental alteration in the management of the charities. The prospect of more direct representation of popular views on hospital boards is one which we not only view without any apprehension, but which we welcome as certain to lead to an intelligent appreciation on the part of the public of the vast part played for national good by the institutions, alike as centres of medical treatment, nurseries of medical education, and foci of medical progress. The majority of the attacks upon voluntary hospitals are inspired by ignorance, and those who make them will lose their audience when the public learn directly what are the scope and administrative arrangements of the charities. It is to facilitate consideration of these and similar important questions that Mr. BUCHANAN has set out a series of definite propositions in terms which can be discussed. Under these propositions, and others that may yet be put down for debate, the authorities of the voluntary hospitals will be able to define the position which they wish to fill, and which they think they can adequately fill, in relation to the Ministry of Health.

The propositions commence with the thesis that the voluntary hospital system should be retained in this country, and a definition follows of the functions which the voluntary hospitals should discharge if they are to make out a good case for permanency. Voluntary hospitals, it is suggested, should be such medical, surgical, and nursing schools as can supply treatment "made in every respect as perfect as possible in hospitals equipped and maintained in all their special and general departments in the highest state of efficiency and adapted to the requirements

[1] Statement on the Voluntary Hospitals and the Proposed Ministry of Health Bill, by J. Courtney Buchanan. British Hospitals Association, 14, Victoria-street, S.W., and the Scientific Press, Ltd. 6*d*.

of the latest medical, surgical, and nursing science and education." This high standard of hospital treatment, it is indicated, can be arrived at in two ways, working simultaneously, the first within the hospital and the second without its walls. Within the hospital every step must be taken to keep the institution in the van of bacteriological, pathological, and scientific research, while raising wherever possible the common pattern of nursing and medical education. Without the hospital, popular appreciation of what the institution stands for will elevate the clinical practice. Trivial cases should in this way be eliminated from hospital care, and only those patients be sent to the hospital whose plight is suitable on the ground of its serious nature, its unusual manifestations, or the necessity for treatment which is only at the disposal of a large and well-equipped institution. For the public will see that the hospital should be their consultant authority not their domestic doctor.

Remedial Gymnastics.

REMEDIAL gymnastics, including massage and electrical therapeutics, have obtained a definite place in the practice of medicine, and one that is growing daily in importance by reason of the injuries and mutilations of war. At the various great centres for relief of disablements investigation into the principles of these methods is forming a sound basis for their application. But much depends on the instruments through which the treatment is applied, and the traditional instrument in this country, the Swedish masseur, is not of constant quality. To those who have the necessary experience and knowledge it must have become evident that the Swedish masseur, as we meet him in practice, can be placed in one of two groups. Those in the first are serious and unostentatious in mien, anxious for medical help and advice, delicate in their treatment—in short, a good type of physico-therapeutical expert. The second group comprises persons, self-possessed and self-sufficient, who seek out medical men, not to solicit help or advice, but as a means of securing employment, and of using well-known names in specious advertisement. Their work is often characterised by a lack of finish, sometimes by a roughness amounting almost to brutality, which bespeak bad training and lack of experience, and their business outlook is not one which is likely to be shared by medical men.

Dr. EMIL KLEEN, the translation of whose monograph on Medical Gymnastics we review this week, has greatly enlightened us as to the reason for the existence of these two classes of Swedish masseurs. Unless things have greatly changed since Dr. KLEEN'S book was published in Swedish in 1911, many of these experts may rarely, if ever, have treated a patient at all in their own country before being let loose upon us. The ignorance of our own medical men as a whole of physico-therapeutical work has enabled self-advertisement to be its own reward, with the result that good and bad masseurs alike have flourished; in fact, there is reason to fear that the inferior grade has obtained the better positions. In the face of this dangerous competition the Incorporated Society of Trained Masseuses has struggled for a quarter of a century, and has been successful in raising to a high level the standard of massage in this country. But the maintenance of this standard has been rendered additionally difficult by the presence of many foreigners, and among them of certain persons from Sweden, who, according to their own distinguished countryman, are not masseurs but quacks. It is hoped that amalgamation between the Incorporated Society of Trained Masseuses and the Institute of Massage and Remedial Gymnastics in Manchester will help to solve the difficulties ahead. A charter, for which application has been made to the Board of Trade, should protect the title of masseur from fraudulent usurpation, and while the council of the new amalgamation should be empowered to coöpt as members all those who can produce satisfactory evidence of training in recognised schools abroad, they must take steps to examine those whose training appears deficient. Only thus can the public be protected from the danger of the uninstructed dabbler in remedial gymnastics, while the elimination of the quack will be in the interest of all genuine Swedish masseurs. Assuming that what Dr. KLEEN tells us is still true, it is essentially unfair for us to accept the pretender on an equal footing with the well-trained, experienced, and capable gymnastic director.

The French Supplement to "The Lancet."

WE publish this week the first of a series of Supplements which will reach us under the editorial direction of Professor CHARLES ACHARD, Professor of Pathology and Therapeutics in the University of Paris, and Major CHARLES FLANDIN, D.S.O., Chef de Clinique à la Faculté de Paris. In the brief statement prefixed to the Supplement by our editorial colleagues the aim which we have before us is succinctly stated. The Supplements are intended "to enable British doctors to understand the theories and researches of French doctors," and Professor ACHARD and Major FLANDIN propose to make good the promise in a very practical manner. For the Supplements will be shaped to include a general review of some big medical subject and an original article dealing with a particular question: in the general review the theoretical side of medicine will be more apparent as the various lines of medical thought and medical practice are collated, while the original article will be invited from actual workers, the medical author describing for us his personal researches.

We have decided to make this departure during the war and at a time when the shortage of labour and paper compel us to limit the scope of the endeavour. The hope of our French colleagues and of ourselves is that what we supply now, while proving useful at the time, will be accepted by our readers as a promise of larger things in the brighter future we are now approaching. The close understanding between our Allies and ourselves, which has developed during the war in every province of statesmanship, every naval and military proceeding, and in many details of political economy, is showing itself in the growing coöperation in medical theory and practice. The union will, as our colleagues say, exist after the war in all fields of human activity, and in none is it more important for the human race that mutual comprehension should be perfected than in the grand field of medicine.

Annotations.

"Ne quid nimis."

THE FUTURE OF THE DISABLED MAN.

THE future is always an unknown quantity, and for most of us the war has made this fact more obvious, whether we treat it in the spirit of adventure or of anxious foreboding. But there is one class of the community to whom our sense of justice, if nothing else, wishes to guarantee a future, whatever else may stand or fall, and that is the man who has been permanently disabled in mind or body by service for his country. Much sentiment has been poured out, largely in the form of light literature and cigarettes, and a special Government department created, but the reinstatement of the disabled ex-Service man is an enormous undertaking which is doomed to failure unless it commands the active support and interest of every industry in the country and of all the organisations dealing with employment. The successful solution also assumes the proper orientation when the average citizen considers the problem as a whole, as well as his own personal relation to it. The launching this month of the King's Fund for the Disabled has served to focus public attention on the subject, and two magazines of which the first numbers are before us should serve to instruct. *Réveille* is the successor of *Recalled to Life*, of which three informing numbers appeared under the editorship of Lord Charnwood. Mr. John Galsworthy now becomes editor, and the publication is undertaken quarterly by H.M. Stationery Office at 2*s*. 6*d*. Articles appear on the treatment and training of disabled soldiers by Mr. Hodge, Sir John Collie, Sir Robert Jones, King Manoel, Major Robert Mitchell, and others, and contributions by well-known authors and artists attract the general reader. The *Ex-Service Man* is published fortnightly, the half-yearly subscription being 8*s*., and is described as an independent journal for those who have served. The editor, Captain H. H. C. Baird, D.S.O., makes it clear that he represents no sectional interest whatever, and that his columns will be open to free expression of every shade of opinion. The first impression of *Réveille* was almost immediately sold out; we wish a similar success to the *Ex-Service Man*.

THE OCCURRENCE OF RABIES IN ENGLAND.

THE recent reported occurrence of canine rabies in Devonshire emphasises the necessity for maintaining a rigid observance of the regulations with respect to the quarantining of all dogs arriving from abroad before they are admitted into this country. The outbreak in the Plymouth district is probably connected with the present prevalence in France of canine rabies, which has existed there during the past two years, particularly in the department of the Seine. During 1917 some 47 cases of rabies were verified in Paris and its suburbs. In one instance an infected dog is stated to have bitten no fewer than 11 persons in a restaurant to which it had gained admittance. It is believed that this recrudescence of rabies in France is due to some extent to the persistent neglect of the police regulations concerning dogs and especially to the omission to muzzle these animals. The danger has been increased in the department of the Seine by the presence of numerous vagabond dogs under no control. Dogs are sometimes taken from the urban districts by their owners in the holidays into the country districts where they are allowed to run free and unmuzzled, and where they are liable to come in contact with strange dogs, afterwards on their return home developing rabies. French soldiers on leave from the front occasionally bring their pet dogs along with them, and some of these animals get lost in Paris, and some, indeed, are intentionally abandoned there by their owners. Similar occurrences are said to be not unknown in England, while our soldiers on leave have occasionally attempted to smuggle their dogs ashore at the Channel ports in defiance of the regulations. It is reported that more than one airman has brought his dog with him from France to England on an aeroplane. Whether these allegations are well founded or not, it is, in our opinion, not improbable that the Plymouth outbreak of canine rabies may have been due to the surreptitious and unlawful introduction into this country of a dog that had contracted the disease in France, and which after its arrival developed the malady. The authorities in Devonshire and Cornwall, as indicated in our last issue, are taking all necessary precautions, and the passage of dogs from Devonshire and Cornwall to any other part of England has been forbidden. A case, now reported from the Isle of Man, will surely lead to similar precautions.

"FOOD AND HOW TO SAVE IT."

WE have received from the Ministry of Food a copy of the revised (third) edition of "Food and How to Save it" by Dr. Edmund I. Spriggs. While modestly described as "this little book" by its author the subject with which it deals is of extraordinary importance. The publication in 1917 of these plain physiological facts in relation to food economy and food sufficiency materially helped the nation to face a critical situation. We believe that the system of food control now in being has worked smoothly, and while it has entailed many hardships here and there none of them have been tragic or intolerable. The spirit in which the public received food control has been altogether admirable, and little sacrifices have successfully and permanently kept off a threatened disaster. The supplies, indeed, have improved since the first restrictions were imposed upon us, with the result that few think it necessary when from home to take coupons with them. This reflects the highest possible credit upon the scientific authorities, producers, shippers, and others who were responsible for advising our administrators upon this great question. In the third edition of this book the extension of compulsory rationing to include meat, fats, and some other foods as well as sugar has made it necessary to recast the diets and make other alterations. A chapter has also been added on meatless dinners. Dr. Spriggs has had the advantage of the assistance of the Scientific Adviser to the Ministry of Food, Professor Starling, in its preparation. The chapters are clearly arranged in logical sequence and written in simple terms, which, while scientifically sound, should easily be "understanded of the people." We are informed that a limited number of copies are available (gratis) for public speakers and others interested if they apply to the Ministry of Food (Room 605), Palace Chambers, Westminster, S.W. 1.

With reference to food problems generally, the June number of *American Medicine* deals extensively with dietetic questions, and among the many

expert contributors it is gratifying to our sense of national self-respect that so many English writers have been asked to join in the symposium. From the moment that Germany realised that the war would be long, she called upon her most distinguished men of science to work at the problem of food supply and to ascertain the minimum supply compatible with health. Incidentally it may be stated that these inquiries have thrown much light on various dietetic obscurities. In this country we have greatly neglected the whole question of the physiological requirements, although we have solved, perhaps better than any other nation, the problem of the supply. It will require a sharp educational effort and much patient propaganda work to shake John Bull in his faith in the British breakfast-table and his extravagant ideas with regard to the virtues of roast meat. No nation in the world is so uneconomical in dietetic habits as the British. Valuable information is to be derived from reading the "Food Number" of *American Medicine*, and among many good articles we call particular attention, from the point of view of the importance of the subject-matter, to the following: The Fetish of White Flour, by Dr. H. W. Wiley; Place of Milk and Vegetables in the Diet, by Dr. H. C. Sherman; Milk-butter, Fats, Nut-butter, and Oleomargarine for the Child, by Dr. George Dow Scott; the Vitamines or Accessory Factors in Relation to Dietary Problems arising from the War, by Dr. A. Bruce McCallum; and Method of Changing and Reforming the Intestinal Flora, by Dr. J. H. Kellogg. Running throughout the majority of these articles, as well as through the large number of smaller editorial and unsigned paragraphs, are two fundamental and paramount ideas: one the need for reform in respect to our ideas of the value of animal food, and, secondly, the important part which the vitamines and other accessory food elements play in the maintenance of nutrition. One author after another emphasises the point that in order that a diet may be adequate for the maintenance of health in either a grown or growing individual both a fat soluble accessory body (A) and a water soluble accessory body (B) must be present in sufficient amount, or the symptoms of malnutrition are likely to supervene. Very interesting illustrations of insufficiency diseases resulting from war conditions in Glasgow, Kut, Mesopotamia, and other localities are given by Professor McCallum in his article on the vitamines. The most interesting feature of these results of vitamine starvation is furnished by the outbreaks of xerophthalmia among children in the enemy countries, for these have been referred to lack of the fat soluble accessory body (A) shortage of animal fats having led to the substitution of vegetable oils. The increasing use of these oils in this country, and the high price of butter and other animal fats, may possibly give rise to similar unfortunate experiences among our own population unless attention leads to prevention. Special attention is directed to Dr. Kellogg's paper on the changing of the intestinal flora. In this the author insists very strongly on the importance of supplying to the colon the carbohydrate necessary for promoting the development of acid-forming bacteria. Lactose is the most slowly absorbed of the sugars, and is therefore indicated in cases of alkaline stools and symptoms of intestinal toxæmias. Uncooked starch is also recommended for the same purpose—a suggestion which provide the clue to the old wife's practice of giving arrowroot and water as a cure for diarrhœa in infants, a method of treatment which has of recent years fallen into disuse, but which, after all, may have a rational basis. *American Medicine* has certainly performed a service to the medical profession, and consequently to the public, in collecting under one cover so many valuable and up-to-date contributions to the subject of scientific feeding.

THE ASYLUM STRIKES.

THE staffs of an English and of an Irish asylum recently fell victims to the insidious attacks of the strike epidemic. We are not in a position to judge accurately of the grievances in either case, whether relating to hours or wages. Differences of opinion between employer and employed upon these fundamental conditions led to the crisis, and the differences are being, or by this time have been, adjusted. But an expression of sympathy cannot be withheld from the medical officers of the institutions who found themselves in so critical a position owing to the desertion of their subordinates. At the English hospital we learn that 120 attendants and 150 nurses in immediate charge of some 2500 insane patients—some extremely violent and others painfully helpless—struck work without warning. The spirit of unionism amongst the rank and file of asylum service, whatever good lies behind it, seems here to show an over-development. The Asylum Workers' Union deals not with material products, the non-production of which may cause more or less inconvenience to the community, but with human lives, and those of the most pitiful kind, dependent upon unintermittent aid and care; and although the Union claims to have made some concessions to secure the "care of the worst cases," it is obvious that the abstraction on strike of some 258 members of an already attenuated staff cannot be regarded lightly. This union, established in 1910, should not be confused with the Asylum Workers' Association, founded in 1895 for the purpose of improving asylum nursing and elevating generally the aims and status of asylum workers.

AN ITALIAN VIEW OF ANGLO-SAXON MEDICAL JOURNALISM.

Dr. L. Verney contributes to *Il Policlinico* (Practical Section, June 23rd and July 14th) an interesting article on the medical periodicals of this country and the United States. For many years the medical profession in Italy almost ignored such publications, but it has come to recognise that in medicine the Anglo-Saxon races have reached a high position, and that views of that position derived from German sources are quite untrustworthy. He takes as types of weekly papers the *British Medical Journal*, *Journal of the American Medical Association*, the *New York Medical Record*, and THE LANCET. With regard to the addresses and scientific papers published in the columns of these journals he compares them favourably with their Italian counterparts. In conformity with the English character, the lecturers, he finds, tackle problems of practical interest, enriching them with their ripe experience and clinical acumen, selecting with unerring judgment the good and the new. While in the English journals a considerable space is devoted to clinical cases, "praiseworthy, but somewhat dull," the American doctors rather favour subjects of a more general type. For the editorials and

leading articles he has nothing but praise. Extremely interesting and showing full and accurate knowledge and rare critical balance, they may be considered the most useful portion of these journals, says Dr. Verney, who is particularly interested in the social aspect of medicine and crusades against quackery. He confesses that in Italy they have not yet felt the want of defending themselves against improper patent products, prejudicial alike to the public health and the medical interest. He draws attention to the fact that THE LANCET has for many years equipped a scientific laboratory for the analysis of medicines, foods, wines, &c., thus protecting the public against adulterations and frauds of every kind. He deplores the fact that abstracts are neglected in the two great English journals, and that foreign works are reviewed only to a trifling extent. In this respect he compares our journals unfavourably with those of America. It seems to him somewhat anomalous that in this country archives of clinical general medicine only exist in the form of the *Quarterly Journal of Medicine* and the *British Journal of Surgery*, and he finds the cause in the fact that the medical and surgical staffs of the hospitals give their services gratuitously, and do not feel called upon to undertake an exhaustive study of the clinical cases occurring in their hospital work. Moreover, the clinical professors do not succeed in forming satisfactory schools, as their assistants are appointed for too short a term, and hence are not sufficiently established in an academic career and with difficulty devote themselves to study. Dr. Verney is particularly impressed with the prominence given in English periodicals to tropical medicine, the outcome of work in British colonies. The general conclusion that Dr. Verney arrives at is that the most prominent characteristic of the Anglo-Saxon medical press is its practical tendency, and he prophesies an immense development in the near future, adding that the success of Anglo-Saxon medical journalism will be followed in Italy with growing sympathy.

THE SUPPLY AND ADJUSTMENT OF ARTIFICIAL LIMBS.

THE problem of the supply of artificial limbs has already aroused much attention and will remain as an outstanding feature of medical organisation for the care of pensioners. The number of men who have been fitted with limbs and who await fitting already runs into many thousands, and it is greatly to the credit of those who have organised Queen Mary's Hospital at Roehampton and the other limb-fitting hospitals that the supply has kept pace with the demand in such a way that the number of men who await their limbs is by no means excessive. When it is realised that the total number of artificial limbs made in England in one year before the war was probably less than the number of limbs now supplied in one month, we must acknowledge that we are greatly indebted to these organisations and to the American limb-fitting firms who have come to their assistance. But the fitting of the artificial limb is only the beginning. In almost every case an artificial leg requires readjustment within a few months from the time of its manufacture, a readjustment necessitated by alterations in the stump. And even this is not the end; second and subsequent readjustments are required, then repairs, and eventually replacement of the whole limb. This work of adjustment and repair is cumulative; it increases by leaps and bounds. At the present time the number of men returning to hospital for this purpose amounts to 50 per cent. of the total number of men who have been supplied with limbs up to date. As the men who have lost their limbs are for the most part young, this condition of affairs may be expected to continue for many years. The readjustments and repairs require a large and elaborate organisation. Haphazard orders that men whose limbs are unsatisfactory are to report to their local War Pensions Committee, be seen by the medical referee, and have the repairs done by the local limb-maker will not do. Very few medical men have sufficient experience of limb-fitting, and it is to be feared that many instrument-makers who describe themselves as limb-fitters have no real experience of the work. The results are already to be seen in the complaints that appear in the press of the unsatisfactory nature of the limbs supplied. It may be confidently stated that on the whole the artificial legs that have been supplied to soldiers and sailors in this country are as good as any that can be obtained, and that in the first place the fitting of the limbs has been satisfactory. In almost every case if the limb becomes unsatisfactory it is because it no longer fits. Unfortunately, when such an ill-fitting limb comes before a medical man, he, being inexperienced in the work, may be led to believe that the limb has been wrongly designed and constructed, and he is sometimes supported in this belief by a local limb-maker, who cannot be acquitted of the desire for a condemnation of the original limb and an order for an entirely new one of his own make. It is to be feared that this trade interest has up to now entered to some extent into the reports upon limbs given by the small local makers. It is now generally acknowledged that the so-called American type of artificial leg introduced at Roehampton possesses a mechanical superiority over the older English type or tendon leg, and that only the problem of material for use in its construction remains. This being so, perhaps the time has come when a single pattern of artificial leg might be adopted and all makers obliged to conform to this. The question of discarding an ill-fitting limb and constructing a new one would disappear, for makers would have no excuse for prescribing a new one of the same pattern as the old one. The use of one standard type, allowing always for variations in the level of amputation, would simplify the problem of re-adjustment and repairs, but not solve it. Much would remain to be done, chiefly, however, in the direction of education. Certain members of the medical profession must educate themselves in the fitting of limbs, and local makers must be similarly instructed in the repairing of the standard type and in refitting the buckets. The men themselves must be educated to know that when the limb becomes unsatisfactory or uncomfortable it is because it no longer fits, and the public, and employers in particular, must be made to understand that re-adjustment of artificial limbs from time to time is essential. All this can best be carried out at the large limb-fitting hospitals, which should become centres of education in all that appertains to artificial limbs.

The problem of artificial arms is a different one. Many types of artificial arms have been designed with numerous hands and alternative appliances.

So far the results can only be described as mediocre. This must be ascribed to a failure on the part of the authorities to realise that the artificial arm is a tool, the use of which must be taught. To give a man an artificial arm and send him home a few days later is useless. Recently this has been recognised: a month's instruction in the use of the arm is now considered essential. Only when the men who have thus been educated leave hospital shall we have any real test of the utility of the present types of artificial arms.

THE LATE PROFESSOR FORLANINI.

IN these days, when death is so busy and civilisation so disturbed, the passing of many important figures in civil life is apt to go unnoticed for some time. Such has apparently been the case with an eminent foreign colleague, Professor Carlo Forlanini, director of the medical clinic of the Royal University at Pavia, where he is reported to have died in his seventy-first year. His fame, at first confined to Italy, but of late years international, is, of course, due to work on the treatment of consumption by artificial pneumothorax, of which method he was a pioneer. In 1907 he began to issue a review of publications upon this subject, which in 1914 developed into an international journal, most of which appeared in the four Congress languages. Unfortunately, after a few numbers the disturbing influence of the war made itself felt, although from the first the secretaryship had been in Italian Switzerland. The technique which Forlanini had been elaborating since the "eighties" is now, with the addition due to Brauer, almost universally followed, while the treatment with which his name is associated, if of limited scope, has been acknowledged as valuable by tuberculosis specialists all over the world.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Gassed Patients.

THE number of victims of enemy gas has become great, and the Under Secretary of the Service de Santé has reorganised completely the arrangements for their treatment in the sense of making it both more effective and more rapid. The therapy of gas cases is becoming better understood. As regards hyperite, which is the agent most frequently employed by the enemy, it is now known that if the victims can be douched within the first three hours, with lavage of the stomach and complete cleansing of the clothing, they are almost certain to recover. But the consecutive treatment of pulmonary and ocular complications is protracted. The need was felt of a mobile organisation to give at the close of a bombardment prompt aid at points where cases have occurred in great number, and of a special hospital service at the base to deal with all the cases evacuated after undergoing preliminary treatment up to complete recovery. The first object is attained by means of motor ambulances, a new model of which has recently been planned. Each consists of a lorry and a trailer. The lorry contains tent, portable flooring, douching apparatus, and other accessories. The trailer contains a stove to disinfect clothing. The whole installation can be set up in about a quarter of an hour. The routine is simple. Cases are received and undress in a part of the tent screened off from the douche. Their clothes are passed through the disinfector while the patients douche, and on returning they resume their clothes, which have been freed from all trace of hyperite. Each installation serves for the treatment of 100 men an hour. Forty men can be douched at a time, while the disinfector has a capacity of 40 complete equipments. Every combatant division is to be provided with one of these motor ambulances, and all the gassed cases thus treated are then to be evacuated to base hospitals in the rear, none remaining in the army zone. Numerous beds have been reserved in the Paris military hospitals in two sections, one to receive patients suffering chiefly from pulmonary symptoms, the other for burns of the skin, eyes, and mucous surfaces.

Cyanamide and Alcoholic Drinks.

The manufacture of cyanamide by passing nitrogen over glowing calcium carbide has developed greatly during the war. Workmen employed in this industry are liable to certain symptoms; some—entirely external—caused by the spraying of particles of quicklime, others due to intoxication by the cyanamide itself with symptoms of acute vasodilation. The workmen have noticed that these symptoms were particularly marked among those who, after work, partook of alcoholic beverages, even in small quantities. M. Langlois has now shown by experiments on dogs, placed for several hours a day in an atmosphere charged with cyanamide dust, that the introduction of alcohol either by the stomach or intravenous injection immediately produced lowering of the arterial pressure, in certain cases resulting in death. M. Langlois concludes that the use of alcoholic drinks should be formally prohibited among workmen in cyanamide factories, a suggestion which hardly needs medical authority in the proved circumstances.

Recurrent Hæmoptysis due to Gunshot Wounds of the Chest.

M. Courtois-Suffit, in a study of hæmoptysis among soldiers who have been shot through the chest, states that a large number of cases relapse. Since this relapse may occur after a long interval he warns medical men against the tendency to consider such symptoms as necessarily pointing to tuberculosis, whether or no of traumatic origin. Radioscopy and examination of sputum are essential in each such case to control the information elicited on auscultation, or misleading statements will appear in the patient's discharge sheet.

Sept. 14th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Municipal Hospitals in Western Canada.

THE "Municipal Hospitals" movement in Western Canada has attracted widespread attention, and has been much discussed in the various provincial legislatures in that part of the Dominion of Canada. Most important is the question of responsible control of the administration of the funds and the acquisition of institutions for which the taxpayer will have to pay. These are not necessarily free hospitals which some have supposed them to be. The Province of Alberta has committed itself to legislation providing for these public hospitals, built and administered by municipalities or groups of municipalities; and a unanimous sentiment exists in Alberta and Saskatchewan for these hospitals, but the question of fees remains unsettled. The municipal hospital will likely pave the way for free hospitals later on, and once the latter are established they will, no doubt, be permanent.

Child Mortality in Montreal.

Owing to the heavy infant mortality in Montreal during the present summer Dr. W. A. L. Styles, secretary of the Baby Welfare Committee, asked that investigation be made into the causes thereof. Dr. S. Boucher, the M.O.H., has furnished the following figures showing that the child mortality in that city has been gradually decreasing. These figures cover the periods in each year between Jan. 1st and July 15th: 1914, 2352 deaths under 5 years of age; 1915, 2425; 1916, 1883; 1917, 2231; 1918, 1820. In 1906 the 0–5 death-rate was 271 in 1000 births, while in 1917 it was 178 per 1000 births.

Control of Venereal Diseases.

Reporting under the Act.—Under the terms of the new Venereal Diseases Act in the Province of Ontario there were reported during the last two weeks in July to the provincial board of health the following: syphilis, 66 cases—no deaths; gonorrhœa, 103 cases—no deaths; chancroid, 3 cases—no deaths. Thirteen medical officers of health throughout the province reported no cases at all.

Treatment of syphilis at Toronto General Hospital.—In the July issue of the *Canadian Medical Association Journal* Dr. W. T. Williams reports as follows on 500 cases of syphilis treated by the intravenous method: "Of the 500 cases so far treated only about 29 per cent. have been early, while 71 per cent. have been in the later stages of the disease. We have managed to secure negative Wassermanns on only 70 of the cases—23 early and 47 in the later stages. Practically all of the late cases were given in addition mixed treatment of mercury and potassium iodide. Twenty-four cases had a return to positive Wassermann, 35 remained negative, while 11 of them passed from our control."

Ophthalmia neonatorum.—Regulations seeking to protect babies from sore eyes have been drawn up by the Ontario Board of Health and approved by the Governor in Council. By them it is provided that every physician in attendance at births shall immediately instil into the eyes of new-born infants a 1 per cent. solution of nitrate of silver or 40 per cent. argyrol. If the eyes become swollen, red, and inflamed within two weeks the case must be reported to the Board of Health. The solutions are provided free by the Board of Health.

Sphagnum Moss for Surgical Dressings.

In 1916 the McGill University Women's Union established a sphagnum department in a laboratory placed at their disposal by the medical department of the University. Professor C. A. Porter was the first to initiate the work on this side of the Atlantic. He explored the bogs of Eastern Nova Scotia and secured specimens said to be perfect. The first of these dressings sent overseas were made up by the Junior Red Cross, Guysboro, N.S. The late Mr. Harry James Smith, of New York City, spent much time with Professor Porter and organised a plant at his own expense at Arichat, Cape Breton. The Canadian Red Cross is preparing an immense output for use in their own and French hospitals. Vancouver Island moss was also brought East by Mr. Smith at his own expense, which proved so satisfactory that he went last March to Seattle, U.S.A., to organise the industry in the North-western States and to look into the situation in British Columbia. Mr. Smith met his death in a railway accident while journeying West for moss for the Canadian Red Cross. The American Red Cross were greatly encouraged by his success and formed a department which was placed under Dr. J. A. Hartwell, of New York, as technical controller.

New Dean of Laval University, Montreal.

Owing to the death of Dr. E. P. Lachapelle, who was for many years a prominent physician in the Province of Quebec, the medical faculty of Laval University, Montreal, has elected a new dean in the person of Dr. L. de L. Harwood.

Toronto, August 15th.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

Temporary Surgeons: A. D. Wall to *Maidstone*; H. P. Margetts to *Europa*, additional; A. S. Green to *Highflyer*; G. H. Fitzgerald to *Agamemnon*; and A. C. C. Craig to *Minotaur*.

J. M. Mackenzie, F. M. Allen, S. A. McC. Thompson, J. N. Morris, R. Johnston, C. V. Patrick, E. H. Weatherall, A. Gibb, T. S. Storey, and F. M. Hilliard to be temporary Surgeon Probationers.

ARMY MEDICAL SERVICE.

Col. G. G. Adams retires on retired pay.

Temp. Lieut.-Col. Sir H. J. Stiles (Bt. Lieut.-Col., R.A.M.C., T.F.) to be temporary Colonel.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. (Bt. Col.) F. Smith and Lieut.-Col. W. C. Croly relinquish the temporary rank of Colonel on re-posting.

To be acting Colonels whilst employed as Assistant Directors of Medical Services of Divisions: Major (Bt. Lieut.-Col.) (temp. Lieut.-Col.) C. W. Holden, Lieut.-Cols. T. E. Fielding and P. H. Henderson, Capt. (acting Lieut.-Col.) W. G. Wright.

Capt. A. I. Fortescue relinquishes the acting rank of Lieutenant-Colonel on re-posting.

Major A. M. H. Gray, R.A.M.C. (T.F.), to be temporary Lieutenant-Colonel whilst specially employed.

To be acting Lieutenant-Colonels:—Whilst in command of a Medical Unit: Capt. (acting Major) J. A. Andrews, Temp. Major E. H. Marshall. Capt. (acting Major) G. S. Parkinson whilst employed as Assistant Director of Medical Services of an Army).

J. N. Sergeant to be temporary Major whilst employed at the Great Ballard Hospital.

To be acting Majors: Capts. J. B. A. Wigmore, T. F. P. Breen. Temp. Capts. C. Kingston, P. L. Blaber, G. MacK. Miller, E. F. G. Ward, G. D. Laing. Whilst specially employed: Temp. Capts. D. Murphy, K. B. Dickson, W. H. Clements.

The rank of the undermentioned is as follows: Temp. Capt. E. H. Roberts, Temp. Capt. J. A. Davidson.

Temporary Lieutenants to be temporary Captains: J. M. Smith, A. L. Vaughan, H. E. White.

R. H. Bridge, late temporary Captain, is granted the honorary rank of Captain.

Officers relinquishing their commissions:—Temporary Captains: F. E. Higgins and A. D. Crofts (on account of ill-health, and are granted the honorary rank of Lieutenant), A. A. E. Newth, R. H. Hutchinson, H. J. Simson, and J. W. Johnstone (on account of ill-health contracted on active service, and are granted the honorary rank of Captain), W. T. Williamson, R. J. Gordon, F. J. McCarthy, J. K. Stewart, W. Scott, A. J. M. Crichton, W. F. Evans, W. R. Tutt, C. R. Porter, F. McE. Sinclair, T. F. Saunders, S. W. Swindells, M. B. Arnold, H. A. Treadgold, J. N. MacDonald, H. S. Gaskell. Temp. Lieut. A. Watson.

GENERAL RESERVE OF OFFICERS.

Capt. (acting Major) F. E. Bissell to be acting Lieutenant-Colonel whilst in command of a Medical Unit.

SPECIAL RESERVE OF OFFICERS.

Lieutenants to be Captains: L. J. Vincent, G. R. Hubbard, J. A. Keen, H. Chadwick, L. Gill, J. G. Allan, H. B. Dodwell, J. F. Campbell, J. H. Brown, N. P. R. Galloway, W. W. Brown, A. Y. Milne, H. D. Apergis, D. J. Mackinnon, E. D. Spackman, F. E. Bendix, H. Taylor, J. Joels, C. Reid, C. Wood, H. B. Renton, G. L. Malcolm-Smith, F. Jones, J. L. Rowlands, H. G. Morris-Jones, R. R. Evans.

To be Lieutenants: B. G. Derry; Second Lieut. D. Fergusson (from Unattached List, T.F.): J. A. Dawson, A. C. Hill, A. McKenzie, J. A. Ross, W. Buchan, G. S. Escoffery (from Aberdeen University Contingent, O.T.C.); J. W. W. Newsome, B. L. Slater, V. D. Wyborn (from the University of London Contingent, O.T.C.); D. W. Sinclair (from Edinburgh University Contingent, O.T.C.); D. C. Bowie, A. J. Macartney (from Glasgow University Contingent, O.T.C.).

In THE LANCET of Sept. 14th, 1918, p. 374, the last two paragraphs under Royal Army Medical Corps should have come under the heading Special Reserve of Officers which immediately follows.

TERRITORIAL FORCE.

Officers restored to the establishment: Lieut.-Cols. F. Kelly, C. H. Howkins, C. T. Green, E. V. Gostling, W. R. Matthews, H. Collinson, A. M. McIntosh, E. C. Montgomery-Smith; Majors D. F. Todd, F. E. A. Webb, A. Bird, C. H. Lindsay, A. E. Kidd, D. Rorie, H. Richardson, R. B. Carslow, H. A. Howes, J. Hobbs; Capts. W. A. Valentine, S. F. St. J. Steadman, J. L. Joyce, M. Coplans, A. C. McMaster, A. Leggat, S. S. Greaves, G. Finch, J. Everidge, G. W. Shore, H. A. Lucas, E. Smeed, L. Courtauld, F. Roberts, A. W. Stott, C. W. Wirgman, A. J. Campbell, H. F. Humphreys, W. B. Keith, H. M. Calder, C. E. H. Milner, G. McConnell, C. E. W. McDonald, A. B. Pettigrew, A. G. S. Logie, W. A. Hooton, J. D. Lickley, A. G. Hebblethwaite, C. D. Rogers, W. Tresawna, A. R. Moodie, W. Longley, A. B. Jamieson, T. S. P. Parkinson, A. C. Alport, G. F. Stones, F. W. C. Brown, P. G. Doyne, C. G. Skinner, J. Fenton, J. A. Willett, L. N. Reece, R. Armstrong, W. K. Legassick, A. E. Campbell, B. L. Davis, C. A. Raison, W. Alexander, A. A. McKenzie, A. G. Reid, D. Cameron, J. Chalmers, A. C. Smith, E. McM. Dunlop, A. C. Hepburn, D. Campbell, J. Steele, J. W. Anderson.

Lieut.-Col. (Bt. Col.) J. P. Bush to be an Assistant Director of Medical Services and remain seconded.

Major R. A. Farrar is seconded for duty under the Colonial Office.

Major A. C. Farquharson, from Sanitary Service, to be Major.

Lieut.-Col. H. H. Tooth and Major G. E. Gask are seconded whilst temporary Colonels, Army Medical Service.

Capt. (temp. Lieut.-Col.) R. A. Veale reverts to the temporary rank of Major, and is restored to the establishment.

Capt. (acting Major) J. M. Whyte relinquishes his acting rank on ceasing to be specially employed.

Capts. R. Armstrong, C. A. Raison, and G. M. Benton to be acting Majors whilst specially employed.

Capt. J. Gutch is seconded for duty overseas.

Major G. R. Murray and Capts. J. M. Whyte and H. J. Slade are restored to the establishment.

Capt. (acting Major) C. P. Lapage relinquishes his acting rank, and is seconded for duty with a General Hospital.

Capt. G. L. Travis, from T.F. Reserve, and Lieut. J. W. Munro to be Captains.

Capt. (temp. Lieut.-Col.) W. Lister relinquishes his temporary rank on ceasing to command a Field Ambulance.

Capt. D. J. Scott to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

TERRITORIAL FORCE RESERVE.

Capt. A. C. Young, from R.A.M.C., to be Captain.

ROYAL AIR FORCE.

Dental Branch.—D. Campbell is granted a temporary commission as Second Lieutenant.

INDIAN MEDICAL SERVICE.

The King has approved the grant of temporary or acting rank to the following officers:—To be temporary Colonels: Lieut.-Col. E. F. Hugo while holding an appointment as Consulting Surgeon of a Force; Lieut.-Col. H. G. Melville while holding an appointment as Consulting Physician of a Force; Major and Bt. Lieut.-Col. F. A. F. Barnardo while holding an appointment as A.D.M.S. To be temporary Lieutenant-Colonels while holding appointments as Assistant Directors-General, Indian Medical Service: Major R. A. Needham and Major H. Ross. To be Acting Major whilst employed as Major with a Casualty Clearing Station: Capt. J. G. B. Shand.

The King has approved of Dental Surgeons, Royal Naval Volunteer Reserve, wearing Orange distinction cloth in conjunction with the rows of Gold Lace on the sleeve and shoulder strap.

POST-GRADUATE COLLEGE, WEST LONDON HOSPITAL.—During next week clinics will be held each week-day at 2 P.M., Wednesday, Friday, and Saturday also at 10 A.M.

Correspondence.

"Audi alteram partem."

NASO-PHARYNGEAL INFECTION AT THE ONSET OF CEREBRO-SPINAL FEVER.

To the Editor of THE LANCET.

SIR,—The question of the constancy of the meningococcus in the naso-pharyngeal secretion of the patient at the onset of cerebro-spinal fever is obviously a matter that will be decided in course of time by further bacteriological investigations. Nevertheless, before dealing with the letter of Staff-Surgeon P. Fildes in THE LANCET of Sept. 14th, I will summarise the evidence in favour of this view.

It has been pointed out previously[1] that whereas v. Lingelsheim in his early investigations during the Silesian outbreak only got 23 per cent. of positive results, later by improved technique he got 94 per cent. of positives. In their excellent monograph[2] Netter and Debré express themselves as follows upon this matter (p. 42):—

"Lastly, the multiple conditions necessary for the culture of the meningococcus are sometimes difficult to realise. It results from all these circumstances that in such research, as in every biological test that is a little delicate, the errors committed are frequent enough. But these errors are errors 'en moins,' and the positive cases have a value very great, whereas a doubt can persist for each negative result."

After taking the causes of error into account, however, they say (p. 32):—

"Il paraît légitime de dire *que le méningocoque doit se trouver d'une façon constante dans le rhinopharynx de méningitiques pendant les premiers jours de leur maladie.*" The italics are those of Netter and Debré.

The tendency of the coccus to vanish from the naso-pharynx as the disease progresses has been referred to previously.

At the beginning of the present outbreak, after the various serological types of the meningococcus had been defined, one of the first steps taken was to investigate this question of the presence of the meningococcus in the naso-pharynx of the patient at the onset of the disease for the special purpose of seeing if it was of the same type as was to be found in the cerebro-spinal fluid. The full result of observations carried out at St. Bartholomew's Hospital by Professor F. W. Andrewes and Dr. R. G. Canti on 25 consecutive cases of bacteriologically proved cerebro-spinal fever has been published by the latter.[3] In all of them the same type of meningococcus was present in the naso-pharyngeal secretion as was found in the cerebro-spinal fluid. Quite independently of this research, Captain Martin Flack, R.A.M.C. (now Lieutenant-Colonel, R.A.F.), paid special attention to the same problem when he was in charge of the London District Cerebro-spinal Fever Laboratory, with the result that in all of 32 cases he found meningococci in the naso-pharyngeal secretion, and in 30 of them these were of the same type as was obtained from the cerebro-spinal fluid. Both Captain Flack and Dr. Canti found it necessary in some cases to make several attempts before they succeeded.

Now, Sir, in view of this very positive evidence afforded by the literature, and the confirmation of it obtained by independent observers during the present outbreak, I stated it as my opinion, in the report to the Medical Research Committee in 1917, that this constant presence of the meningococcus in the naso-pharynx of the patient at the onset indicated that every case was really an instance of a carrier developing the disease. It never occurred to me that this view would be misinterpreted to mean that I referred to chronic carriers, and I can accept no responsibility for such mistakes. I purposely avoided any reference to the duration of such carrying by the patient before he developed the disease, because scant information was then available on this matter. The fact that, as a rule, only a comparatively small number of persons whose naso-pharynx becomes infected with the meningococcus themselves develop the disease has, of course, been known for years and is no new discovery. Individual susceptibility obviously is a most important factor in determining an attack of cerebro spinal fever.

Coming now to the outbreak of cerebro-spinal fever at X, I must protest most strongly against the inaccurate and unjust interpretation put by Staff-Surgeon Fildes upon the remarks in my reply to Major J. Dorgan in your issue of August 17th. I should have thought it unnecessary to point out that the bacteriological diagnosis of cerebro-spinal fever is complete when the meningococcus has been cultivated from the cerebro-spinal fluid and identified, but incomplete when the coccus is not isolated from the cerebro-spinal fluid and examined. Had Staff-Surgeon Fildes grasped the particulars of this outbreak given by Major Dorgan he would have noticed that in Major Dorgan's letter it is admitted that the meningococcus was not cultivated from the cerebro-spinal fluid of the patient in a considerable proportion of the cases. It was, of course, to these cases only that I referred when I pointed out that the bacteriological diagnosis in such cases was incomplete, and especially to those where the fluid was clear or almost clear, diplococci scarce in films of the centrifugalised deposit, and the patient recovered after a transient illness. The naso-pharyngeal evidence—such as it was—was also negative. Nevertheless, it is cases of this "mild and usually unrecognised" type that Major Dorgan regards as of prime importance in the spread of the disease. I am surprised that a bacteriologist of Staff-Surgeon Fildes' experience has not realised the possible source of error from skin diplococci in films of the deposit of cerebro-spinal fluid in such cases where cocci are scarce and are only found after prolonged search. Having been misled by such skin diplococci myself on making prolonged microscopic investigation of films of clear cerebro-spinal fluid from a case of meningismus, I know the fallacy to be very possible.

The other point mentioned by Major Dorgan and Staff-Surgeon Fildes—namely, the failure of Captains R. R. Armstrong and J. A. Glover to grow the meningococcus from the naso-pharynx in a proportion of cases of cerebro-spinal fever at X and in the London District respectively—does not prove anything. It is true that Captains Armstrong and Glover have worked in the Central Laboratory, but neither they nor I lay the stress upon these negative results that Major Dorgan or Staff-Surgeon Fildes does. Officers so busy at the practical prevention of cerebro-spinal fever, as they were at the time, are far too much occupied in performing their military duties and have too little time to spare to carry out researches on the naso-pharyngeal secretion of cases once the bacteriological diagnosis has been established in the usual manner by isolation of the meningococcus from the cerebro-spinal fluid.

I am, Sir, yours faithfully,

M. H. GORDON,
Lieutenant-Colonel, R.A.M.C.

HYPNOSIS IN HYSTERIA.

To the Editor of THE LANCET.

SIR,—I join with Dr. Thomas Lumsden (THE LANCET, August 17th, p. 219) in congratulating Major A. F. Hurst and Captain J. L. M. Symns on arriving at a rapid method of cure in war neuroses. The same feelings may be extended to Major William Brown in respect of the treatment of cases of shell shock in an advanced neurological centre, but I trust that this distinguished psychologist will pardon me if I comment on some of his remarks. He says that he agrees with Pierre Janet that only hysterical patients can be hypnotised—in fact, that, as Charcot said many years ago, hypnosis is an artificial hysteria. Surely, this claim of Charcot has long been completely withdrawn. It is a remarkable fact that although Charcot was perhaps the only man of eminence whose professional reputation was raised by his dealings with hypnotism, most of his work thereon is now seen to have been mistaken—a following of a blind alley from which his disciples have gradually returned. Charcot's leading phenomena were of a type which has seldom since been obtained. The once celebrated three stages of the *grand hypnotisme* are hardly anywhere now to be seen. Not that other hypnotists could not obtain the phenomena, but experience convinced them that the sequences and symptoms on which Charcot laid stress as a proof of the relationship of hypnosis to hysteria were merely elaborate products of the long-continued and, so to say, endemic suggestions of the Salpêtrière. One of the supporters of the practice of the hospital allowed that only a dozen cases of true hypnosis had occurred there in ten years, and that a large proportion of the experiments had been made upon one subject who had long been an inmate of that hospital.

Pierre Janet's theory that only hysterical patients can be hypnotised rests on the assumption that the presence of the secondary self is always a symptom of hysteria. Now this generalisation is far too wide. Some cases of secondary consciousness correspond with Janet's description, others, however, present conditions which are its exact opposite. Thus, while hysteria is a prominent symptom in cases of spontaneous secondary consciousness, it is, on the other hand, not necessarily connected in any way with its hypnotic forms. Thousands of healthy men absolutely devoid of any trace of hysteria have been hypnotised, while hysteria itself instead of favouring the induction of hypnosis renders it more difficult. In April, 1892, Schrenck-Notzing published the result of his first International Statistics of Susceptibility to Hypnosis. Fifteen observers in different countries published returns which showed without reference to sex, age, or health, that they had tried to hypnotise 8705 persons, with 519 failures—i.e., only 6 per cent. were uninfluenced. Vogt tried 119 subjects; none were refractory. Van Eeden and Van Reuterghem, from May 5th, 1887, to June 30th, 1893, attempted to hypnotise 1089 persons and only failed with 58, or 5·33 per cent. Liébault, from 1887 to 1890, tried to hypnotise 1756; his failures amounted only to a fraction over 3 per cent. Bernheim, from 1882 to 1889, attempted to hypnotise 10,000 persons and he succeeded in over 80 per cent. Wellerstrand's failures were 3·7 per cent. out of 3209 he tried to influence. Later on he tried to influence 6500. The percentage of failures had decreased. Forel succeeded with over 95 per cent. Milne Bramwell's experience varied from 100 per cent. in one group to 78 per cent. in another. Later experience of susceptibility is still more evident. Henry S. Munro, of Omaha, Nebraska, demonstrated his methods to approximately 5000 American physicians on approximately 5000 subjects, these subjects being taken at random from the street—absolute strangers. The result was that practically every individual who gave his consent to coöperation was hypnotised or placed in a condition of suggestibility, without a failure in 1 per cent. of the cases. I have tried Dr. Munro's method in a fair number of cases and have practically had the same result. This seems to prove that about 80 per cent. of all mankind can be hypnotised, and as Major Brown says that only the hysterical can be hypnotised, he admittedly must believe that three-quarters of the globe is hysterical or conclude that nearly everyone is not quite right in the head.

I am, Sir, yours faithfully,

J. R. O'BRIEN.

Captain, R.A.M.C.

A NASAL DRILL IN THE TREATMENT OF ADENOIDS.

To the Editor of THE LANCET.

SIR,—An adenoid resembles a pig; for there are more and better ways of killing it than by cutting off its head. It must be at least 20 years since Arbuthnot Lane taught that suitable breathing exercise, religiously performed, would in many cases obviate the necessity for operation. About this time a Swedish lady—I think her name was Mrs. Conn—claimed that her gymnastic system, which included deep nasal breathing, would cause the disappearance of adenoids. In an article which appeared in your columns on May 1st, 1909, I pointed out that treatment by thyroid extract directed to the relief of nocturnal enuresis not infrequently caused the disappearance of adenoids, and called attention to the fact that running of the nose was one of the earliest symptoms of thyroid feeding which was excessive either in dosage or time.

Now comes Dr. Isabel Ormiston's interesting article in your issue of August 24th explaining Mrs. E. Handcock's sneezing cure; and, in your issue of Sept. 14th Mr. Walter C. Blaker's supporting letter, in which he records an illustrative case: a patient in whom—

"There was nasal obstruction and adenoid vegetations, no discharge, breath offensive, and she complained of a nasty taste in the mouth; appetite poor, and she was anæmic. There was considerable thickening over the bridge of the nose, and also behind both ears. She was dull, stupid, and apathetic, walked badly, had night terrors, and slept very badly. The skin was harsh and dry, and she had never perspired. Feet, hands, and abdomen were always cold."

I should be very much surprised to know that this child did not, in addition, suffer from nocturnal enuresis; for a more typical example of thyroid insufficiency has never been described. And yet all the symptoms disappeared under a discipline of artificially evoked sneezing! The interesting question then arises as to the mechanism by which stimulation of the nasal mucosa, as in Arbuthnot Lane's exercises and Mrs. Handcock's sneezing, produces a reflex stimulation of the thyroid gland. It looks very much as if, not only the antiseptic pituita, but the hormonic pituitary were in cause.

I am, Sir, yours faithfully,

Harley-street, W., Sept. 14th, 1918. LEONARD WILLIAMS.

TUBERCULOSIS IN DUBLIN.

To the Editor of THE LANCET.

SIR,—Your readers may remember the salient facts in a series of letters on the above subject which appeared in the numbers of THE LANCET for April 27th and the following weeks. It will gratify you and those of your many readers who have an interest in the welfare of the Irish capital to learn that on and from August 1st last the differences between the Tuberculosis Committee of the Corporation of Dublin and the Insurance Committee of the county borough of Dublin under the National Insurance Act, 1911, have been adjusted. In future the cases of insured tubercular patients will be dealt with by the medical officers of the Corporation, just as non-insured cases are dealt with at present. Thus the confusion and expense of the second and unnecessary machinery called into existence after March, 1917, are ended to the advantage of the sick and to the saving of public funds.

It was not until to-day that I learned from the secretary of the Insurance Committee that matters at issue between the Corporation and the Committee had been happily settled. I asked him why no notice of this important action had been communicated to the medical profession. He replied that the Approved Societies had been notified of the change, as required by the National Insurance Act. At my suggestion he will ask his Committee to inform the Dublin hospitals of the wise step which has been taken to once more unify the machinery for dealing with tuberculosis in this city.

I am, Sir, yours faithfully,

JOHN W. MOORE, M.D., D.P.H., F.R.C.P.I.

Dublin, Sept. 11th, 1918.

THE MANAGEMENT OF LUNACY PATIENTS.

To the Editor of THE LANCET.

SIR,—I am exceedingly gratified that you have kindly given so much space to the review of my book, "A Plea for the Insane." There are, however, some matters that I trust you will allow me to explain, as I fear from some parts of the review a wrong impression will be conveyed to your readers of my meaning.

(1) *With reference to approved homes for early cases by simple notification*, I fear I did not fully explain what I meant should be done with regard to such homes. I did mention the fact that I desired that an altered voluntary boarder's clause should be applied to private care, and not simply confined to licensed houses and registered hospitals. I forgot to mention that, personally, I never admit a case unless I receive definite proof that the patient wishes to come under my care for treatment. The large majority pay their own accounts and realise that they can leave whenever they like. While many suggestions with regard to notification have been made, none have carried with these the demand which I make for some official supervision and visitation of these notified cases.

(2) *With regard to* the severe censure upon me for stating the fact that very *little medicinal treatment* is carried out in our rate-supported asylums, surely this fault has been brought prominently before the public by many doctors, especially by Sir James Crichton Browne, whom I quoted. It is an acknowledged fact that illness is more rife among the insane than among the general population, and my accusation seems proved when I state the fact, taken from the Board of Control's Blue-book, that in the public asylums only 4*s.* 4*d.* per patient per annum is spent upon medicines and appliances, &c.

(3) *With regard to well-supervised mechanical restraint* as opposed to medicinal or manual restraint in some cases of acute suicidal tendency, I still maintain that it is the most humane form of restraint, and I am glad to have my opinion backed up by Sir George Savage, whose remarks can be seen in the *Medical Annual*, and also by that most kindly medical

superintendent, Dr. P. M. Deas, who for many years so well and so ably presided over Wonford House, Exeter. Nothing, to my mind, is worse than to see a suicidal patient struggling with two or three nurses or attendants, and I have often been told by such patients how much they appreciated the kindly supervised mechanical restraint that I had ordered.

I forgot to mention one case bearing on this subject. A lady under my care many years ago could not be kept in bed at night. She would get up and stand for hours. At last, fearing gangrene of her feet, as she was old and with a very feeble circulation, I adopted the simple restraint of a long sheet, carefully adjusted, which effectually prevented her getting out of bed and all went well. One day a commissioner when visiting my institution and noting the entry in the book ordered this restraint to be discontinued. I and her relatives protested, but to no purpose, and so the order was obeyed. In three months the unfortunate patient died of gangrene of both feet. I maintain that although wholesale restraint is wrong there are many cases in which its use is the most humane form of treatment.

In conclusion, let me say, I welcome criticism, and should a new edition be brought out, all that has been criticised by my reviewers will be carefully considered. All I have said with regard to public asylums has been boldly asserted by many well-known and experienced alienists, while my remarks regarding registered hospitals are absolutely taken from the Board of Control's Blue-books.

I am, Sir, yours faithfully,
LIONEL A. WEATHERLY, M.D.

Bournemouth, Sept. 7th, 1918.

THE PREVENTION OF VENEREAL INFECTION.

To the Editor of THE LANCET.

SIR,—I am gratified to find that so distinguished an authority as Sir H. Bryan Donkin agrees with my suggestion that women are entitled to at least equal protection from venereal disease as is provided in the case of men. The proposition has, indeed, only to be stated clearly and fairly for public opinion to realise how monstrous the present inequality is. It is not only unjust, but it is largely destructive of the effort to improve public health, in that it concentrates remedial action upon the minor focus of infection and neglects the major and infinitely more potent. Up to the present the attitude of society towards women of the class in question, whether of the professional, semi-professional, occasionally professional, or amateur class, has been to treat them as criminals, while not daring to adopt the theoretically logical and practically absurd position of making prostitution a crime.

In a spirit that savours more of cant than of morality they have been denied protection from disease, and their consequent sufferings have been regarded as the merited result of their mode of life and as an indirect and providential means of punishing the men who consort with them. They have accordingly been subjected to incessant harrying, and infinite pains have been taken to erect a barbed wire fence round them which kept no one in and no one out. The result of this attitude is seen in the appalling spectacle of venereal disease common alike to civilised and uncivilised communities.

Surely it is time to try something more consonant with the spirit of the New Testament and more agreeable to the teaching of science—sympathy, guidance, instruction as to the best method of preserving not only her soul from contamination but her body from infection, and scientific facilities of a nature to diminish both danger to herself and to the community. Compulsory regulation and examination have utterly failed. Let us try guidance and accessible facilities for the avoidance of danger.

I am, Sir, yours faithfully,
X. Y. Z.

Sept. 7th, 1918.

SOUTHMEAD INFIRMARY, BRISTOL.—At the last meeting of the Bristol board of guardians it was decided to erect a fourth temporary block for the accommodation of 100 additional military patients—orthopædic cases.

Miss M. A. Harvey, matron of Base Hospital No. 1, who was formerly matron of the 2nd Southern General Hospital, Bristol, before she went to France, is the first woman to be mentioned in Portuguese despatches.

The War.

THE CASUALTY LIST.

THE following medical officers appear among the casualties announced since our last issue:—

Killed.

Capt. J. Steel, M.C., R.A.M.C., attached Somerset Light Infantry, qualified at Glasgow in 1916, and thereupon joined up. The award of the M.C. was officially announced last Monday.

Died of Wounds.

Surg. A. R. MacMullen, D.S.C., R.N., was educated at the London Hospital and at Cambridge University, and qualified in 1913. The award of the Distinguished Service Cross was recorded in THE LANCET of March 4th, 1916, p. 537.

Capt. G. R. Cowie, South African Medical Corps, attached S.A. Brigade, R.H.A., was educated at Oxford University and qualified in July, 1917, thereupon joining up.

Lieut. W. M. Heald, R.A.M.C., attached Lancs Fusiliers, was educated at St. Bartholomew's Hospital, London, and at Cambridge University, and qualified in the early part of this year. After a short period of service as house surgeon at St. Bartholomew's he joined the R.A.M.C.

Died.

Lieut. T. M. Boyd, R.A.M.C., qualified at Belfast in 1917, and joined up two months later.

Wounded.

Staff-Surg. W. J. McCracken, D.S.O., M.C., R.N.
Capt. A. W. Holthusen, R.A.M.C., attd. S. Staffs Regiment.
Capt. T. V. Somerville, M.C., R.A.M.C., attd. Highland L.I.
Capt. J. R. A. Marin, Canadian A.M.C.
Surg. J. G. Dobson, R.N.
Surg. R. K. Shaw, R.N., attached R.N.D.
Major C. McN. McCormack, M.C., R.A.M.C.
Capt. J. P. S. Cathcart, Canadian A.M.C.
Capt. S. E. Holmes, Canadian A.M.C.
Capt. W. C. Walsh, Canadian A.M.C.
Capt. E. V. Beaumont, R.A.M.C., attd. Duke of Wellington's Regiment.
Capt. R. K. H. Gillespie, R.A.M.C.
Capt. H. J. Shone, R.A.M.C.
Capt. H. Black, Canadian A.M.C.
Capt. A. H. Donaldson, R.A.M.C., attached R.H.A.
Lieut.-Col. D. Ahern, D.S.O., R.A.M.C.
Capt. C. Cairne, R.A.M.C., attached R.E.
Lieut. W. F. Kivlichan, R.A.M.C.
Capt. J. P. McGreehin, R.A.M.C., attached Royal Fusiliers.
Capt. R. Ward, M.C., R.A.M.C., attached London Regiment.
Maj. H. S. Hollis, R.A.M.C.
Capt. H. B. Sherlock, M.C., R.A.M.C., attached King's Own Scottish Borderers.
Lieut.-Col. E. R. Selby, Canadian A.M.C.

Previously reported Missing, now reported Prisoner in German Hands.

Major N. A. A. Hughes, R.A.M.C.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Second Lieut. (acting Capt.) C. F. Sandoe, M.C., Duke of Cornwall's Light Infantry, killed in action, second son of Dr. J. W. Sandoe, of Broad Clyst, Exeter.

Lieut. R. H. Sanders, R.E., attached R.A.F., killed whilst flying in England, eldest son of Dr. H. Sanders, of Hampden Park, Sussex, late of Hampstead, London.

Second Lieut. M. B. Cassidy, Irish Guards, killed in action, youngest son of Dr. J. L. Cassidy, late of Harley-street, London.

Capt. E. S. Davies and Lieut. E. O. Davies, both North Staffs Regiment, and killed in action, sons of the late Dr. G. Davies, of Bayswater, London.

THE HONOURS LIST.

A very lengthy list of awards to officers for their gallantry and devotion to duty in the field was issued on Monday last, and we purpose commencing the publication of the names of the medical section next week.

FOREIGN DECORATIONS.

Serbian.

Order of the White Eagle.—2nd Class: Lt.-Gen. Sir A. Keogh, G.C.B., G.C.V.O., ret. pay. 4th Class: Lt.-Col. C. H. Straton, R.A.M.C.

Order of St. Sava.—3rd Class: Temp. Col. L. S. Dudgeon, C.M.G., A.M.S.; Lt.-Col. C. B. Martin, R.A.M.C. 4th Class: Temp. Capt. R. C. Brown, R.A.M.C.; Temp. Capt. N. S. Carmichael, R.A.M.C.; Capt. B. Hughes, R.A.M.C.; Temp. Lt. A. R. Jennings, R.A.M.C.; Temp. Capt. T. W. E. Ross, R.A.M.C.; Temp. Maj. J. W. Struthers, R.A.M.C. 5th Class: Temp. Capt. J. T. Carson, R.A.M.C.; Temp. Lt. A. F. Martin, R.A.M.C.; Capt. G. S. Davidson, R.A.M.C., S.R.; Temp. Capt. F. P. Wigfield, R.A.M.C.

Italian.

Order of St. Maurice and St. Lazarus.—Officer: Col. T. du B. Whalte, C.M.G. Cavalier: Maj. G. W. W. Ware, D.S.O., R.A.M.C.

Order of the Crown of Italy.—Officer: Col. R. W. Wright, C.M.G., R.A.M.C.

Italian Bronze Medal "della Salute Publica."—Capt. J. J. H. Beckton, R.A.M.C.

PHARMACISTS AND VOLUNTEER SERVICE.

The general rule that men exempted from military service must, unless the tribunal orders to the contrary, join the Volunteers threatened to have a prejudicial effect on the national pharmaceutical service. A pharmacist is expected to be in or about his pharmacy at all times, and, as a matter of fact, most of them still "live over the shop." A large proportion of the qualified assistants are in the Army, so that, as a general rule, there is now only one pharmacist for one shop, and it is obviously impossible for a pharmacist to conform strictly to his obligations under the National Insurance Acts and at the same time dig trenches and fight sham fights. On representations from the Pharmaceutical Society the authorities have recognised the difficulties and taken steps to remove them by issuing a memorandum on the subject, which is taken as an instruction to tribunals, that it is generally inappropriate that practising pharmacists should be required to undertake the Volunteer obligation.

Obituary.

JOSEPH KIDD, M.D. KING'S COLL., ABERD.

THE death occurred of Dr. Joseph Kidd, at Hastings, on August 20th, after a few days' illness, in his ninety-fifth year.

Joseph Kidd was born at Limerick in 1824, the seventeenth of 18 children. His grandfather was a solicitor in the same town, and his father dealt in corn for exportation by ships calling at the Port of Limerick. His mother came of a Quaker family, a fact which had a certain influence in the development of his character. He received a good general and classical education at a Quaker school in Limerick, where he acquired a love for classical authors that he never lost throughout his long life. During his spare hours he often gave clerical assistance in his father's business, which proved of use to him in later years. In 1841, when 17 years of age, he became a pupil of Dr. O'Shaughnessy in Limerick. On the opposite side of the road lived another doctor, one of whose pupils, Richard Quain, afterwards acquired a great reputation as a physician. In 1842 he became assistant to Dr. Walter in Dublin, with whom he obtained experience in surgery, dispensary, and visiting practice, the value of which he always gratefully acknowledged. During his two free hours in the day he attended the course of lectures necessary for the diploma M.R.C.S. Engand, and among all the lectures which he heard Corrigan's impressed him most. He never ceased to regret that his duties at the surgery prevented him from attending Stokes's lectures. For six months he studied midwifery at the Rotunda Hospital in Dublin, where he was a witness of the wonderful reduction in mortality which followed the bold action of the then Master, who secured free ventilation of the wards by the simple process of cutting off the tops of the sash windows so that an open space of 2 feet was left above each window. Dr. Walter had been attracted by the principles of homœopathy, and his interest in the subject was shared by his pupil. Accordingly, when a vacancy for the post of house surgeon at the new Homœopathic Hospital in Hanover-square was advertised in the *Times* Kidd set off at once to London to make a personal application for the post, though he was not yet qualified to practise. On his arrival in London he found that 16 qualified men had already applied for the appointment, which was to be filled up in a month's time. He applied to the College of Surgeons to be admitted to the next examination for the diploma M.R.C.S., which was to take place in three weeks' time, but he was told that only 20 candidates could enter at one time and the list was full. Nothing daunted, he presented himself at the College on the day of examination, and finding a student whose courage had failed him at the eleventh hour he took his place, passed the examination, and shortly afterwards was elected house surgeon to the hospital. At the new Homœopathic Hospital he worked under Dr. Curie, father of Professor Curie, whose name with that of his wife is for ever commemorated in the discovery of radium. Thus he was introduced into practice on homœopathic lines. In 1847 during the Irish famine he was sent over to Bantry Bay by the Homœopathic Hospital to try the effect of the new treatment on the fevers which were devastating the country. An account of his experiences was published in a small volume entitled, "Narrative of a Mission to Ireland during the Famine and Pestilence of 1847."

On his return to England he commenced practice in the City of London, where he met with speedy success. At first his practice lay mainly among City men and their families, who in those days lived in or near the City. But in a few years he attracted patients of all classes from all parts of England and he divided his time between the City and the West-End, in both of which he had consulting-rooms. In 1853 he graduated M.D. of King's College, Aberdeen. Though he commenced his professional life as an avowed homœopathist, his outlook on medicine was always wider than this term would imply, and he never hesitated to adopt any form of treatment that seemed to promise relief. Indeed, it may be said that as he grew older the influence that homœopathy exerted on his practice gradually diminished, and in later years he disclaimed the title of homœopathist. Yet at the same time he always held fast to the opinion that there is a truth contained in the doctrine of homœopathy which at times supplies a clue to the treatment of obscure cases. But his success in practice and the extraordinary influence he exerted on his patients, both high and low, were entirely due to his personal qualities. In person he was tall and handsome, and his manner was unaffected and sympathetic. Sanguine and optimistic to a degree, he inspired his patients with his own confidence in his treatment. He was deeply religious, and his faith in spiritual things found its counterpart in his profound faith in drugs and other forms of treatment. From an early period he adopted the practice of prescribing only one drug at a time so as to be better able to study the action of individual remedies. A large part of his success must be attributed to his careful survey of small details. This habit undoubtedly helped to create the confidence reposed in him by his patients. His fertility of resource was extraordinary and at times was almost embarrassing. He had an accurate knowledge of human nature, which lay at the root of his skilful management of men and women. He trusted little to written notes, but he seldom forgot a name or an important fact. For many years he made a large income but no one cared less for money, and he gave freely to those that needed help, as many a poor patient has gratefully testified.

Though his reputation as a homœopathist cut him off from association with the consulting physicians of the day, except in the celebrated case of Lord Beaconsfield, he had frequent consultations with some of the leading surgeons of his time. Among these may be mentioned Sir James Paget, Sir Henry Thompson, Sir Spencer Wells, Lawson Tait, Lister, and in later years Sir Frederick Treves and Sir Rickman Godlee.

He retained his mental and bodily powers far beyond the ordinary limits of age, and he only retired from practice when he had reached his ninetieth year. He was twice married, first to Sophia, daughter of George Mackern, of Limerick, by whom he had eight children, and secondly to Frances, daughter of Robert Rouse, of Balham, by whom he had seven children. Four sons, Percy, Walter, Leonard, and Frank, and one daughter, Mary, have followed their father's profession.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON).—The following awards have been made:—Burney Yeo Scholarship: A. D. Porter, Pembroke College, Cambridge; H. L. Rayner, Balliol College, Oxford. Senior Scholarship, Tanner Prize, and Todd Prize and Medal: L. M. Moody. Class Prizes: Surgery and Psychological Medicine, A. N. M. Davidson; Obstetric Medicine, H. Kamal; Forensic Medicine, H. N. W. Collins; Hygiene and Diseases of Children, E. A. Crichlow.

URBAN VITAL STATISTICS.

(Week ended Sept. 14th, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality was 11·3, against 11·2 and 11·9 per 1000 in the two preceding weeks. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 10·5, or 0·9 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 2·0 in Swindon, 3·3 in Barrow-in Furness, and 3·8 in Gloucester, to 17·8 in Lincoln, 17·9 in Grimsby, and 18·0 in Dudley. The principal epidemic diseases caused 432 deaths, which corresponded to an annual rate of 1·4 per 1000, and included 346 from infantile diarrhœa, 27 from whooping-cough, 24 from diphtheria, 19 from measles, 10 from scarlet fever, and 6 from enteric fever. The deaths from diarrhœa, which had been 305, 435, and 431 in the three preceding weeks, further declined to 346, but were 84 in excess of the number registered in the corresponding week of last year; 71 deaths belonged to London, 32 to Liverpool, 20 to Birmingham, 17 to West Ham, and 14 each to Leeds and Sheffield. The 778 cases of scarlet fever and 953 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 30 and 78 above the respective numbers remaining at the end of the previous week. Of the total deaths in the 96 towns 115 resulted from violence. The causes of 34 deaths were uncertified, and included 4 in Birmingham, and 3 each in Nottingham, Liverpool, Preston, and Hull.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 10·6, against 9·4 and 10·9 per 1000 in the two preceding weeks. The 235 deaths in Glasgow corresponded to an annual rate of 11·0 per 1000, and included 24 from infantile diarrhœa, 6 from whooping-cough, 4 from diphtheria, and 1 each from measles and scarlet fever. The 69 deaths in Edinburgh were equal to a rate of 10·8 per 1000, and included 3 from infantile diarrhœa and 1 each from measles and diphtheria

Irish Towns.—The 146 deaths in Dublin corresponded to an annual rate of 19·1, or 1·8 per 1000 above that recorded in the previous week, and included 24 from infantile diarrhœa and 4 from whooping-cough. The 109 deaths in Belfast were equal to a rate of 14·5 per 1000, and included 9 from infantile diarrhœa.

VITAL STATISTICS OF LONDON DURING AUGUST, 1918.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 3·2 per 1000 of the population, estimated at 4,026,901 persons; in the three preceding months the rates had been 4·1, 4·5, and 3·5 per 1000. The lowest rates in August were recorded in Paddington, Hammersmith, the City of Westminster, Hampstead, Holborn, Wandsworth, and Lewisham; and the highest rates in Finsbury, Bethnal Green, Stepney, Southwark, and Bermondsey. The prevalence of scarlet fever was slightly less than in the preceding month; this disease was proportionally most prevalent in Finsbury, Bethnal Green, Stepney, Southwark, Bermondsey, and Battersea. The Metropolitan Asylums Hospitals contained 690 scarlet fever patients at the end of the month, against 786, 846, and 753 at the end of the three preceding months; the weekly admissions averaged 101, against 129, 127, and 105 in the three preceding months. Diphtheria was considerably less prevalent than in any recent month; the greatest proportional prevalence of this disease was recorded in Finsbury, Bethnal Green, Stepney, Southwark, Bermondsey, and Deptford. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1358, 1232, 1179, and 918 at the end of the four preceding months, numbered 886 at the end of August; the weekly admissions averaged 107, against 143, 202, 165, and 122 in the four preceding months. The prevalence of enteric fever was about equal to that in the preceding month; of the 29 cases notified in August 6 belonged to Wandsworth, 3 to Hammersmith, 3 to Woolwich, 2 to Poplar, 2 to Southwark, and 2 to Greenwich. There were 32 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 32, 40, and 23 at the end of the three preceding months; the weekly admissions averaged 6, against 5, 6, and 4 in the three preceding months. Erysipelas was proportionally most prevalent in the City of London, Shoreditch, Bethnal Green, Stepney, and Southwark. The 8 cases of puerperal fever notified during the month included 3 in the City of Westminster, 2 in Chelsea, and 2 in Poplar. Of the 10 cases of cerebro-spinal meningitis 2 belonged to Hackney and 2 to Wandsworth; while of the 4 cases of poliomyelitis 2 belonged to Stepney.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ended August 31st the deaths of 3118 London residents were registered, equal to an annual rate of 10·1 per 1000; in the three preceding months the rates had been 13·7, 11·8, and 14·8 per 1000. The death-rates ranged in August from 5·7 in the City of London, 7·3 in Woolwich, 7·8 in Lewisham, 8·1 in St. Marylebone, 8·4 in Hampstead, and 8·6 in Deptford, to 11·2 in Battersea, 11·4 in Holborn, 11·6 in Southwark, 11·9 in Hackney, 12·4 in Shoreditch, and 12·5 in Finsbury. The 3118 deaths from all causes included 244 which were referred to the principal infectious diseases; of these, 39 resulted from measles, 3 from scarlet fever, 27 from diphtheria, 29 from whooping-cough, 7 from enteric fever, and 139 from diarrhœa and enteritis among children under 2 years of age. No death from any of these diseases was recorded during the month in St. Marylebone. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in Hammersmith, the City of Westminster, Hampstead, Bermondsey, Camberwell, Lewisham, and Woolwich; and the highest in Fulham, St. Pancras, Stoke Newington, Finsbury, and Bethnal Green. The 39 deaths from measles were 24 below the average number in the corresponding period of the five preceding years, and included 9 in St. Pancras, 5 in Paddington, 4 in Lambeth, 3 in Stepney, and 3 in Wandsworth. The 3 fatal cases of scarlet fever showed a decline of 11 from the average. The 27 deaths from diphtheria were 1 less than the average; of these, 4 belonged to Finsbury, 3 to Islington, 3 to Stepney, and 3 to Southwark. The mortality from whooping-cough was lower than

* Including membranous croup.

in any preceding month since January, 1917, the deaths numbering 29, against an average of 42; 3 deaths belonged to each of the boroughs of Paddington, Fulham, Battersea, and Wandsworth. The 7 fatal cases of enteric fever were 3 less than the average number; of these, 2 belonged to Deptford. The 139 deaths from diarrhœa and enteritis among children under 2 years of age were about one-third of the average; of these deaths, 14 belonged to Fulham, 14 to Hackney, 14 to Lambeth, and 12 to Wandsworth. In conclusion, it may be stated that the aggregate mortality in London in August from these principal infectious diseases was 57 per cent. below the average.

Medical News.

THE distribution of prizes at Charing Cross Hospital Medical School (University of London) will take place in the out-patients' hall of the hospital on Tuesday, Oct. 1st, at 3 P.M., by Mrs. George Verity. The chair will be taken by Mr. George Verity, chairman of the hospital.

THE SCOTTISH UNIVERSITIES PARLIAMENTARY ASSOCIATION.—Medical practitioners who are graduates of Scottish universities will be interested to learn of the formation of this Association with the following as executive officers:—Chairman: Professor Sir Thomas Oliver, M.D., D.Sc. Honorary Secretaries: Professor W. J. R. Simpson, C.M.G., M.D., and Miss Ellen B. Orr, M.B., Ch.B. The Association has come into existence in consequence of the reconstitution of university representation in the House of Commons, and in view of the probability of a General Election, and the offices are for the present situated at 37, Russell-square, W.C. 1, where communications to the honorary secretaries should be sent.

Lindsey, Lincolnshire.—Asst. M.O. £400.
Margate, Royal Sea Bathing Hospital for Surgical Tuberculosis.—Surgeon. £200.
Much Wenlock, Salop, King Edward VII. Memorial Sanatorium.—Temp Asst. Med. Supt. £300.
National Hospital for Paralysed and Epileptic, W.C.—Registrar. £100.
Netley, Welsh Hospital.—Pathologist. Also Two M.O's. £400.
Plymouth, South Devon and East Cornwall Hospital.—M.O. for Venereal Diseases Department. £500.
Rotherham Hospital.—Jun. H.S. £150.
Sheffield Royal Infirmary.—Res. S.O. £200.
Southampton County Borough Isolation Hospital.—Res. M.O. £400.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Dumbarton and Dingle.

Births, Marriages, and Deaths.

BIRTHS.

GREENFIELD.—On Sept. 15th, at 142, Clonmore-street, S.W., the wife of Captain J. G. Greenfield, R.A.M.C., of a daughter.
JACOB.—On Sept. 16th, at South Hill Park, Hampstead, N.W., to Margaret, the wife of Captain L. G. Jacob, R.A.M.C., of a son
LONG.—On Sept. 16th, at Sandhills, Fleet, Hants, the wife of Major H. W. Long, R.A.M.C., of a daughter.

MARRIAGES.

DYKE—SMITH.—On Sept. 9th, at All Saint's Church, Llanelly, Caermarthenshire, Sidney Campbell Dyke, Captain, R.A.M.C., M.B., B.Ch. Oxon., to Janet Mary, younger daughter of Mr. and Mrs. W. Dickson Smith, Yr Hen Dy, Llanelly.
LAKE—STORMONT.—On Sept. 12th, at St. Mary's, Bryanston-square, Richard Lake, F.R.C.S., to Ellen, widow of Arthur Stormont and second daughter of Mr. and Mrs. Sapsworth, of Steyning.
MCCLOY—KYLE.—On August 31st, at Powerscourt Church, Captain John Moorcroft McCloy, R.A.M.C., to Kathleen Theodora, daughter of R. A. Kyle, Belfast.
ROBERTSON—DAVIES.—On Sept. 10th, at the Parish Church, Stroud, Major H. Playfair Robertson, R.A.M.C.(T.F.), to Doris Primrose, younger daughter of Mr. and Mrs. A. B. Davies, Dirleton House, Stroud.
ROPER—STATHAM.—On August 19th, at the British Consulate-General, Alexandria, Richard Roper, Captain, R.A.M.C., to Gladys, widow of the late Alfred Foster Statham and daughter of George Walker and Mrs. Walker, of Cairo.
SELLS—DAVIES.—On Sept. 11th, at St. John's Church, Southend, Roland Sells, Surgeon, R.N., to Frances Elizabeth, eldest daughter of Mr. and Mrs. T. Davies, Priory-street, Carmarthen.

DEATHS.

COLLINS.—On Sept. 12th, very suddenly, at St. Lawrence, Isle of Wight, Henry Beale Collins, Surgeon, R.N. (retired), Medical Officer for Kingston-upon-Thames, aged 66.
COWIE.—On Sept. 3rd, at a Casualty Clearing Station, of wounds, Graham Robertson Cowie, Captain, S.A.M.C., S. African Brigade, R.G.A., aged 27.
DAVIS.—On Sept. 12th, at his residence, Tower-street, West Hartlepool, E. H. Davis, M.R.C.S., J.P., aged 67.
HAMILTON.—On Sept. 16th, suddenly, at Heathfield, Heswall, Robert J. Hamilton, F.R.C.S. Edin.
HEALD.—On Sept. 8th, in hospital abroad, of wounds, Lieutenant W. M. Heald, R.A.M.C., attached Lancashire Fusiliers.
MUSSON.—On Sept. 10th, at King-street, Clitheroe, Lancashire, Alfred William Musson, M.B., B.C. Cantab., aged 53.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

EDITORIAL NOTICE.

In consequence of the pressure on our space and the shortage of paper, the Editor may be compelled to abbreviate communications, as an alternative to their rejection, when time does not allow them to be reconsidered by their authors.

Communications, Letters, &c., to the Editor have been received from—

A.—Dr. E. Anzà, Rome.
B.—Board of Agriculture and Fisheries, Lond.; Mr. V. Bonney, Lond.; Capt. D. D. Brown, R.A.M.C.(T.); Board of Trade, Lond.; Mr. J. Burns Edinburgh; Mr. C. H. Bubb, Lond.
C.—Charing Cross Hospital Medical School, Lond.; Dr. S. Coupland, Lond.; *Canada*, Lond., Editor of; Capt. J. C. Clayton, R.A.M.C.; Dr. S. D. Clippingdale, Lond.; Sir Anderson Critchett, Bart., C.V.O., Lond.; Mr. J. Cabburn, Lond.
D.—Mr. C. Dodgson, Lond.; Dr. T. V. Dickinson, Lond.; Dr. J. C. Drummond, Lond.

Notes, Short Comments, and Answers to Correspondents.

"TOY" KINEMATOGRAPHS.

AN inquest was held recently at Islington upon the body of an elderly woman who had been burnt to death in a fire caused by the ignition of a kinematograph film in the house in which she lived. A fellow-lodger had bought a lantern and films for domestic exhibition, but the precise way in which the accident occurred does not appear to have been known. The jury, however, found a verdict of accidental death, exonerating from blame the owner of the machine, and added a recommendation that the sale of "toy" kinema lanterns and films should be prohibited, a suggestion which the coroner endorsed and with which every sensible person should be in agreement. Celluloid films in professional hands and exhibited with due observance of all the precautions prescribed by the law are safe, and the absence of accidents in "picture-palaces" during the past few years is fairly conclusive that the precautions referred to are loyally carried out. Films in the hands of an amateur are quite another matter, and "toys" sold to grown-up persons with a view to their amusing the children pass by an easy transition into the children's hands for self-amusement. For this purpose films are no better fitted than unexploded bombs, not merely because they are made of celluloid, but because, owing to their shape and material, if once unrolled they are apt to coil themselves in unexpected directions, so that they may come in contact with fire when least expected to do so. With children accidental fires are likely to arise from their being given old strips of film pictures to play with, no less than from their being permitted to give exhibitions with the lantern on their own account. No doubt most parents would have too much sense to allow the films in any circumstances out of their own hands, but at the same time we do not forget the casual manner in which some fathers and mothers allow their offspring to handle pistols or to dress up in cotton-wool for festivities conducted round the pyramid of lighted candles represented by a Christmas tree.

A MEDIÆVAL MEDICAL AUTHOR.

"John of Burgundy," surnamed "A la Barbe," was a professor of medicine and a practitioner at Liége, and also the author of some medical works. Two treatises by him written in the later part of the fourteenth century are mentioned. The first upon the plague and the second, in point of time of composition, upon the Corruption of the Air as Cause of the Plague. The French originals are, apparently, lost, but a learned Jew, Benjamin C. Isaac of Carcassone, rendered the last treatise in Hebrew, and a copy of his work may be perused in Manuscript Bibliothèque Nationale, Paris, fonds Hebreu, No. 1191.

The other book may have been one in the library of Charles V. entitled, "Le Traité que les Maistres de Medicare les Astronomies de Paris firent de la Pestelence, que fisique appelle Epydimme en l'An de N.S. 1368." The work translated by Benjamin was dated 1363 and translated about A.D. 1370. In it John of Burgundy speaks of his earlier book, which he says he wrote after the ravages of the plague.

THE METROPOLITAN WATER-SUPPLY DURING APRIL, MAY, AND JUNE, 1918.

RAIN fell in April to the extent of 3·47 in., this being 1·78 of an inch above the average mean rainfall for that month during the previous 35 years. The effect of this increased fall on the raw river waters (Thames, Lee, and New River) according to chemical examination was a deterioration in quality as judged by the albuminoid nitrogen, permanganate, turbidity, and colour tests, and the bacteriological results showed a worse condition. There was a falling off in quality also, with some exceptions, in the filtered waters. Compared with last year, however, the filtered waters generally showed better results on chemical examination and not unsatisfactory results on bacteriological examination. In May the mean rainfall was 1·98 in., which is the average mean rainfall for that month during the previous 35 years. Compared with 1917, both the raw and filtered waters gave better results according to chemical examination, and a similar improvement was shown on bacteriological examination. June was a relatively dry month, the mean rainfall being 1 in., which is 1·23 of an inch below the average mean rainfall for that month during the previous 35 years. The chemical quality of both raw and filtered waters showed a general improvement and, compared with 1917, both chemical and bacteriological examination of the raw waters gave better results, and the filtered waters were satisfactorily free from *B. coli*. The work of control is obviously carried out with that vigilance which in the interests of the public health is demanded.

CERTIFIED OCCUPATIONS.

A NEW list of certified occupations (R. 136, revised, to be obtained from H.M. Stationery Office, price 1*d.*) has just been issued, and comes into operation on Sept. 26th. It supersedes all previous lists; and while it does not touch medical men in their professional capacity—for their cases are dealt with by the Central Medical War Committee—there are reservations with regard to hospitals and institutions which it may be useful to set out. Subject to the obtaining of an individual certificate of exemption, men engaged or employed as under will not be called up for service with the colours, provided they were before Jan. 1st, 1918, and have since been so engaged or employed:—

1. Hospitals, infirmaries, and similar public institutions for the treatment of the sick:

	Man certified if born in or before the year stated. Grade I.	Grade II.
(*a*) Steward	1878	1883
(*b*) Pharmacist, dispenser, male nurse, theatre attendant, mortuary attendant, out-patient porter	1880	1885
(*c*) All other classes of employees	1875	1880

Grade III. men must have been born in or before the year 1893 to obtain exemption.

2. Institutions for lunatics and institutions and houses for mental defectives under the Mental Deficiency Act, 1913:

Man employed in or about, to be treated as if in a certified occupation if recommended by the Board of Control; but the Board will not, without the concurrence of the Ministry of National Service, issue a certificate of recommendation (*a*) to any attendant in Grade I. who was born after 1883, or in Grade II. who was born after 1888; or (*b*) to any other employee in Grade I. who was born after 1878, or in Grade II. who was born after 1888.

THE PHYSICIAN'S TECHNIQUE.

MODERN developments in diagnosis and treatment make a much greater demand on the physician in regard to the use of instruments, especially of the syringe and needle type, than was the case even ten years ago. Their successful and expeditious use demands ingenuity and practice, and, above all, an orderly mind. Dr. H. Willoughby Gardner, senior physician to the Royal Salop Infirmary, has performed a useful service in tabulating in a small volume (Instruments and Apparatus required for the Investigation and Treatment of Medical Cases. Second edition. Shrewsbury: Wilding and Son, Ltd. 30 pp., interleaved. Price 1*s.*) the proceedings in such "medical" operations as aspirating the chest, investigating a fever of unknown (which should perhaps read "uncertain") origin, and administering a vaccine. The directions were drawn up for the use of nurses in the Royal Salop Infirmary, and the call for a second edition shows that they have been found useful by a wider circle, including, we believe, medical students and practitioners. We think that the usefulness of the brochure might be further increased by the introduction of a few simple diagrams, and a third edition would give the author the opportunity of correcting some blemishes in the way of misspelt words (guiac, opthalmoscope) and of a certain indecision in terminations (morph*ia*, strychn*in*, and hyosc*ine*; all occur on the same page).

MEDICAL INVENTIONS: DR. GATLING AND THE GATLING GUN.

To the Editor of THE LANCET.

SIR,—An American medical and military centenary occurred last week, which on account of the prowess of the United States Army in the battlefield seems worthy of notice.

On Sept. 12th, 1818, Dr. Richard Jordan Gatling was born in North Carolina. After spending some years in the practice of medicine, paying especial attention to small-pox, Dr. Gatling turned his fertile brain to the subject of armaments, and in 1861 invented the famous gun which bears his name, a gun which first came into use during the American Civil War, and has since been used all over the world.

I am, Sir, yours faithfully,

S. D. CLIPPINGDALE.

Holland Park Avenue, W., Sept. 15th, 1918.

PS.—In my note in THE LANCET of Dec. 22nd, 1917, upon Medical Inventions the name of Richard Gatling was included.

THE latest fasciculus of the *Athenæum* Subject Index to Periodicals (Bream's Buildings, London, E.C. 4) is a small but useful section dealing with language and literature in two subdivisions: Classified and Oriental; Modern. The price is 2*s.* 6*d.*

Nasal Drill in the Treatment of Adenoids.—An unsigned letter with this title, which we shall be happy to insert when duly vouched for, has reached us from an address in Harley-street, where several medical men have consulting-rooms. There is nothing particular in the contents of the letter to indicate the authorship to us.

Report
ON
THE ESSENTIAL CHARACTERISTICS OF SUCCESSFUL AND UNSUCCESSFUL AVIATORS.

WITH SPECIAL REFERENCE TO TEMPERAMENT.

BY T. S. RIPPON, M.R.C.S., L.R.C.P. LOND.,
CAPTAIN, R.A.M.C.; ATTACHED R.A.F.;
AND
E. G. MANUEL,
LIEUTENANT, R.A.F.

INTRODUCTION.

THE authors of this paper are respectively a pilot of 600 hours' experience and a medical officer stationed at an aerodrome. Their observations led them to the conclusion that the mark of the successful aviator was the possession of a suitable temperament, and in the following columns will be found a description of this faculty as shown in the cases they personally studied. In the second part of the paper will be found certain information obtained from experienced pilots, together with a few brief statistics, which are intended to show that the opinions of the authors are shared by pilots and confirmed by actual flying tests.

THE TEMPERAMENT OF THE SUCCESSFUL AVIATOR.

The enormous number of pilots who have qualified recently is a proof that the aviator is not a "super-man." It is true that we see certain men who perform marvellous "stunts," but when we come to talk to them and examine them with regard to physique and mentality we find that they are quite ordinary people.

Flying is not now confined to the public school boy, the cavalry officer, or the athlete. We take many of our pilots at present from the lower middle classes and some from the artisan class. The most useful method of discovering whether or not the candidate or pupil is likely to become successful is to study the life-history of the pilots whom we know to be efficient. This demonstrates the fact that there are many characteristics common to the successful pilot which are absent from the pupil who has been withdrawn from instruction in flying on account of lack of aptitude.

Sport.—The successful aviator has always the attributes of a sportsman. As a schoolboy he takes part in all forms of athletics and usually played for the school in one game at least. After leaving school he still keeps it up, and probably goes in for other kinds of sport—hunting, shooting, fishing, rowing, golfing, motoring, &c. He joins the Air Force because he is keen on flying, as it appeals to his sporting proclivities.

Character.—He possesses resolution, initiative, presence of mind, sense of humour, judgment; is alert, cheerful, optimistic, happy-go-lucky, generally a good fellow, and frequently lacking in imagination.

Age.—The majority of successful pilots are under 25 years of age, the explanation obviously being that the resiliency of youth enables them to accustom themselves more rapidly to a new occupation and to recover quickly from the strain and stress they are called upon to undergo.

High-spirited.—Anyone who has lived with pilots for any length of time cannot fail to notice that they possess in a very high degree a fund of animal spirits and excessive vitality.

Amusements.—When they have finished flying for the day their favourite amusements are theatres, music (chiefly ragtime), cards, and dancing, and it appears necessary for the well-being of the average pilot that he should indulge in a really riotous evening at least once or twice a month.

Alcohol.—Alcohol is taken freely by the older men, but the young, fit pilot serving at home hardly ever touches it. It is not necessary to legislate on the subject of alcohol for pilots; they are well aware of the danger of taking too much before flying. The desire for alcohol comes with "nerves," staleness and stress of service, but the fit pilot needs no stimulant. In so far that on active service it enables a man to sleep after an exciting day and promotes good-fellowship in the mess, its effect may be said to be beneficial, but for the young cadet and the fit pilot on home stations it is entirely unnecessary.

Marriage.—The majority of successful pilots are unmarried, and our own observations tend to show that marriage is a definite handicap owing to the increased sense of responsibility. If a man marries after he has flown several hundred hours, and flying has become automatic, marriage may not apparently affect him for some time. In some cases it may even make him steadier and more careful, but sooner or later it will in most cases have a definitely deteriorating effect.

Although this objection could be advanced for any branch of the service, yet a careful consideration will show that there are special reasons why marriage is an exceptional disadvantage to the pupil under instruction. The training of officers for the infantry, for example, is practically unaccompanied by danger, and it is only when drafted overseas that they may be said to begin to know fear. By this time, however, they have learned all their duties, and the discipline acquired will help them to face their possibilities. The pupil under instruction in flying, on the other hand, whilst learning to fly in conjunction with his other training, faces great dangers, in some ways almost as great as he will ever be called upon to undergo. Being generally in England, he has not the feeling that he is in the actual zone of hostilities, and the risks he takes are, as one might say, undergone in cold blood.

The unmarried man (faced with the possibility of crashing whilst doing his first solo) in most cases dismisses the thought or takes the risk in the same way as a horse-rider puts his mount at a fence in strange country. The married man has the knowledge of what death may mean to his wife and family, and, moreover, has the opportunity in many cases of discussing it with his wife and manufacturing in his own home a condition of nervousness which eventually becomes so great that he confesses to his instructor that he has completely lost his nerve.

Occupation.—We found that the best type of pilot was seldom drawn from a sedentary occupation, that those who had lived a sheltered life were not so good as those who had roughed it, and we discovered the interesting fact that most of those pilots who before they joined were in business or doing clerical work possessed considerable sporting aptitude, and as soon as they had finished work would hurry to the cricket or football field.

Hands.—One of the most important characteristics we have noticed in successful aviators is "hands." This characteristic is difficult to define, but may be described as follows. The horse-rider with good hands is able to sense the mentality of a horse by the feel of the reins and also to convey his desires accurately to his mount. We have never known of a man who has consistently been in the first flight in the hunting field making anything but a good pilot.

In the same way the pilot with good hands senses unconsciously the various movements of the aeroplane, and rectifies any unusual or abnormal evolutions almost before they occur. The skilful pilot appears to anticipate "bumps." He is invariably a graceful flyer, never unconsciously throws an undue strain on the machine, just as a good riding man will never make a horse's mouth bleed.

"Hands" appear to be congenital and cannot be acquired, although they may be improved and *vice versa*. Motor-car and motor-cycle racing, owing to the powerful grip that must be maintained to keep the machine on the track, tend to spoil "hands" even if this faculty was previously in existence. We have produced a mechanical contrivance for the purpose of demonstrating the difference between light and heavy-handed pilots with which we are at present experimenting and which we hope will prove of practical value.

The fighting scout.—The fighting scout is usually the enthusiastic youngster, keen on flying, full of what one might call the "joy of life," possessing an average intelligence, but knowing little or nothing of the details of his machine or engine; he has little or no imagination, no sense of responsibility, keen sense of humour, able to think and act quickly, and endowed to a high degree with the afore-mentioned quality, "hands." He very seldom takes his work seriously, but looks upon "Hun-strafing" as a great game.

Mechanical knowledge.—The question whether this type should possess a knowledge of mechanism, and of the whys and wherefores of flying is a very debatable point. The authors, however, desire to express their definite conviction that the less the fighting scout pilot knows about his machine from a mechanical point of view the better. From the very nature of his work he must be prepared to throw the machine about, and at times subject it to such strains that did he realise how near he was to the breaking-point, his nerve would go very quickly. It has not been possible as yet to obtain a sufficient body of evidence in support of this statement, owing to the unwillingness of pilots to confess their ignorance of engines, for reasons of *amour-propre*. Some of the most experienced and prominent pilots of the present day, however, uphold our conviction.

Examples of Successful Pilots.

The following are examples of flying officers who have demonstrated their ability to fly and also to fight.

1. Lieut. D. Educated at Stonyhurst. Joined the R.F.C. after leaving school at age of 17. Played football, cricket, racquets, fives, and golf—obtained his first eleven colours at school. Rode, hunted, and drove a motor. Was self-confident, self-reliant, quiet, had a keen sense of humour, was able to make a speech in public, and did not mind being alone. Courage and bravery with him was a "cult." After a distinguished career in France, and being decorated with the D.S O., he was wounded and became a test pilot. He was subsequently killed in an accident.

2. Capt. O. He was brought up on a farm and learned farming from a practical standpoint. He came of a stock of sporting farmers and was accustomed to hunt and shoot regularly as a boy. At the early age of 17 he took over the entire management of one of his father's farms which had previously been unsuccessful, and conducted it in such an able manner that it showed a profit at the end of the year. When war broke out he joined the infantry, where he obtained the Military Cross; he subsequently joined the R.F.C., and after obtaining a bar to his M.C. he had a serious accident, which has up to the present prevented him from resuming flying.

3. Lieut. L. This officer was brought up on a farm in South Africa. He was the descendant of the original Dutch emigrants to this colony. He was a skilful big game hunter and had the primitive instincts of hunting and fighting in a marked degree. At regular intervals he would disappear from his father's farm and wander by himself for months in the forest, subsequently returning and resuming his occupation. After a strenuous time with the infantry and unfit for further service on account of wounds, he became a pilot, and eventually was killed in France.

TABLE I.—*Answers to Questionaire.*

Series 1.

Serial number.	Age.	No. of hours flying.	Whether on active service.	Types of machines flown.	Married or single.	Occupation in civil life.	Is alcohol necessary?	Do you ride a horse?	Hunt?	Motor?	Favourite amusement.	Is marriage a handicap.

* About.

Mechan., mechanical; Mod., moderation.

4. Capt. C. Educated at Harrow and Cambridge. Played cricket, racquets, football, went in for swimming and gymnastics. Obtained his house colours for cricket and would have also got his first eleven colours but was expelled. At Cambridge he would probably have got his blue but for the fact that he was sent down. From the University he went to South Africa, where he played cricket to a considerable extent. He joined a cavalry regiment when war broke out, and subsequently transferred to the R.F.C. His favourite amusements are shooting and fishing. He rides, hunts, and motors. He does not read much, but prefers H. G. Wells when he does. He hates poetry, and prefers men's society to women. He was subsequently shot down by an anti-aircraft shell in France.

RESULTS OF INQUIRIES ADDRESSED TO FLYING MEN.

In order to satisfy ourselves as to the accuracy of our opinions we decided first of all to apply to fully qualified pilots for information, and issued a questionaire in which information on the following points was requested.

Age.—Number of hours flying. Whether in France with R.A.F. Types of machines flown.—Married or single.—What is the essential characteristic of a good pilot?—Is alcohol necessary for aviators?—What is your occupation in civil life?—What games and sports did you go in for? What was your special game? Do you ride a horse? Hunt? Motor?—What is your favourite (1) author; (2) poet; (3) amusement; (4) composer?—Is marriage a handicap to an aviator?—What are your views on the selection of candidates with regard to temperament, &c.?

We issued about 250 forms, some to the pilots in our own mess. We gave others to visitors who landed on the aerodrome, and several delivery pilots who flew to France took with them copies and distributed them among the pilots serving on active service. Out of the first issue only 47 were returned to us completed, and with one exception (which was of a frivolous nature) they have been faithfully reproduced. We subsequently issued 200 more and circulated them among pilots in various hospitals and obtained 15 more.

The result of an examination of the replies to the questionaire showed that our opinions agreed with the ideas of the pilots, and some of the answers were very instructive. The authors wish to point out, however, that in their opinion the pilots who answered the questionaire consisted chiefly of the older and more experienced men, and therefore cannot be said to be representative of all classes of aviators. When the questionaire was given to the younger and more frivolous pilots they frequently regarded it as a joke or stated that they had no opinion to express on the question as to the characteristics of pilots.

There are one or two other points which should be noticed also—viz., the question, "Do you ride a horse?" was answered almost invariably in the affirmative, but this does not mean that the pilot was necessarily an expert horseman. Moreover, the question, "Do you hunt?" was misunderstood in one case, the answer showing that the candidate did not realise that "fox-hunting" was meant.

It will also be noticed that in a few cases the replies are distinctly in opposition to the opinions expressed by the authors, but taking the answers generally it will be found that the opinions of the pilots as expressed in the questionaire agree in a remarkable extent with our own. The suggestion which we desire to make, which it is hoped will be of practical value to medical officers, is that every medical examination should be preceded by a few minutes' conversation to ascertain the temperament or make-up of the individual, after which the usual routine methods may be carried out. (See Table I.)

QUESTIONAIRE—SERIES I.

What is the essential characteristic of a good pilot?

The following answers were received:—

1. Quick decisions, control of all actions, and regular habits.
2. To deal quick with all kinds of situation.
3. Alertness and the clear-headedness of a sportsman.
4. Keenness, guts, judgment, and common sense.
5. Youth (under 30), must be quick thinking and alert, good nerves, and of a generally sporting nature.
6. Sound judgment rather than good nerves.
7. Good eyesight, strong, sound heart and lungs, young, alert.
8. A "sport."
9. Common sense as regards his flying.
10. Dash and courage, combined with coolness and quick decision.
11. Abandonment of care.
12. Lack of imagination. Ability to think and act quickly.
13. Light-handedness. No nerve, very little imagination. Quickness in thought and action. Perfect health. Mechanical mind.
14. No imagination. No nerves. Total abstainer. Very accurate shot. Full of confidence.
15. Has good hands. (Able to get the best out of a machine without hurting it.)
16. Clear-headed and quick decision, and no nerves.
17. Perfect health. Plenty of sport and exercise. A clear head.
18. Good judgment essential. Skill and daring, combined with a certain amount of reserve.
19. Keenness, health, guts, and cool head.
20. Sound judgment, must not be over-cautious; prepared to take risks, and reasonably sound physically.
21. Steadiness, accuracy of judgment, coolness and ability to rise to occasions.
22. Youth and nerve for a stunt pilot. Cool head and sporting instinct.
23. Good sportsman.
24. ?
25. Common sense.
26. Good judgment, quickness of decisions.
27. Guts.
28. Clear and steady brain, always prepared for an emergency.
29. Good nerves. Anyone who thinks and plays most outdoor sports and shoots.
30. For war purposes plenty of guts and good hands and nerves.
31. A capacity to keep and use one's head under all circumstances.
32. Clear head and plenty of pluck.
33. A happy-go-lucky; cool head.
34. Guts for a war pilot.
35. There is none.
36. Lacking in imagination. Confidence, but not over-confident.
37. Good eye for judgment and common sense.
38.
39. Cool judgment.
40. "Guts" and a sound head.
41. To be a sound pilot and to have "gut."
42. Guts.
43. Good health, confidence, and nerve. He should be steady. Know how to enjoy himself without over-doing it. To be a stunter he should know as little about machines and engines as possible. Good sportsman, with public school training. A colonial or outdoor life. Show great keenness in his work. Be always wanting to fly. That he should be a man of either colonial type or a public school boy with a good education and manners—i.e., colonial, public school man, jockey and hunting man, racing motorist and cyclist, cavalry officers.
44. Fitness. Common sense.
45. Plenty of nerve. Lack of imagination, and to be of a type that intends not to be beaten by anything.
46. "Guts."

What are your views on the selection of candidates with regard to temperament, &c.?

1. Should be a sporting man, who has absolute control of his nerves, but he may be highly strung and emotional and sentimental, and a man with determination.
2. Different for all types of pilots required.
3. A certain atmosphere about the man which cannot be defined, but is immediately recognised by an old pilot.
4. I consider that when figures are available a great many men will be turned down at once who would go a certain distance before they proved dud, saving considerable time and expense.
5. As a general rule, select no one showing much eccentricity.
6. Have not given the subject sufficient thought to justify an answer.
7. Cheerful and bright disposition.
8. Good appearance, alert, active, decisive, 20–30 years of age.
9. Young, sporting, healthy.
10. Should be moderately highly strung, with an alert brain, but able to keep cool in an emergency and act with lightning rapidity.
11. Youth, 18–24. Spirited, quick, courageous—not caring a damn for anyone or anything. (My experience very strongly suggests that a pilot should never be persuaded to fly if he is not absolutely fit or desirous of flying. Hucks, for instance, has had a very lengthy experience only made possible by not flying when not so inclined.)
12. Candidates should be young and of a cheery disposition and keen.
13. They should have taken a certain amount of interest in aviation from its earliest days. They should be of a mechanical turn of mind. They should be quick but not nervy. They should have very little fear and a good temper.
14. Should have an engineering bent.
15. Should be a public school boy—used to an open-air life—not a clerk—should be a cavalryman or jockey or hunting man.
16. Bright, cheerful, a thorough sportsman, and keen on his job.
17. A man that is fond of sport should, in my opinion, make an excellent and reliable pilot. A man that is not sharp and alert will never be much use as a pilot.
18. A keen sportsman, not too high-spirited. One who can sum up the ordinary risks of flying without increasing same by silly, unnecessary stunting; fairly good education.
19. Two types: (1) Youth, health, and lack of responsibility for scouts and fighters. (2) Older men, steady nerves, and more cautious for other types.
20. A man who can drive a car well and hold his head in a tight corner should be an excellent pilot. Should be bright, quick, and naturally alert, a man good at swimming and all-round athletics.
21. I consider that the youth who is of an "artistic temperament," or otherwise highly strung, makes a sounder and more accurate pilot than one who possesses mere strength. Yachtsmen seem to make good pilots.
22. I think if the candidate is a sportsman, and in other respects of normal temperament, there is no reason why he should not become a good pilot. Probably the best age is 19–20–21. Lots of pilots of 20 and over will never be stunt pilots owing to imagination or foresight, but they may be exceedingly good, reliable, and steady pilots.
23. Keenness to fly ought to cover everything. If a candidate is genuinely keen he'll do. A steady nerve is most useful.
24.
25. They ought to be of good organic constitution, have good eyes, and be of a cheery disposition.
26. Aptitude for sports best indication.
27.
28. One who is of quiet, steady bearing, with a fair knowledge of motors.
29. Like all games (outdoor), cannot be judged by appearance or first few hours' dual or solo flying.
30. It is hard to say at first sight, but common-sense and coolness should count most.
31. One's will-power must control one's imagination.
32. Strong nerves and a light touch.

33. A man who does not boom himself up.
34. I think it extremely difficult to decide at first appearances, which I have proved to be very misleading in many cases. If a man is not keen on and fond of flying he rarely makes good. Coolness in an emergency and a rapid appreciation of the correct thing to do in an emergency is essential.
35. Young, should have led an ordinary outdoor healthy existence. For war work he should be very ignorant of aeroplanes, but keen enough to watch good flying.
36. (1) Find out whether he is really fond of flying and keen, or whether he joined to get a soft job. (2) Previous service in infantry as a private. The knowledge of engines: (1) Necessary if you don't trust your mechanic. (2) Not necessary if you have a good mechanic you can trust. If you have not got an extensive knowledge of engines and you have a dud engine you go on and don't worry. If you have a knowledge of engines you get wind up.
37. Anyone good at games or a good car-driver will make a good pilot in all probability, but not in every case.
38.
39. He must be coolness personified, but with an ever-present alertness. A bright outlook on everything and always cheery. Honour will make him stout.
40. "Cheery-and-full-of-life" men are the best pupils and turn out well. Excitable people are very often good, but they do not last long as a rule. Even-tempered and patient people are the best, but "health is better than wealth."
41. Good health is essential.
42.
43. He must be good at sports and lead an active outdoor life. Strong nerves and patience.
44. They should be fit in every way. Under 30 years of age. Unmarried. They should not have too much imagination or be of an excitable disposition.
45. To be able to take part in everything and yet keep within limits.
46. (1) Lack of imagination, and (2) endurance.

QUESTIONAIRE—SERIES II.

What is the essential characteristic of a good pilot?

1. To realise danger on the ground but not notice it in the air. Coolness in difficulty.
2. Self-confidence.
3. Keenness and good condition (physically).
4. Coolness, quickness in emergency, and general common sense.
5. Steady head; good constitution; self-confidence.
6. Sporting, and for choice one who has travelled and roughed it.
7. Cool head, confidence, and alertness.
8. Quickness of thought and action.
9. Quick thinker.
10. Keenness and bravery toned with discretion.
11. Sportsmanship and pluck.
12. Level headed, steady, not excitable.
13. Concentration, rapid calculation and decision.
14. A quiet and steady disposition but always cheerful.
15. Good health, a clear head, strong nerves, keenness for excitement.

What are your views on the selection of candidates with regard to temperament, &c.?

1. An apparently nervous man will sometimes make the best pilot; this sort of man is very often only nervous of personality.
2. A nervous temperament does not necessarily handicap a pilot; often it is the reverse. Quickness of thought and lack of hesitation essential.
3. Self-confidence and ability to act on one's initiative.
4. An acceptable candidate should be a man of cheery, equable temperament, tending more towards the "devil-may-care" attitude than otherwise.
5.
6. One who is not too cocksure of himself and gives an impression of knowing overmuch. A shy, nervous man in most cases makes a very good scout pilot, and the man who shows great determination usually makes a heavy-handed pilot. The Colonial is at his best at the age of about 19 to 23, and the Englishman who has done little or no travelling from 23 to 26. The Englishman who has travelled vastly and roughed it makes an exceedingly good all-round man and is probably the best of all.
7. A good selection would be an athletic, outdoor living man, the rougher the game he plays the better the pilot he will make.
8. A volatile temperament is best, but does not last long. Steadiness of nerves is good for pilots during C.B. (counter-battery) shoots, but for others the essential thing is to be quick in appreciating a situation; those who do this on the ground can do it in the air.
9. Moderate smokers and drinkers. Men that go in for all kinds of sports.
10. If a man is keen to fly give him a chance to make good. Some extraordinary types of men make splendid pilots.
11. Select any sportsmanlike public schoolboy, it is then only a question of nerve, as 90 per cent. of men can fly. The best war pilot is nearly always an infantry officer with trench warfare experience.
12. Young—not highly strung—with as little imagination as possible.
13. A new pilot should always be ready to take advice, always wide awake, temperate in everything, independent, certain amount of originality.
14. Flying does not suit highly-strung or excitable people; in my opinion, it needs a man who can decide on the instant and who can fly without thinking of actually what he is doing. Anyone who can judge distance well would make a good pilot.
15. The most successful seem to be those who are not too young—steady, ready to act without thinking first, and a good sporting instinct.

THE PHYSICAL AND PSYCHOLOGICAL ASPECTS OF FLYING.

The physical condition should always be compared with the temperament of the individual, but the physical examination should always be preceded by the psychological. *Mens sana in corpore sano* is the ideal type, the healthy mind being the first essential qualification.

If we compare a first-class boxer with an aviator we notice certain similar characteristics. The essential attributes of a good boxer are courage, quickness, good muscular coördination, and ability to anticipate his opponent's intentions so as to deliver his own blow first. Powerful muscles and a large lung capacity are no indication whether a man is likely to be successful as a boxer unless he has the temperament as well.

The possession of a suitable temperament is the criterion of the individual's ability to fly; the possession of a suitable physique is the indication whether he can fly to great heights or whether he will stand the strains and stress of continuous flying. The following examples show that physical fitness without a suitable temperament is no indication of ability to fly. The cases mentioned were all able to pass the routine tests for physical condition, but after a course of instruction in elementary flying were sent by their instructors for a medical examination with statements that they showed no aptitude and recommended them to be withdrawn from instruction as "temperamentally unfit."

Examples of Unsuccessful Canaidates.

1. Second Lieut. W., aged 18, single, clerk. Used to play football for boy scouts on Saturdays. Board school education. As soon as he realised that eventually he would have to fly by himself he showed signs of "nervous breakdown," complained of headache and loss of confidence.
2. Second Lieut. S., aged 18½, single, fitter in engineering works. Played games slightly. Educated at technical school. Loss of confidence when ready for solo.
3. Lieut. J. S., aged 24, single, architect's clerk. Played games slightly. Education fairly good. After failing to pass as a cadet in the R.F.A. he joined the R.F.C. When ready for solo refused on account of fear.
4. Lieut. S., aged 23, married, one child, electrical engineer. Went in for cycle racing. Education poor. Was quite happy in the air as long as the instructor was there, but could not face the responsibility of flying alone. Joined on account of pay and avoiding infantry.
5. Second Lieut. R., single, artist. Games: Nil. Education fair. Dreamy, emotional, artistic. Showed no aptitude to fly.
6. Second Lieut. M., single, purser's assistant 4½ years. Games: Nil. Education fair. Stammers. Not keen on flying. Joined because he was always asked why he was not in the Army. Showed no aptitude.
7. Second Lieut. W., aged 22, single, clerk. Games: Slight. Education fair. Had a "breakdown" before the war. Began to stammer on active service. Admitted to hospital with laryngitis. During his stay a crashed pilot was brought into the ward and he fainted. Subsequently gave up flying.
8. Second Lieut. P., aged 19, single, at school. Played games considerably. Education excellent. Hereditary nervous temperament. Stammers when excited. Hypochondriac. After 18 hours dual showed no aptitude.
9. Second Lieut. T. D. W., aged 18, single, chartered accountant apprentice. No games of consequence. Higher grade school education. Crashed on first and second solo; was able to obtain his elementary instruction certificate at the School of Instruction, but stated that he now has a sense of impending disaster, which suggests a breakdown before long.

All the above cases passed the physiological tests for respiration, circulation, balance, &c.

Examples of Physically Unfit Men with a Suitable Temperament who were Successful Aviators.

1. Lieut. W. A pilot of great determination, resolution, and strong personality, alert, cheerful, and optimistic. Physically he was muscular, plethoric, cyanosed complexion, and short-winded. When I knew him he was flying regularly as a ferry pilot, but stated that he disliked flying over 3000 feet.
2. Lieut. T. An alert, happy-go-lucky schoolboy type. Fond of dancing and rag-time, has a keen sense of humour, is inclined to be obstinate, very keen on flying, and very jealous of his reputation as a pilot. Apparently possesses little or no imagination and knows little of the details or construction of engines or aeroplanes. Physically he is "borderline" on tests. In addition he is a confirmed mouth-breather, and there is a systolic murmur at the apex of the heart, which is displaced downwards. His present occupation is a test pilot (Camels, D.H.4 and D.H.9). He flies every day at an average height of 10,000 feet, and usually rolls, loops, and spins. He flew a Bristol fighter to 21,000 feet under my own (T. S. R.) personal observation and showed no signs of distress.
3. Lieut. C. An alert, cheerful type. Flew 60 hours in France as an observer and was successful in various combats. Showed considerable aptitude in flying. Physically he failed to pass the tests.
4. Second Lieut. M. C. Cardio-vascular debility. Cyanosis. Cold hands and feet. Distress at heights. Flying regularly as a ferry pilot.
5. Second Lieut. Y. Early phthisis. Flying to France several times a week. Has to be kept under careful observation and given a rest occasionally.
6. Second Lieut. J. Hypertrophy and dilatation of heart; occasional attacks of syncope. Fainted in the air on two occasions. Is now an instructor. Previously has been a ferry pilot and test pilot.
7. Second Lieut. B. Cardio-vascular debility. History of malaria and dysentery. Fainting at heights. Flying in India.

MARRIAGE.

The following figures show the percentage of married and single who qualified in elementary flying from Sept. 29th, 1917, to Jan. 24th, 1918, at a School of Instruction:—

Total number of pupils, 369; married, 36; single, 33.
Number of single men who failed to qualify, 13 = 4 per cent.
" married " " " 6 = 17 "

Table II. shows that the married man takes longer to learn to fly than the single man. It will be noticed that the dates of arrival and departure of the married men are compared with those of a single man who qualified in the same month, as the number of flying hours per day varies from month to month according to the weather. The age of the married men was probably greater than the single, but they were all within age-limit standard.

TABLE II.

(A) Date of arrival at school of instruction. (B) Date of departure.

OBSERVATION OF THE CHARACTERISTICS OF UNSUCCESSFUL PUPILS UNDER INSTRUCTION.

We desire to draw attention briefly to the following physical disabilities which are associated with temperamentally unfit pupils: (1) Stammering; (2) minor defects of vision; (3) adenoids, or nasal obstruction; (4) poor peripheral circulation; (5) loss of tone (soft and flabby muscles, moist and cold hands, pale complexion, stomach splash, &c.). We do not suggest that any one of these defects necessarily disqualifies a pilot, but that their presence indicates a tendency to an unsatisfactory temperament.

The temperament of the unsuccessful pupil is the antithesis of that we have previously described, but we will enumerate the main points:—

1. *Early life.*—Did not play games at school to any extent, and seldom went in for sports. Amusements usually indoor.

2. *Occupation.*—Usually clerical or sedentary.

3. *Age.*—Candidates of 30 years or over were hardly ever successful.

4. *Marriage.*—The married men are rarely successful, and if they do qualify, rapidly suffer from "nerves."

5. *Object in joining the Flying Service.*—Usually on account of pay or else to avoid the infantry. Do not show any enthusiasm about flying.

6. *Mentally.*—They are sluggish, dreamy, emotional, self-conscious, lacking in sense of humour, and devoid of that elusive quality commonly known as "guts."

7. *The family history* is often suggestive. One of our unsuccessful pupils inherited a nervous temperament from his mother; another, who was lacking in judgment and also an alcoholic, was the child of an epileptic; a third gave a history of his father committing suicide; and so on.

8. *Whilst under instruction* the unsuccessful pilot flies erratically, grips the control lever much too rigidly, makes the necessary movements jerkily, over-rectifies all errors, and to the onlookers gives one the same impression as a badly ridden horse. In short, he does not possess "hands."

THE STRAIN AND STRESS OF FLYING.

BY LIEUT. E. G. MANUEL, R.A.F.

The prospective pilot, whilst a pupil under instruction, very quickly shows whether he has aptitude for flying when he goes up for his first solo. It is then, properly speaking, that the strain begins. The first solo is a great strain, but in some respects is not so great as are the second and third; firstly, because the pupil is keen to do his flight, and, secondly, he has not before realised the unconscious confidence he has in the presence of his instructor, and the utter loneliness he feels when in control of a machine of which he knows very little.

The strain of ordinary straightforward aerodrome flying, to the qualified pilot, consists chiefly in the liability to engine failure and the fear of crashing the machine on landing. In cross-country flying the strain is much greater; there is still the fear of engine failure, which, in this case, may occur over unsuitable country, with the certainty of a crash. Added to this the pilot has to find his way, try to read a map, work his controls, and keep an eye on the compass. In addition he may meet unfavourable weather, and be given the choice of flying at a dangerously low altitude or going above the clouds and frequently getting lost, with the added anxiety that in the event of engine failure he cannot see the kind of country he is over until at too low altitude to pick on suitable landing ground. In cross-country flying fog or ground mist is the pilot's greatest enemy. Unless exceptionally lucky he is bound to lose his way, and in the event of a forced landing is absolutely helpless and perfectly certain to crash into some obstruction.

The strain on the single-seater pilot is greater than on the two-seater pilot, as, in addition, he has a sense of loneliness. Irrespective of the type of machine, this is accentuated at heights in the majority of cases. Inability to stand heights is not infrequently due as much to psychological causes as to distress caused by insufficient oxygen.

Flying Overseas.

There is certainly a cumulative strain on the pilot, greater than any other form of aviation. Duties overseas consist of: (1) artillery observation; (2) offensive and defensive patrols; (3) trench strafing; (4) night bombing; (5) day bombing; (6) long reconnaissance and photography.

One of the greatest strains on the pilot's nerves is when he sees one of his friends go down in flames, or, after arriving at the mess, he learns that so-and-so is missing. When this occurs with monotonous regularity it is very hard for the pilot to maintain his mental equilibrium. There is no branch of the service where losses are more keenly felt.

In long reconnaissance and bombing raids the chief anxiety is again one of engine failure and forced landing in enemy country, or getting detached from one's flight for some reason or other and becoming a comparatively easy prey to a group of hostile machines. Probably the strain that tells most on the pilot is the constant anti-aircraft fire. He begins by disliking it intensely, has a period of complete indifference, followed by an obsession that he has escaped so long that he must be hit at any moment. Though this strain is felt by all pilots, whatever their duties, it is most marked in those on fighting machines, two-seaters or scouts. This work usually consists of patrolling a definite strip of enemy country for a period of two to three hours. They have to prevent any hostile machine from crossing the lines and engage in combat any group of enemy machines they may come across. Whilst the chance of a fight is eagerly welcomed as a distraction, it frequently happens that no combatants appear for long periods, and the pilots are left without any occupation to distract them from the constant anti-aircraft fire, which, from the fact that the machines are constantly passing and repassing the same strip of territory, allows unrivalled opportunity for good shooting.

During the last few months great attention has been paid to low flying (at 500 feet or less) attacking the enemy with machine-gun fire in his trenches, whilst marching along the roads, in rest billets behind the line, &c. The strain of this kind of flying is great, as the machine is subjected to a tremendous amount of machine-gun fire, and, when working in conjunction with an infantry attack, is continually in, or very near, the barrage fire put up by the artillery. A hit that might only temporarily disable the aeroplane and give the pilot time to recover from it flying at a height is probably fatal when so near the ground.

THE Glasgow University Unionist Association have decided to invite Sir Henry Craik and Sir Watson Cheyne, the present Members for Glasgow and Aberdeen and Edinburgh and St. Andrews Universities, to become Unionist candidates for the new constituency of the four combined universities at the next election.

MIDDLESEX HOSPITAL.—The opening of the winter session of the Medical School will take place on Tuesday, Oct. 1st, at 3 o'clock, when Lieutenant-General T. H. J. C. Goodwin, Director-General Army Medical Service, will occupy the chair. The prizes will be distributed by the Dowager Countess Brassey, and Dr. C. H. Browning, the director of the hospital's pathological laboratories, will deliver the opening address, the subject being the Importance of Research Work in Connexion with National Health.

SOME REMARKS ON
CHRONIC INTESTINAL STASIS.

BY SIR W. ARBUTHNOT LANE, BART., M.S. LOND., F.R.C.S. ENG.,
CONSULTING SURGEON, GUY'S HOSPITAL, ETC.

FOOD products that are absorbed from the gastro-intestinal tract are carried by the portal vein to the liver. In that organ they undergo a process of purification. Certain organisms or toxins are destroyed or are converted into materials harmless to the tissues through which they are to pass, and are eliminated by the several excretory organs, as the kidneys, lungs, and skin.

The thyroid gland secretes material which acts as a stimulant to the tissues and keeps their metabolism working at a normal rate. This substance has been obtained in a pure form at the Mayo Clinic, and is described in the Transactions of that clinic for 1917 by Mr. E. C. Kendall. This discovery is an admirable example of the excellent research work carried on in that institution. The adrenals and the pituitary gland also act in controlling certain tissue changes by means of their secretions. The spleen produces a proportion of leucocytes and destroys a number of effete red corpuscles. Many other instances of specific glandular activity will readily occur to the reader.

Effects of Deleterious Materials on Liver.

If material of a deleterious character greater in quantity than the liver can deal with is absorbed by the radicles of the portal system, certain changes must result in all these tissues, or rather the tendencies to such changes must exist.

I have demonstrated in the anatomy of the labourer that the habitual repetition of the tendency to change results in the fixation of the change, and later in its exaggeration, so that a condition is finally obtained which differs completely from the normal and is perfectly characteristic of the occupation of the individual. In consequence the skeleton becomes unable in many instances to perform its original normal function. I refer, for example, to the ankylosis of the vertebræ and of the costo-vertebral joints in the coal-heaver. I might multiply illustrations indefinitely.

The excessive strain on the function of the liver cells, whereby poisons are rendered harmless, must after a sufficient time in a similar manner result in damage to the liver, so that it is no longer able to perform many of its normal functions efficiently.

Here I would remind the reader that in the labourer every change that is developed in the pursuit of his occupation with the object of improving his usefulness for his special function tends to shorten his life. This is also illustrated by the bands which develop about the intestines in the line of strain. At first these help to support the intestines and to obviate their prolapse. Later they form obstacles to the free passage of material through the portion of the bowel to which they are attached. I believe that a similar effort on the part of the cells of the liver to meet the habitual flooding with deleterious matter brings about a change in them that is at first advantageous and enables them to perform their increased functions more efficiently for a time. This, however, sooner or later results in their undergoing degenerative processes which render them less and less efficient.

Just as every change, which the skeleton of the labourer undergoes in order to accommodate itself to its surroundings, tends to shorten the life of the individual, so do all the changes, which the organs undergo to meet their surroundings in association with and dependent upon those in the gastro-intestinal tract, tend to shorten life. Such changes in the organs are classified as diseases.

Effects on Other Organs.

I do not know whether bacteria and toxins from the intestine reach the systemic circulation through the thoracic duct and so escape destruction in the liver, though I am aware that they reach the regional lymphatics, since Dr. N. Mutch has obtained bacteria from that source on many occasions in cases of intestinal stasis.

The deleterious materials, whatever they are, which pass unchanged through the liver and get into the systemic circulation damage every tissue in the body; none can escape their baneful effect. The liver also suffers through its nutritive supply from the hepatic artery, and its usefulness is still further depreciated in consequence.

The impure blood would appear to act in a similar manner on the thyroid gland. Clinically, in a typical case of intestinal auto-intoxication the thyroid gland at first enlarges as if stimulated to excessive function. As time goes on it steadily diminishes in size till the isthmus can no longer be felt by the finger. Associated with this atrophy symptoms develop that suggest a defective function of this gland.

It would seem fair to argue by analogy that the adrenal and pituitary glands behave in a similar manner in their attempt to meet the disability that results from the supply to their tissues of blood contaminated with deleterious products. The evidence of the defective action of the adrenal is suggested by the very typical pigmentation of the skin which develops in chronic intestinal stasis. I have described on many occasions the deleterious action of the impure blood on many others of the tissues in the body.

How the blood-forming organs behave we can judge by the anæmia which is always associated with this condition sooner or later. This anæmia would appear to be the result of flooding of these organs with impure blood which depresses their functional activity.

The kidneys suffer from the filtration through them of irritating products, and changes take place in consequence after a time. The evidence that these degenerative processes are due to the presence of toxic material in the blood is shown by the fact that all manifestations tend to disappear with striking rapidity when the source of fouling of the blood stream has been removed.

Secondary Infections.

Owing to the lowered resisting power of the tissues to the entry of the organisms foci of infection are readily developed. The septic products of such infection are carried directly into the systemic circulation and are not filtered through the liver. Consequently the effects which are exerted on the body by these secondary infections are much more harmful. This can readily be illustrated.

A patient suffering from intestinal auto-intoxication becomes affected by rheumatoid arthritis. The progress of this disease may be slow till the additional development of pyorrhœa occurs. The absorption of the toxins from the diseased gums into the blood stream at once exaggerates in a remarkable manner the rate of progress of the rheumatoidal condition. The curing of the pyorrhœa by local application or by the unnecessary removal of the affected teeth immediately effects a very marked improvement in the condition of the diseased joints. This is sometimes so apparent as to lead casual observers to assume that the rheumatoidal infection was consequent solely on the infection of the gums, since they do not realise that both infections have a common causal antecedent in the lowered vitality which results from chronic intestinal stasis. At the same time, it shows very clearly how one secondary infection may accentuate another and how necessary it is to search for such infections. Especially is this the case when the infecting organism is the same in the two foci.

The freeing of the portal circulation from products of auto-intoxication at once stops the progress of the rheumatoid arthritis and facilitates the rapid and permanent cure of the affected gums.

Another instance of a secondary infection of the alimentary canal is that which results in pernicious anæmia, a disease apparently due to hæmolysis produced by an unknown specific organism.

Changes in Liver, Breast, and Pancreas.

Not only is the liver tissue damaged by an excess of one of its functions and by the impure blood supplied for its nutrition through the hepatic artery, which also contains toxic material, but its tissues can also be injured through the ducts which permeate every portion of its structure. Dr. Mutch has demonstrated very clearly by cultures made from cases of chronic intestinal stasis operated on by me that the whole length of the small intestine, including the duodenum, often contains infective organisms, and there is no doubt whatever that these organisms may extend along the ducts of the liver and pancreas and produce changes in the walls of the ducts and in the cells and connective tissues of these organs. I suggested the probability of the existence of this sequence in my earliest papers on stasis, and it is satisfactory that these hypotheses have received such definite confirmation from Dr. Mutch's extensive and elaborate researches.

Now let us consider the conditions or changes that develop in the liver in consequence of the infection of its ducts, from the flooding of its tissues with impure blood through the hepatic artery, and from the excessive demand made upon it by the abnormal quantity of toxic materials and of organisms which are carried to it through the portal circulation. That definite and important degenerative changes must result sooner or later in varying degrees from these influences is undeniable. At the same time, we are not sufficiently well informed to be able to determine how each of these agents acts. We know enough to recognise some of the effects.

For instance, we are very familiar with cholecystitis and the associated changes in the larger ducts of the liver. We also know that gall-stones are produced by infection of the gall-bladder, and are sometimes formed in the ducts of the liver. Later results are the blocking of the cystic duct, the common bile duct, and of the intestine by gall-stones, together with cancer of the cystic and common bile ducts, from the irritation produced by the presence of these stones. How far primary cancer of the liver is produced by irritation of the terminal ducts or of the cells and connective tissue by impure blood I am not in a position to demonstrate, though by analogy there would appear to be but little doubt as to the causal association.

I think the various forms of cirrhosis are explicable in the same way. For instance, the distribution of the changes in Hanot's disease suggests an ascending infection of the biliary ducts, while those of portal cirrhosis appear to be due to toxins reaching the liver through the portal vein.

In every advanced case of chronic intestinal stasis the presence of induration of the pancreas can be demonstrated, and there is no doubt that carcinoma develops in these fibrous patches. I showed many years ago that it develops in the breast, which undergoes similar changes from intestinal auto-intoxication. I notice that since I described this sequence as occurring in the breast a number of others have observed and described it. Originally the suggestion was received with ridicule.

It is now generally recognised that traumatism is a necessary causal factor in the development of cancer, though it is probably not the sole factor. Traumatism as a determining factor can readily be demonstrated in all carcinomatous ulcers of the gastro-intestinal tract, whether produced by pressure or impact, as in ulcers of the tongue, pylorus, and large bowel, or by the exercise of excessive strain, as in ulcers of the lesser curvature of the stomach. In cancer of the breast and pancreas the traumatism is apparently effected by the damage sustained by groups of cells from contraction of the fibrous tissue about them, this formation of fibrous tissue being the result of auto-intoxication. It is probable that a similar change due to the same cause antedates the development of cancer in the liver, but this cannot be demonstrated in the same clear manner as in the breast and pancreas. The calculi which form in the pancreatic ducts owe their origin to septic infection, as in the case of the biliary calculi.

Thyroid Gland.

I have already pointed out that in the earlier stages of stasis the thyroid appears to enlarge as if stimulated to perform its function more efficiently. Later it becomes small and hard. That is what one would expect to happen on general principles. McCarrison[1] has demonstrated that the flooding of the intestine with certain fæcal products causes goitrous changes; that these changes disappear if the supply of these products be stopped and if the patient be treated with an intestinal antiseptic; and that these goitrous changes are influenced favourably by the use of such vaccines as tend to sterilise the contents of the small intestine. Also, that a similar result follows the removal of the intestinal infection by operation.

It would appear reasonable to conclude from McCarrison's experiments and observations that—as goitre results from the contamination of the water- or food-supply with ordinary fæcal matter and can be cured by the cessation of the infection—goitrous conditions as they exist among people whose food is not contaminated by sewage products are consequent on the absorption from the small intestine of material which has become contaminated by fæcal organisms which have extended up to its stagnating contents from the large bowel. This is the view that I have put forward for many years, and which has received ample confirmation from McCarrison's elaborate researches. In a number of cases of goitre in its several varieties occurring in patients whose food could not have been infected by sewage products and in whom radiography demonstrated the presence of well-marked stasis, and cultures taken from the contents of the small intestine at varying levels yielded organisms, the freeing of the ileal effluent by colectomy or by simpler means had resulted in the restoration of the thyroid body to its normal size.

The results of these operations differ materially in the various forms of thyroidal affections. While the simple goitrous enlargement yields rapidly the size of the adenomatous thyroid diminishes more slowly. The exophthalmic thyroid always benefits in that a remarkable improvement takes place in the patient's health, weight, and happiness, although the special manifestations of the disease do not always disappear completely. Instances of the results of some of these operations are described by Dr. Mutch in "The Operative Treatment of Chronic Intestinal Stasis" (fourth edition).

[1] THE LANCET, 1913, i., 223.

THE DIAGNOSIS AND TREATMENT OF MALARIA.

SOME PRACTICAL HINTS FOR PRACTITIONERS AT HOME, WITH NOTES ON 750 CASES TREATED IN SCOTLAND DURING THE PAST YEAR.

BY D. G. MARSHALL, M.B., C.M. EDIN.,
MAJOR, I.M.S.; CONSULTANT IN MALARIA, SCOTTISH COMMAND.

SINCE the beginning of the war there has been a constant stream into this country from various parts of the world of men suffering from malaria, and this is likely to continue for some years, even after the end of the war. Most of these cases are, or will be, treated in military hospitals, but a very large percentage develop attacks while on leave or after leaving the Service, when they have to be attended by general practitioners. The following notes are written in a plain fashion, devoid of unnecessary detail or complex statistics, in the hope that they may prove of help.

Incidentally these notes may present points of interest to those engaged in the treatment of large numbers of malaria cases, the system of treatment and the results obtained serving as a series of "control" observations for comparison with the results when other and more varied systems have been adopted. Of the 750 cases only one ended fatally, death being due to blackwater fever; the majority returned to duty, only a small percentage, chiefly elderly men broken down by service and the after-effects of malaria, being discharged the Service. Under the system of treatment adopted *relapses* only amounted to 10 per cent. of cases in hospital, or, including those known to have relapsed after discharge, 15 per cent. In the vast majority of relapses rise of temperature only occurred on one day. The attack seldom lasted more than two or three days, these results evidently being due to the efficient administration of quinine.

Diagnosis.

This can only be reached with absolute certainty by finding the malarial parasite in the blood; staining films by Leishman's method is a very simple process, and any medical man who has a microscope with an oil-immersion lens should, with a little practice, be able to detect them; the parasites, however, are often present in very scanty numbers in the peripheral blood, and prolonged search, maybe of several slides, is necessary before a negative diagnosis is made. When microscopic examination is not feasible, thin films of blood on slides or cover-glasses should be made, preferably about six hours after the height of the febrile attack, and sent for examination to some competent authority.

In the absence of facilities for microscopical examination, consideration of the following points will be found useful in arriving at a correct diagnosis.

History of previous attacks.—This is often of great assistance, the patients themselves practically making the diagnosis; a misleading feature is that patients often assert that though they have served for long periods in malarious countries they never suffered from malaria. Probably they

had slight attacks which passed unnoticed or contracted the disease on the journey home. Several cases of this kind have come under my notice.

A colonel who had not been on the sick list during two years' service in Salonika developed typical malaria three months after returning home.

Another, a senior officer of the I.M.S., who vowed he had not suffered from malaria for ten years, developed a temperature after an operation; it was supposed to be influenza, but examination showed the presence of large numbers of malaria parasites in the blood.

Since writing the above an interesting report of two fatal cases has been published. Both men had served abroad; neither had a history of previous malaria. One was diagnosed and treated as influenza, or "P.U.O."; the other was sent to a fever hospital as a case of typhoid.

Nature of attack.—What the old British soldier in India used to describe as "fever and ague," the presence of a distinct cold and hot stage, is fairly typical, but two very important points must be borne in mind. In the æstivo-autumnal or "malignant" type of fever the cold stage is not very marked; there may even be an absence of rigor. The temperature in the hot stage is only moderately high; it is more apt to become remittent in type; this is the kind of case often wrongly diagnosed as enteric.

On the other hand, in old malarials with a temperature due not to malaria but to other causes, as septic infection, syphilis, &c., the attack is apt to assume the character of a typical malarial attack—a cold stage, with severe rigor, rapid rise of temperature, subsiding in the course of a few hours, but recurring daily. A man recently admitted with a diagnosis of malarial relapse was found to be suffering from cerebro-spinal meningitis, which ended fatally in three days.

It may be mentioned here that attacks of this nature are often set up in persons who have previously suffered from malaria by surgical interference, especially in connexion with the genital organs, as passing a catheter on a man or a uterine sound in the case of a woman. If any operation is necessary it is advisable to keep the patient under the influence of quinine prior to and for some days after the operation.

Periodicity.—This is one of the most marked features of malaria. In a typical case of benign tertian the attack occurs every third day, in quartan (an unusual form) every fourth day, in multiple infections the attacks may develop every day, in quotidian, they almost always commence with clock-like regularity at about the same hour. This periodicity is also marked in the complications and sequelæ, such as hæmorrhages, exacerbations of skin affections and nervous or gastric disturbances, which may occur at regular intervals, possibly of weeks.

Pulse-rate.—It may be accepted as an axiom that in malaria the pulse curve always follows the temperature curve, and recognition of this fact may help in the differential diagnosis of enteric and other acute febrile affections in which the pulse is not markedly accelerated in the early stages.

Enlargement of spleen.—Except early in an initial attack this is invariably present, and can be recognised by careful percussion and palpation. During an acute attack there is often some degree of pain in the splenic region due to peri-splenitis; in old-standing cases the enlargement may be very marked, extending to, or even past, the middle line.

Effect of large doses of quinine.—In the absence of microscopic examination of the blood this is one of the surest methods; it is very seldem that a case of uncomplicated malaria resists such treatment, but it must be given in adequate doses, at least 30 gr. in the 24 hours; small doses are not only useless, but may be harmful. If a case which appears to be malarial resists such doses repeated for several days some complication should be suspected.

Complications and Possible Errors in Diagnosis.

Complications are many, varied, and apt to be misleading. Space does not permit a lengthy consideration of them.

They occur both during acute attacks and later, all systems of the body being affected. Severe or ambiguous gastro-intestinal symptoms, often simulating appendicitis or dysentery; pneumonia, hæmoptysis, localised and wandering œdema, and other signs of implication of the circulatory system; nervous phenomena, from the extremely fatal "cerebral" form of the disease to obscure signs of peripheral neuritis, are often encountered. Mental disturbance is common, and varies from "confusion" to the more severe forms.

In the case of persons who have been exposed to malarial infection, whether there is a previous history of malaria or not, the probability of malaria being the cause should always be borne in mind when the diagnosis is doubtful. The important point is not to make the mistake of treating local symptoms and leaving the real factor untreated. In reference to this two cases may be quoted:—

1. A lady returning from a visit to India, with no history of malaria, developed fever on the voyage. The case was diagnosed by the ship's surgeon as tonsillitis. After she had suffered with a temperature of 103–105° F. for several days I was asked to see her. When it was suggested to the surgeon that it was a case of acute malaria, he replied, "I never thought of it." The temperature came down and all local symptoms disappeared under quinine, but for some days the patient was in a very critical condition.

2. An officer, who had been treated for some weeks by a civil practitioner, was admitted to hospital last year; owing to attacks of hæmoptysis, pain in hip-joint, &c., the case had been diagnosed as acute tuberculosis and a most gloomy prognosis had been given. Examination of the blood revealed the presence of many malarial parasites. He eventually made a perfect recovery.

Blackwater fever.—This most serious complication so often occurs after the patient has returned to this country that it is worthy of special notice. The onset, which generally follows a chill or is perhaps attributed to a large dose of quinine, is usually sudden, with an initial rigor; there is severe and persistent vomiting, the urine soon assumes the typical "porter"-like colour, is passed in small amount, and there may be actual suppression. On the second or third day, if the patient survives, the skin becomes of an extremely bright-yellow colour. Death may result in the early stage from hyperpyrexia, or later from suppression of urine or cardiac failure.

Treatment.

The following are the routine methods employed in the special malaria wards, Bangour, to which most of the 750 cases under notice have been admitted. This resolves chiefly into the measures to be adopted (1) prior to an attack; (2) during an acute attack; (4) after an attack, to prevent relapses; (4) treatment of complications.

Prior to an attack, especially an initial one, there are often malaise, vague shivering sensations and gastro-intestinal disturbance. It is sound treatment in such cases to administer a dose of calomel followed by a saline aperient, with liberal doses of quinine as early as possible; by these means the threatened attack may be aborted.

During an acute attack careful nursing is necessary. In the cold stage the patient requires, and probably demands, much extra clothing; in the hot stage there is a danger of chill owing to the patient wanting to dispense with what he considers unnecessary clothing; when the sweating stage is past the patient should be carefully rubbed down and provided with warm dry clothing and bedding.

During the cold stage there is often distressing vomiting and severe depression; the vomiting will generally be allayed by sinapisms; in severe cases a hypodermic of morphia may be necessary, but this and the use of alcoholic stimulants should be employed with caution for fear of developing a habit.

During the hot stages there is generally intense headache, with a flushed face and marked photophobia, the patient, even in benign cases, lapsing into a state of semi-coma, the temperature rising to perhaps 105–106° with a correspondingly quick pulse. In ordinary cases cold affusions, the use of an ice cap, with a dose of aspirin and caffeine will relieve the headache. In the severe "cerebral" forms it may be advisable to administer quinine intramuscularly or intravenously, but this is seldom necessary at home. In the treatment of the 750 cases under notice neither of these methods has been employed in any case.

When the urgent symptoms have subsided and the temperature is falling, give 15 gr. of quinine and repeat the dose twice daily, giving a dose on the following day two hours before the attack is due. Continue this for three days or until the attack is definitely checked. In malignant cases the hot stage is often so prolonged that the temperature assumes a remittent type and may not come down to normal for several days; in this case quinine must be given irrespective of the temperature.

The acute attacks, if properly treated, usually subside in 2–3 days, and then the treatment for the prevention of relapses must be adopted.

Prevention of Relapses.

The means to be adopted with this aim are: (1) general treatment of patients and (2) administration of drugs.

General treatment is most important. Chill being one of the most common causes of relapses, patients must be well clothed and carefully advised to avoid chills. On the slightest sign of discomfort or shivering after exposure they should take at least 10 gr. of quinine. A bracing climate is desirable, preferably at a fair altitude. The special wards at Bangour are about 500 feet above sea level, and to this the satisfactory results in the treatment there are to a great extent attributable. The whole muscular system, including the heart muscle, suffers loss of tone in malaria. This loss is not likely to be made good by keeping patients lolling about the wards in a listless manner day by day. After an acute attack patients are kept in bed for a week, they are then given graduated exercises, culminating in the third week with route marches of 2 or 3 miles morning and afternoon or work in the garden or workshops. As soon as possible the fullest possible diet is given, occasionally supplemented by an issue of beer or stout.

Drugs.—After an acute attack the patient is put on 20 gr. of quinine per diem for a week, 10 gr. night and morning after a meal, for the next week 5 gr. night and morning, and for the third 5 gr. after breakfast. As a rule, they are discharged at the end of this period, but if kept in hospital

they are put back to the 20, 10, 5 gr. system. On discharge to duty arrangements are made by which it is ensured that the man will continue the prophylactic use of quinine for two months. In hospital the quinine is administered in the form of hydrobromide, with a small quantity of dilute hydrobromic acid; this salt causes less discomfort or cinchonism than any other.

Excepting in a few cases when it has been deemed advisable to administer it by the rectum, quinine is always administered by the mouth, the frequent reports in the medical journals of inability to give it by this means being due to faulty methods.

If the patient complains that quinine causes sickness or other discomfort, what can be done? Give 10 minims of laudanum half an hour before the quinine. Give it in "compressed" tabloid form or cachets instead of in solution, or in fractional doses—e.g., instead of giving 10 gr. morning and evening give 2 gr. every two hours, and so on until the desired amount has been taken.

In the few exceptional cases where the patient is absolutely unable to take quinine or it fails to check the fever methylene blue forms a very efficient substitute. It is given in the form of pill, 3 gr. with 1 gr. extract of hyoscyamus three times a day. There are many impure samples on the market which are likely to cause bladder irritation, tenesmus, and other discomfort. Methylene blue (pure medicinal) should always be prescribed. It has on many occasions been found to prevent relapses when quinine, by the mouth, intramuscular or intravenous injections, in other hospitals has failed. In cases with a history of blackwater fever it is always used in preference to quinine.

Quinoidin has been tried in many cases with satisfactory results; it causes less discomfort than quinine, and has the advantage of being much cheaper. Galyl is said to afford good results in obstinate cases, but its employment has not so far been found necessary. When the gastric irritation usually associated with an acute attack has subsided the patients are placed on a tonic, as follows:—

℞ Ferri et ammon. citrat... ... ... gr. x.
Liq. arsen. hydrochlor. ... ... m iii.–vi.
Tinct. nucis vomicæ ... ... m v.
Aq. chloroformi ... ... ad ℥ i., t.d.s.

The combination of arsenic and quinine often prevents relapses when quinine alone, even in large doses, fails.

The Treatment of Complications.

Blackwater fever.—The indications for treatment are: (1) Restrain the temperature, (2) promote free secretion of urine, (3) arrest vomiting, (4) maintain action of heart.

1. The ordinary antipyretics should not be employed, careful sponging is generally sufficient.

2. Keep the patient warm, apply hot poultices to the loins, give plenty of diluents—tea, coffee, barley, Vichy, or soda-water; ordinary diuretics are contraindicated, but the following (Sternberg's) mixture is useful:—

℞ Sodii bicarb. ... ... gr. x.
Liq. hydrarg. perchlor.... ... ... m xv.
Aquam... ... ... ad ℥ i.

given every two hours for the first day and every three hours afterwards until the urine clears. If suppression threatens or supervenes, renew poultices frequently, with dry cupping over the kidneys, and administer normal saline by enemata, subcutaneous infusion, or intravenously, with strophanthus by the mouth. Pilocarpine is contraindicated.

3. The ordinary methods—sinapisms, ice, champagne, &c., often fail. Morphia hypodermically is often efficacious and also diminishes the general distress. The best treatment in severe cases is counter irritation of the vagus by painting liquor epispasticus over the course of the nerve on the left side of the neck; this often arrests the vomiting in an hour or two when all other methods have failed.

4. The usual heart stimulants may be employed; strophanthus is better than digitalis; the use of alcohol except in the form of champagne is inadvisable.

There is generally hepatic congestion with constipation; a dose of calomel and an aperient should be given early in the attack.

It is a much disputed question whether quinine should be given or not. Founded on Bastianelli's rule the following lines of treatment are recommended. 1. If parasites are found in the blood during or after an attack the bihydrochlorides or hydrobromides should be given, but in fractional doses; the ordinary sulphate should not be prescribed. 2. If parasites are absent do not give quinine. 3. If in doubt—e.g., if a thorough examination of the blood is not possible, avoid quinine.

In the treatment of other complications it must be remembered that they are in great measure due to malaria, and the administration of quinine should never be neglected. It is often found that in persons returning from malarious countries affections which have resisted all other forms of treatment for long periods yield readily to quinine.

NOTES ON THE SYMPTOMATOLOGY AND MORBID ANATOMY OF SO-CALLED "SPANISH INFLUENZA," WITH SPECIAL REFERENCE TO ITS DIAGNOSIS FROM OTHER FORMS OF "P.U.O."

BY E. RIVAZ HUNT, M.D. CANTAB., M.R.C.P. LOND.,
TEMPORARY CAPTAIN, R.A.M.C.

THE recent outbreak of what appears to be a new form of "influenza," so-called, has greatly added to the number of cases admitted to the base hospitals with the provisional diagnosis of "P.U.O.," and some months' experience in the medical wards of a large base hospital in France has suggested to me that it would be useful to attempt to classify the chief diagnostic features of some of the principal conditions which are admitted to hospital with this diagnosis.

The term "P.U.O.," although useful and in some cases necessary, is too loose to be wholly satisfactory. Moreover, a more exact diagnosis is desirable, both from the point of view of prophylaxis and, if necessary, isolation, and also for the purpose of prognosis as to the probable duration of the patient's unfitness for military service.

Certain of the conditions liable to be included under this heading have but to be remembered to be excluded in the majority of cases by appropriate clinical or bacteriological examination. Among these may be mentioned (1) malaria; (2) *Bacillus coli* infections, particularly coli bacilluria; and (3) malignant endocarditis. But a smaller group remains, comprising (4) the trench fevers; (5) the enteric group, including typhoid and paratyphoid fevers, which for my purpose may be considered together; (6) the influenzal group, including true influenza, and the recent epidemic, which in the present condition of uncertainty as to its bacteriological causation, may be provisionally termed "Spanish influenza"; and (7) certain aberrant cases of cerebro-spinal meningitis.

Symptomatology.

The symptomatology of "Spanish influenza" is characteristic, and in view of the extreme prevalence of this disease at present it will be useful first to consider in some detail the principal features of this complaint as seen in France, considering *en passant* the various points which serve to distinguish it from other diseases closely resembling it.

The *incubation* period appears to be short, about 3–4 days. The mode of *onset* is characteristically sudden. A patient may be at work in his usual health in the morning and in the evening he may be in hospital with a temperature of 102°–104° and presenting the appearance of acute illness. The earliest symptoms are usually shivering, pains in the limbs and back and very severe headache—generally, but not invariably, frontal in situation—and sore throat, and in almost all cases an irritating severe cough is also complained of.

The appearance in most cases is quite characteristic. The patient lies curled up in bed in a drowsy condition, with flushed face and injected conjunctiva, but there is little coryza, and physical signs, in the early stages at any rate, are remarkable by their absence. The facies, apart from the absence of coryza, very much resembles that of a measles patient a day or so before the appearance of the rash.

Although severe sore throat may be complained of, little can be seen in the throat beyond some general injection of the fauces, but in some cases œdema of the uvula or slight degree of tonsillitis is present. Severe and irritating dry cough is usually present, but there may be no discoverable physical signs in the lungs at first. On the other hand, some coarse rhonchi may be heard all over the larger bronchial tubes, or a few crepitations may be heard at one or both bases. In other cases there is an early generalised bronchitis, and in some few instances a dry pleurisy, particularly in the left axilla, may make its appearance almost at the onset.

A small percentage of patients develop serious *pulmonary complications*, and the pneumonia arising in these cases presents several distinctive features. It is of a mixed lobar and broncho-pneumonic type. Several large patches of consolidation may be found, but not as a rule at the extreme base of the lung. Favourite situations appear to

be in the axilla, or in the middle third of the lower lobe. A remarkable feature is the not infrequent presence of well-marked ægophony without other signs of fluid over the consolidated area. The very loud tubular breathing and crepitations, together with the increased vocal resonance and the presence of the signs of more normal lung tissue below the patch, suggest that this ægophony is due to a very thin layer of purulent exudation over the pneumonic patch, shut off by pleural adhesions, and thus prevented from gravitating to the lower part of the pleural sac. This is confirmed by the post-mortem findings.

In some of these influenzal pneumonias the toxæmia is severe, and death rapidly ensues from acute heart failure. These cases frequently present an appearance very similar to that of a patient suffering from purulent bronchitis. The colour is a curious bluish tint, suggesting at first sight that he is suffering from extreme right heart failure, but physical examination of the heart and pulse does not confirm this, and the condition appears to be due to extreme toxæmia rather than to any mechanical embarrassment of the right heart. In other cases not quite so acute œdema of the lungs supervenes, large quantities of semi-purulent sputa are expectorated, but the patient dies from heart failure secondary to asphyxia.

The *heart condition* of a very large proportion of these cases of "Spanish influenza" is interesting. Without any marked alteration in the size of the heart as discovered by physical examination, and with the apex beat little if at all displaced, there is a well-marked reduplication of the first sound at the apex or of the pulmonary second sound, which is also frequently accentuated; not infrequently both sounds are reduplicated. In many cases this probably indicates the presence of some degree of myocarditis. It is noteworthy that in a large proportion of cases examined post-mortem here myocarditis was found, and more or less dilatation of the heart was constant. In cases in which a murmur develops and becomes increasingly musical, with displacement of the apex beat, the question of an early ulcerative endocarditis must be considered, and a blood culture and leucocyte count should be done with a view of excluding this condition.

In at least four instances I have seen a *scarlatiniform rash* so closely resembling the rash of scarlet fever that very careful examination was required to decide that we were not dealing with a case of the latter disease. The rash, however, was more markedly patchy in distribution, evanescent and recurrent, and in some cases irritating; and the appearance of the patient's face and throat, together with the absence of the rapid pulse and strawberry tongue of scarlet fever, and also the comparatively low temperature at the time of appearance of the rash, enabled us to exclude the existence of this disease.

One patient, however, who gave a history of another man in his hut having had a rash, was transferred to an isolation hospital, but at a post-mortem examination made after his death from broncho-pneumonia a few days later the appearances presented were precisely those found in other cases of deaths from this influenzal form of pneumonia. The tongue of these influenzal cases is almost invariably dirty and furred, and in some cases there is an offensive, almost pathognomonic, odour of the breath.

The onset of *pyrexia* is very sudden, the temperature rapidly rising to 103° or higher. The duration of pyrexia is generally short, and under appropriate treatment and rest in bed the temperature rapidly falls about the third or fifth day to normal, thereafter probably rising to about 99° on the following evening, but within a week from the date of onset remaining below normal. If the pyrexia persists after the first week it is probable that either some pulmonary complication is present or that the diagnosis of influenza must be reconsidered, special attention being given to the possibility of the case being one of the enteric group.

The *pains* of this type of influenza are very characteristic; they are referred almost invariably to the muscles and soft tissues, and to a less extent to the joints rather than to the bones themselves. The most common sites of pain are in the muscles of the thighs and calves, the lumbar muscles and muscles of the back of the neck, and to a less extent the knees and ankle joints. The headache of influenza has already been referred to. In a very large proportion of cases it is frontal, in some cases occipital, and in a few referred to the vertex. The headache is in some cases very persistent, continuing for some days after the patient's temperature has fallen to normal, and is almost invariably extremely severe at first. The pains differ considerably from those of trench fever; in the latter disease the pains are most frequently referred to the bones themselves, particularly to the inner and outer edge of the tibiæ, and the bones are often very tender to palpation. The acute nocturnal exacerbations of the pains are more marked in trench fever than in influenza.

The pains of the abdominal group of influenza cases may arouse the suspicion of appendicitis. They are, however, more general, although frequently referred to the lower part of the abdomen. There is, however, little or no muscular rigidity, and the tenderness to deep palpation is not more marked in the right iliac region than in the left. The pain does not tend to become localised and the fever and pulse-rate do not indicate a progressive lesion.

There is a group of cases admitted with occipital headache and pain in the neck closely resembling cases of cerebro-spinal meningitis, but, as a rule, the rigidity of the neck is much less marked. In some of these cases the diagnosis is rendered more puzzling by the presence of what I may describe as a "spurious" Kernig's sign—i.e., it is impossible to say that Kernig's sign is absent, although it is more of the nature of a "clasp-knife rigidity" than a true Kernig's sign. Lumbar puncture may, however, be necessary to exclude cerebro-spinal meningitis, when, although the fluid may escape under high pressure it is clear and does not present the characteristic cytological features of the latter disease.

A *blood count* is of great value in helping to discriminate between the various causes of P.U.O. The trench fevers are usually accompanied by a moderate leucocytosis. Malaria, malignant endocarditis, scarlet fever, and cerebro-spinal fever, as a rule, show a marked leucocytosis. The enteric group is more usually characterised by a leucopenia. In "Spanish influenza" the leucocyte count usually varies between 5000 and 9000 per c.mm.

Very few cases of influenza show a true relapse, and the occurrence of pyrexia relapsing within a few days in a supposed case of influenza suggests the probability of the case being one of trench fever.

I regret that the few cases in which the urine has been examined prevent me from making any observation on this point. I have not touched on the bacteriology of these cases, for at present this aspect of the disease is *sub judice*.

Tabular Summary.

Appended are two tables: (1) a summary of the principal diagnostic points of the commoner causes of P.U.O.; (2) an analysis of the post-mortem findings in 30 cases diagnosed as "influenza" at a hospital base in France during June and July, 1918. For these latter tables and for other valuable suggestions I am much indebted to Captain T. W. G. Shore, R.A.M.C., pathologist to —— Administrative District, France.

TABLE I.—*Summary of the Principal Diagnostic Points of the Commoner Causes of P.U.O.*

Disease.	Mode of onset.	Fever.	Characteristics of pain.	Bacteriological examination.	Blood count.
Malaria.	Sudden	Intermittent as a rule.	—	Parasites in blood.	Leucocytosis.
Coli bacilluria.	Gradual	Prolonged and irregular.	Renal, vesical, or ureteric tenderness.	*B. coli* in urine.	—
Malignant endocarditis.	Gradual or sudden	Constant, prolonged, and irregular.	—	Blood culture may be positive.	High leucocytosis.
Trench fevers.	Sudden	Frequent relapses.	Pains in bones, especially shins.*	—	Mod. leucocytosis.
"Spanish influenza."	Very sudden	Short, rarely relapses, subsides by crisis.	Pain in head, usually frontal and back.†	—	Mod. leucopenia.
Influenza.	Very sudden	Short, subsides by crisis, less acute.	Pain specially in head and back.	Influenza bacilli in sputum.	Leucopenia.
Enteric group.	Gradual	Prolonged, gradual onset, subsides by lysis.	Vague; general.	Widal's reaction.	Leucopenia.
Cerebro-spinal fever.	Sudden	High and irregular.	Headache, usually occipital.	C.-s. fluid cloudy, &c.	High leucocytosis.

* Worse at night; shins tender.

† Also pains in legs, usually muscular, in calves and thighs, continuous all day.

TABLE II.—*Summary of Post-mortem Findings in 30 Cases Diagnosed "Influenza."*

More or less dilatation of heart constant.		
Myocarditis	in 20 out of 30.	
Endocarditis of mitral valves	,, 2	,,
Pleurisy	,, 26	,,
Pleural effusion	,, 8	,, (Generally purulent).
Broncho-pneumonia	,, 27	,, Broncho-pneumonia the rule. Often confluent, less so in later cases.
Lobar pneumonia	,, 1	,,
Confluent broncho-pneumonia	,, 11	,,
Miliary pneumonia	,, 4	,, Miliary or shotty broncho-pneumonia in later cases.
Pus in bronchioles	,, 12	,, Resembling purulent bronchitis, commoner in later cases.

Collapse when present along vertebral border of lung. Emphysema common anteriorly.
Nephritis { Acute in 7 ... ... Kidney as a rule pale—"toxic." / Chronic in 2 ... ... Suppression of urine in one case.
Jaundice in 2.
Spleen generally enlarged.
Pulmonary glands always enlarged.
Liver generally shows some fat.
Pulmonary abscess in 3.
Abscess in brain in 1.
Old tubercle in 7. (Much higher than average in B.E.F.)

OBSERVATIONS ON A CASE OF "LOOSE BODY" IN KNEE-JOINT.

BY PAUL BERNARD ROTH, F.R.C.S. ENG.

Origin of "Loose Bodies."

"Loose bodies" may occur as a result of (1) chronic hypertrophic osteo-arthritis, (2) trauma, (3) chondrification or ossification taking place in hypertrophied joint villi, or (4) the process known as osteo-chondritis dissecans. In the present case, in spite of the history of trauma, the osteophytic formations point strongly to the first of these conditions as the determining cause. It is therefore highly probable that this patient will at some future time again suffer from other "loose bodies" in her joint.

Notes of Case.

Patient, aged 38, was first seen at hospital on Oct. 30th, 1917. Six months previously when kneeling she tried to get up quickly, but could not straighten her right knee because of great pain in it. This pain lasted for a week or ten days, and then gradually disappeared and the knee got well. Since then she has had every other week attacks of sudden severe pain in the knee and inability to straighten it.

On examination there was found to be marked creaking accompanying movement in both knees and slight lipping at the articular margins. The right knee could be completely straightened. To test her story she was told to go home and return directly she had another attack. A week later she stated that she had had another attack on the previous day. On examination there was slight puffiness of the knee, it was hotter than the other, and it could not be completely extended. Radiograms taken the following day by Dr. W. Ironside Bruce were reported on by him as follows: "There is present an arthritis of the knee-joint with + osteophytic formation. There is also present a very nice example of 'loose body' which at the time of examination lies in the *posterior part* of the joint."

On further questioning patient remembered that seven years ago she fell with right knee doubled up; she could not get up by herself, was carried on to a sofa, and had to remain a fortnight in bed, the knee being very much swollen; she did not call in a doctor. Since then the knee had been quite well until May, 1917, when the present trouble began.

Operation (Nov. 19th, 1917).—With the knee lying slightly flexed over a sand-bag an anterior median vertical incision six inches long, with its centre opposite centre of patella, was made through the skin and subcutaneous tissues and deepened until the quadriceps extensor tendon, the patella, and the ligamentum patellæ were reached. Sterile towels were clipped to the two edges of the wound with Kocher's tissue forceps and the skin completely shut off. The patella was next split vertically into two lateral halves with chisel and mallet. With a fresh scalpel the line of cleavage was extended up into the extensor tendon and downwards into the ligamentum patellæ, so that these structures also were bisected mesially into two lateral halves. The two halves of the patella were drawn apart with blunt retractors and the knee simultaneously flexed to a right angle, the foot being kept in contact with the table. The "loose body" was at once seen lying *in front of* the anterior crucial ligament; it was removed with forceps, the knee was straightened, the quadriceps tendon and ligamentum patellæ sutured with No. 4 continuous catgut, and the skin closed with Michel's clips.

Patient made an uninterrupted recovery, no splint of any kind being used during convalescence, and a month later was again radiographed. The radiograms again showed the "loose body" present, and the report stated it to be so. On very careful study of the first radiograms I made out, lying above the shadow of what we had considered in the lateral view to be the "loose body," another much fainter shadow; and in the second radiograms this faint shadow was absent. It was, therefore, clear that originally there were two "loose bodies" present, one of which had been removed, or that the remaining shadow was due to a sesamoid bone in the gastrocnemius.

Remarks.

The following points present themselves for observation.

1. *Route adopted for operating.*—I believe this median patellar route to be the ideal one for operating on all internal disorders of the knee-joint. If used with strict adherence to the rules adopted by Lane in plating bone the risk of sepsis is nil, a splendid view is obtained of the joint interior, and no injury is done to the mechanical power of the joint. Further information as to its great utility may be obtained from the writings of Sir Robert Jones, Mr. E. M. Corner, and from my own paper,[1] in which has been given a list of references.

2. *Differential diagnosis of "loose body" from sesamoid bone in outer head of gastrocnemius.*—I have not been able to find any research done on this subject, and until this case had never heard of any difficulty in coming to a correct decision. It may be taken as a general rule, however, that a sesamoid bone when present is oval in shape when seen from the side with its long axis placed vertically; that it is as dense to the X rays as the densest parts of the femur, tibia, and patella; and that it is situated behind a line joining the most posterior portions of the tibial head and femoral condyles as seen in the lateral radiographic view and well to the outer side of the midline in the antero-posterior view. A "loose body," on the other hand, may be of any irregularly rounded shape, is not as dense to the X rays as the densest parts of the other bones, and may be anywhere in the joint cavity.

In the present case the shadow remaining after operation is circular when seen in lateral view, is as dense as the other bones, is situated almost entirely in front of the line joining the two bones, and in the antero-posterior view shows up quite plainly on the inner side of the midline of the joint—that is, the evidence is largely in favour of it being due to a second "loose body." If such it be, it is causing no symptoms, for since operation the patient has been entirely relieved, and when last seen in April the knee had entirely ceased to bother her.

3. *Passage of "loose body" from back to front of joint.*—The shadow of the "loose body" in the first radiogram showed that it lay in the posterior part of the joint, but at operation it lay in front of the anterior crucial ligament. As I have met with the same phenomenon before, and as I know of one joint surgeon who maintains he can bring a "loose body" from the back of the joint to the front at will, I am led to the conclusion that the simple manipulation of bending the knee in the manner described—the patient lying on the back and the foot being kept in contact with the table—is sufficient to press the "loose body" out of its position at the back and roll it forward to the front. This matter could be easily determined by radiograms taken before and after manipulation, but I have not since this case come across another suitable one. If this be so, in future it may not always be necessary to split the patella to get out the "loose body"; all that may be required will be to split the ligamentum patellæ and extract the "loose body" lying immediately beneath it.

Harley-street, W.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The opening meeting will be held on Friday, Oct. 4th, at 8.30 P.M., in the Society's Rooms, West London Hospital, when the new President, Lieutenant-Colonel E. M. Wilson, C.B., C.M.G., D.S.O., R.A.M.C., will be inducted and the presentation of the Keetley Memorial Medal will be made to the retiring president, Dr. A. J. Rice-Oxley. The Presidential Address will be on the subject of "Ancient Physic." Communications should be made to the honorary secretaries, Dr. H. H. Sanguinetti and Dr. J. F. Halls Dally, and subscriptions paid to the honorary treasurer, Dr. T. Gunton Alderton.

MENINGITIS CAUSED BY THE *MICROCOCCUS FLAVUS*.

BY JOHN H. TEACHER, M.A., M.D. GLASG.,
ST. MUNGO (NOTMAN) PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF GLASGOW AND PATHOLOGIST TO THE GLASGOW ROYAL INFIRMARY;
AND
A. M. KENNEDY, M.D. GLASG.,
LATE CAPTAIN, ROYAL ARMY MEDICAL CORPS.

OF the Gram-negative cocci inhabiting the naso-pharynx the meningococcus only has so far been recognised as capable of producing meningitis. The possibility of some other member of the group giving rise to meningitis cannot be denied, but hitherto no sufficient evidence has been forthcoming. In a case of cerebro-spinal fever recorded by McIntosh and Bullook[1] the meningococcus was isolated from the cerebro-spinal fluid at the first lumbar puncture, and a mixture of this organism with the *Micrococcus flavus* at the second lumbar puncture, but all subsequent punctures yielded pure cultures of the meningococcus alone. In the case now recorded the meningitis was caused by infection of the meninges by the *Micrococcus flavus* alone.

The patient, a miner, aged 50 years,[2] was admitted to hospital for head injuries caused by a fall of coal. On admission a large scalp wound was found in the upper occipital region and some bruising about the chin. The nose was broken and there was much blackening about both eyes. Two days after admission slight delirium occurred and persisted for three days. This was followed by loss of consciousness for one day, and death ensued the next morning.

At the necropsy some atheroma was found in the coronary arteries, and considerable anthracosis and hypostatic œdema in the lungs; the liver and kidneys showed cloudy swelling, and the spleen was congested and of the "septic type," otherwise the thoracic and abdominal organs were healthy. There was well-marked purulent meningitis at the base of the brain, passing backwards round the medulla and cerebellum and forwards over the roots of the optic nerves; it extended upwards over the convexity, but the exudate was much less abundant here than at the base. The lateral ventricles contained thin, purulent fluid and the fourth ventricle thick pus. There was a fracture of the cribriform plate of the ethmoid which extended across the right orbital plate. Pus was present, extradurally, on the upper surface of the cribriform plate, but no tear in the dura mater could be made out. The nasal bones were broken, but there was no other fracture and no gross injury to the brain.

Films made from the purulent meningeal exudate at the base of the brain showed polymorph pus cells, a few large mononuclears, and Gram-negative diplococci, intra- and extra-cellular, in considerable numbers. The films were indistinguishable from those obtained in an acute case of cerebro-spinal fever, and provisionally it was thought that the organism was the meningococcus. Cultures were made on serum agar, and after 24 hours' incubation a well-marked growth was obtained. The colonies were well defined, fairly clear and translucent, but with the very faintest tinge of yellow in the centre. Although a little larger than meningococcal colonies at this stage they are not unlike them, the tinge of colour in the centre resembling somewhat the granularity frequently seen in their centres. After incubation for 48 hours, however, the yellowish colour was distinct and the growth abundant and confluent. Later the growth became more profuse and paint-like. The fermentation reactions were tested on glucose, maltose, and saccharose, in litmus-tinted serum agar. Acid was produced on all three sugars, thus confirming the diagnosis of *Micrococcus flavus*. Distinct acid production was observed on the maltose within 24 hours, but the change on glucose was only slight in this time. In 48 hours, however, both showed the reaction well marked. On saccharose slight acid production was observed only after 48 hours, and further incubation was necessary before the reaction became distinct. The organism was easily emulsified in saline, and did not agglutinate with any of Gordon's type meningococcal sera.

The *Micrococcus flavus* is a common inhabitant of the naso-pharynx, and has hitherto been regarded as a more or less harmless saprophyte, but the present case demonstrates its pathogenicity under suitable conditions. Apparently the infection passed from the nose through the fracture in the cribriform plate to its upper surface and thence to the meninges, although no rupture of the dura mater was obvious.

CASES OF CEREBRO-SPINAL FEVER

DEFINITELY TRACEABLE TO INFECTION BY A PARTICULAR CARRIER.

BY J. A. GLOVER, M.D. CANTAB., D.P.H.,
CAPTAIN, R.A.M.C.; OFFICER IN CHARGE, LONDON DISTRICT C.-S.F. LABORATORY.

CAN any case of cerebro-spinal meningitis be definitely traced to one particular carrier? As this question has recently been answered in the negative by several authorities, such as Staff Surgeon G. P. Adshead, R.N.,[1] and apparently by German medical opinion, as summarised by Galambos,[2] some cases investigated in the London District Cerebro-spinal Fever Laboratory may be of interest as furnishing an affirmative reply to the same question.

The frequent changes of position and population in naval and military sleeping quarters tend to make investigation of purely military cases difficult and complicated, but when the infection of relatives by soldier carriers returning on leave is investigated we are on firmer ground.

The investigations have two main practical difficulties:—

First, conclusive evidence of infection being derived from the visiting soldier demands (*inter alia*) a correspondence in type between the meningococcus attacking the patient and that carried by the soldier. The patient being nearly always removed to a civil hospital his type of meningococcus is seldom determined, and so an important link in the chain of evidence is usually wanting.

A second difficulty is the length of time (usually at least 14 days) which elapses before the soldier is examined, and in this time many temporary carriers will clear up.

Record of Cases.

The following two cases are particularly interesting, as in them the first condition is fulfilled. The patient's type of meningococcus is known, and is the same as that carried by the soldier.

CASE 1.—This case was that of a soldier, a recruit, who was sent to a depôt where there had been a recent outbreak of cerebro-spinal fever, accompanied by high carrier rates (70 per cent. of both cases and carriers harbouring Type II. meningococcus). He was there for five weeks, and on May 4th (the carrier rate being at this date known to be over 20 per cent.) he went home on short week-end leave and slept two nights in the same room as his only child. On May 8th the boy developed the disease, was admitted to St. Bartholomew's Hospital, and died there; the meningococcus grown from his cerebro-spinal fluid was Type II. On May 12th the father was swabbed and was found to be a carrier of Type II.

CASE 2.—This case was that of a wounded soldier awaiting discharge and employed in the R.A.F. He did not sleep at home, but being within an easy distance went home every day for a period of a week. Four days after this his baby, aged 10 months, developed the disease, was admitted to St. Bartholomew's Hospital, and died there. The meningococcus in the child's fluid was grown and agglutinated by the bacteriologist to the hospital, and found to be Type I. The father was examined at this laboratory some days later and was found to be carrying Type I.

Unless we make the very unlikely assumption that in these cases the children infected their soldier parents these cases appear sufficiently conclusive.

Now to recite some cases in which, although the type of meningococcus infecting the patient was unknown, yet the other evidence is, in my opinion, sufficient.

CASE 3.—In this case the soldier returned on leave from France on Dec. 23rd, 1917. On Boxing Day he was married, and the next day he and his wife went to his father's farm for their honeymoon. On Dec. 30th his little brother, aged nine (who was not sleeping in the same room) fell ill. The soldier returned to London on the 31st, and the boy's illness proving to be cerebro-spinal fever, the soldier was examined at the laboratory on Jan. 4th, 1918. His swab furnished an almost pure culture of meningococcus (Type III.). He has since proved a carrier of persistent character.

One cannot help feeling that the bride had a providential escape.

CASE 4.—A nurse, nursing in a hospital in a large military centre where there had been a severe outbreak of cerebro-spinal fever and where the carrier-rate had been very high, went home on week-end leave, and slept in the same bed with a lady. This lady developed the disease four days later and died from it. Eight days after the contact the nurse was examined and found to be a carrier of Type II., the prevalent type of the garrison and of the hospital where she nursed.

It is just possible, of course, that the nurse was infected by the patient, but the converse is almost certain.

CASE 5, a soldier, was in hospital in London with a broken arm. He was allowed to go home to tea on three successive days, August 26th, 27th, and 28th, 1917. His child developed cerebro-spinal fever on Sept. 1st. The soldier was not examined until Sept. 26th, when he was found to be a carrier of Type I. meningococcus.

[1] Special Report, Series No. 17, Medical Research Committee, p. 90.
[2] Medical Supplement of the Foreign Press, Medical Research Committee, July 1st, 1918, p. 214.

CASE 6, a soldier, was working in a Labour Company in London and was sleeping at home every night in the same room with his 12-months'-old baby. The baby sickened of cerebro-spinal fever and died, and 12 days later the father was found on examination to yield an almost pure culture of meningococcus Type I. He was a chronic carrier, proved very resistant to treatment, and had also a chronic cough.

CASE 7, a soldier, came home on leave from France on March 1st. His only daughter, aged 12, sickened on March 5th, and was thought to have measles. On the 16th the case, which proved fatal, was notified as one of cerebro-spinal fever, and on the 18th the soldier was examined and found to be a carrier, of a somewhat chronic type, of Type II. meningococcus.

Remarks.

I have here excluded any case in which the evidence of contact or time appeared at all ambiguous.

During the 12 months ending June 30th, 1918, 33 soldiers have been examined in this laboratory in connexion with cases of cerebro-spinal fever occurring in relatives.

In 6 cases there was no evidence of recent contact with the patient before the onset, the soldier having been summoned in consequence of the dangerous illness of the relative. These 6 cases may therefore be dismissed from this inquiry.

In 9 out of the remaining 27 cases (or in 33 per cent.) the soldier proved a carrier.

Note.—The average military carrier-rate shown by 9000 "non-contact" examinations by me in the same period is 9·2 per cent., and that of 375 ordinary military "contact" examinations is 9 per cent.

In one other case the soldier was probably a carrier, but the agglutination result was not absolutely definite.

In 3 of the cases in which the soldier proved to be a carrier the other evidence was ambiguous—i.e., the soldier might have been infected by the patient. In one ambiguous case, for example, the soldier's wife who contracted the disease was the matron of a hospital where some convalescent C.-S.F. patients had been recently received. The soldier husband, who had been home on week-end leave just previous to the date of his wife's onset, was found to be a very chronic and abundant carrier (Type II.). He came from a depôt known to have a high carrier-rate. Who can decide whether he infected his wife or if he were infected by her, or if it were but a coincidence?

Considering the foregoing cases in conjunction with those of Flack,[3] in my opinion we may fairly answer the question in the affirmative.

Reviews and Notices of Books.

Religio Grammatici: The Religion of a Man of Letters. By GILBERT MURRAY, LL.D., D.Litt., F.B.A., Regius Professor of Greek in the University of Oxford. London: George Allen and Unwin, Ltd. 1918. Pp. 47. Price 1*s.* net.—"Religio Grammatici" is the title of a Presidential Address to the Classical Association, delivered on Jan. 8th, 1918, by Sir Gilbert Murray, and it is an earnest and reasoned defence of the study of the past. The mere Present, he says,

"enslaves us most, narrows the range of our thought, cramps our capacities and lowers our standards."

As to the Future,

"You cannot study the future. You can only make conjectures about it, and the conjectures will not be much good unless you have in some way studied other places and other ages."

In material things we are far ahead of our forefathers,

"One may say roughly that material things are superseded, but spiritual things not."

Again,

"To search the past is not to go into prison. It is to escape out of prison, because it compels us to compare the ways of our own age with other ways."

The higher and more massive workings of our literature, says Professor Murray, from as far back as the days of Alfred, come from Palestine, Greece, and Rome, the Christian and classical tradition. We might add, as a gloss on this remark, that it is surely more than a coincidence that the "Sortes," that well known form of invocation of an oracular response, superstitious and vain though it may be, has been addressed to the choicest literature of three nations alone—namely, Homer, Virgil, and the Bible. The classics do retain a strange influence over even those whose reading does not generally lie in their direction. We came across a humorous recognition of this fact the other day in a modern novel:—

"On the day when the interviewer was expected he remained all day in his study, and put away books about Mr. Jorrocks, and threw down on the table his school copy of Virgil. ..... He imagined himself saying: 'I always find myself returning to the classics; there's nothing like them really, you know.' For some reason or other the interviewer never came."

Some of us, however, read the classics without the stimulus of an interviewer and find them full of wholesome doctrine necessary for these times. There is much talk about "peace by negotiation"; this was tried long ago, and the answer of the Allies is, *mutatis mutandis*, the same as that of Diomede, Iliad VII., 400:—

"Let no man now accept Alexandros' substance, neither Helen's self; known is it even to him that hath no wit at all, how that the issues of death hang already over the Trojans."

Or go forward some thousand years and see what Horace said in words which should be brought to the attention of every "pacifist" of the kind that asks for the peace that is no peace:—

"Qui perfidis se credidit hostibus,
* * * * *
Hic unde vitam sumeret inscius
Pacem duello miscuit."

The struggle is once more between Carthage and Rome, between a Carthage who, according to the poet's view, would enslave the world and a Rome who would set the nations free. And, finally, where can we find the aim of the League of Nations better set forth than in the words of the Prophet Micah:—

"But in the last days it shall come to pass that ..... many nations shall come and say, Come and let us go up to the mountain of the Lord and to the house of the God of Jacob; and he will teach us his ways and we will walk in his paths. ..... And he shall judge among many people, and rebuke strong nations afar off ..... nation shall not lift up a sword against nation, neither shall they learn war any more. But they shall sit every man under his vine and under his fig tree, and none shall make them afraid."

These are the lessons of the past, and they are true to-day.

Thyrea and Other Sonnets. By JOHN FERGUSON. Second edition. London: Andrew Melrose, Ltd. Pp. 44. Price 1*s.* net.—In this little book Mr. John Ferguson shows himself to be a considerable master of a difficult art, for he writes sonnets with ease and distinction. And more than that, he is a thinker of fine things, who can use slang so appositely that while his colloquial vocabulary adds realism to the treatment it does not detract from the dignity of the theme. Sonnet No. V., entitled "On Tour," which appeared in THE LANCET, is a good example of this power, which W. E. Henley possessed in such a marked manner. In fact, Mr. Ferguson in his hospital sonnets has fairly earned comparison with Henley.

JOURNALS.

British Journal of Children's Diseases. Vol. XV. July–September. Edited by J. D. ROLLESTON, M.D.—Dr. E. Stolkind and Dr. A. Lorey, of Moscow, in their article on paratyphoid fever in children, adopt the classification proposed by Stolkind some years ago into the typhoid form, the gastro-intestinal form, the choleraic form, and the respiratory or influenzal form. Illustrative cases of each group are recorded, as well as two examples of local infection—viz., pyelitis due to the paratyphoid B bacillus. The etiology, morbid anatomy, symptomatology, diagnosis, and treatment are discussed, and a bibliography of 134 references is appended.—Mr. John Priestley and Dr. Barbara Richardson, school medical inspectors of the Staffordshire County Council, contribute a paper on Tuberculosis as seen in Public Elementary Schools, based on the study of cases seen from the beginning of medical inspection in 1908 to 1915. Out of a total of 42,471 children inspected, 283 cases of tuberculosis of all kinds were found; 87 of these presented pulmonary tuberculosis, the disease being usually of the quiescent or latent type. 184 showed evidence of glandular tuberculosis; the cervical glands were affected in all, and in 2 the axillary glands as well. Forty-nine showed tuberculosis of the bones or joints, which was chiefly in a quiescent state with deformity resulting from previous disease, and 13 had abdominal or cutaneous tuberculosis. The following conclusions are drawn from a comparison of the tuberculous with the average child:—

1. The weight to height ratio gives little or no help in the diagnosis of tuberculosis in children.
2. A previous attack of any of the common infectious illnesses of children does not, in general, seem to predispose to subsequent attacks of tuberculosis.

3. There is no evidence that more cases of tuberculosis arise among the badly-environed children in Staffordshire than among the better environed, but this may mean that the former are, after all, not very badly off.
4. The writers' figures give no support to the belief that enlarged tonsils and adenoids, as indicated by mouth breathing, *materially* favour the development of tuberculosis.
5. There is no evidence that caries of teeth to any appreciable extent leads to tuberculosis or favours its development.
6. There is evidence that cervical glands are enlarged in tuberculous children much more frequently than the average, not only in glandular tuberculosis, but also in pulmonary and other kinds.
7. There is no evidence that tuberculosis favours, or is favoured by, heart affections.
8. There is evidence that the tuberculous have fewer dull and backward among them than the average group, and, on the other hand, that they yield a larger proportion of mentally deficient cases.
9. There is evidence that the tuberculous group yields an unduly large proportion of cases of defective sight and eye diseases, but the difference is not marked. A similar and more marked difference is noticed in ear diseases.
10. Anæmia is very prevalent among the tuberculous, and nutrition is markedly depressed.

—In her paper on External Eye Diseases in Elementary School Children Dr. Barbara Richardson discusses (1) the incidence of these diseases according to age and sex; (2) the particular eye diseases found and their relative numbers; (3) the effect of the child's environment and its constitution on the incidence of the disease; (4) the clinical appearance of the various eye diseases as seen by the school doctor; (5) the relationship of defective vision to blepharitis; (6) the relationship of the common infectious diseases to external eye diseases; (7) the relationship of skin diseases to external eye diseases; (8) the relationship of enlarged tonsils and adenoids to external eye diseases.—Captain Alex. Mitchell, in a paper on Lacerated and Infected Joints in Children, records three cases illustrative of the modern method of dealing with such conditions. The main points are complete immobilisation, along with extension, careful excision of all infected tissue, removal of foreign bodies, and washing out all débris and clots with a weak antiseptic, or preferably with saline solution, which does not cause any irritation of the synovial membrane. This is followed by immediate closure of the synovial membrane, or when infection of the synovial cavity is evident by placing small drainage tubes down to the openings in the synovial membrane and fixing them, so that they do not project into the joint cavity. The rest of the wound is left unsutured or dressed with salt pack or Bipp, which should not be disturbed until the synovial wound has had time to heal. Immobilisation must be maintained until all fear of lighting up the infection by movement is past.—Dr. George Pernet records two cases of partial sclerema neonatorum. Although syphilis could be excluded, both cases were successfully treated with mercury, hydrarg. c. creta gr. i. t.d.s. being used in both cases, and ung. hydrarg. in one case locally as well.—Mr. Hunter Tod relates a case of multiple papillomata of the larynx removed by operation (suspension method) after tracheotomy in a boy aged 4 years. Five weeks later death took place from acute membranous tracheitis and bronchitis of streptococcal origin.—The abstracts from current literature in this issue of the journal are devoted to acute infectious diseases.

The Indian Journal of Medical Research. Vol. V., No. 4.—In this number there are two contributions on the subject of kala-azar, the first of which constitutes the fourth instalment of a series of researches on the etiology of this disease carried out jointly by Lieutenant-Colonel J. W. Cornwall and T. Kesava Menon, of the Pasteur Institute for Southern India, Coonoor. Their three previous papers have already been published in former numbers of the *Journal*. They had shown that the bed bug cannot regurgitate the contents of its stomach in the act of feeding, and that therefore it cannot transmit kala-azar, or oriental sore, by its bite. The present investigations deal with the possibility of the contents of the bed bug's rectum containing the infection of the disease. The results, however, have proved negative. Although pure subcultures of the flagellates of *L. donovani* can readily be obtained by inoculating N.N.N. tubes from the stomachs of infected bugs up to 10 days from the date of feed, no subcultures of the flagellates could be obtained from the rectal contents of the bugs from 3 to 33 days after an infected feed; nor could resistant forms be detected microscopically in the rectal contents of bugs infected by *L. donovani*. Kala-azar may perhaps be transmitted by the rupture of an infected bug on an excoriated skin, but so far no proof of this has been obtained.—The second paper is by Captain R. Knowles, of the Edward VII. Memorial Pasteur Institute, Shillong, and is entitled "Notes on Some Results in Kala-azar," in which the treatment of cases by intravenous injections of tartar emetic is discussed, and the conclusion reached that this is at the present time the best of all methods for treating this grave malady. Captain Knowles also deals with the possibility that some common intestinal parasites, such as ankylostomes, may be concerned in the hereditary transmission of the flagellates, or some developmental form of *L. donovani*. Further study of this subject is suggested.—Lieutenant-Colonel W. Glen Liston and Dr. M. B. Soparkar contribute a joint article on Bilharziosis Among Animals in India, in which the life cycle of *Schistosomum spindalis* is described.—Some observations on the Biochemistry of Post-choleraic Uræmia are supplied by Captain J. A. Shorten, to which is appended a note by Assistant Surgeon J. Makherji on the action of liquor calcis on comma vibrios, his conclusion being that as this fluid is distinctly inimical to the growth of these organisms it would help to check their growth in the intestines of the patient if liquor calcis were administered in large quantities.—Dr. Baini Prashad, D.Sc., assistant professor of zoology, Lahore, furnishes two papers on the Anopheles Mosquito, both being copiously illustrated by plates. In the first he describes in detail the constitution of the wings and thorax of the insect, and in the second he gives a description of the development of the dorsal series of thoracic imaginal buds of this mosquito, and supplies certain observations on the phylogeny of these insects.—The concluding paper of this number is contributed jointly by Dr. Karuna K. Chatterji and Dr. Charubrata Ray, of the Calcutta Medical College, and is entitled "Observations on Margosic Acid and its Salts, and their Use in Cases of Syphilis and Skin Diseases," with several coloured plates. Margosic acid is derived from the margosa tree, the Bengali *nim* or the Hindu *nimb*, the virtues of which have long been recognised in India for the prevention of fevers, leprosy, and other diseases.—As this number completes the fifth volume of the *Journal*, indices of authors and of subjects are appended.

The Military Surgeon.—In the issue for August it is shown that when the United States began to build up its great army it soon became obvious that very careful but rapid examinations must be made of all men soon after entry, in order that those infected with tubercle might be excluded, and excluded before they became chargeable to the public as having contracted the disease in the service. Special boards of examiners were accordingly set up, a standard scheme of examination devised by Colonel Bushnell was directed to be used, and the new soldiers were examined. After a million and a quarter had passed before the boards it was found that about 11,000 (0·783 per cent.) were infected and had to be discharged. If these men had been allowed to continue at their strenuous military training many would have broken down badly; from that risk they were saved, and any who did get through to France and had to be invalided from there must have cost the country, uselessly, £1000 apiece. So the advantage of the boards to the men themselves, to the Army, and to the public was very great. For their treatment the United States had already in the summer 1300 beds available and will have 6000 by Christmas. Of these beds 550 are to be used in a training school in which physicians are being specially trained as examiners for tuberculosis and to take posts in sanatoria. It is recognised that rest is the great need of the tuberculous patient, so he is sent at once to a sanatorium, and is given no leave until he is strong enough to withstand the fatigue of a visit to his home and friends, and in the sanatoria treatment is standardised so that patients may not be confused by varying directions given by different medical officers. A very interesting article on the organisation of one of these tuberculosis examining boards and on its work is given by Surgeon Lawrason Brown, U.S. Army, and Major J. H. Pratt, M.R.C. It is noted that, commencing daily at 8 A.M. and 1 P.M., it is easy for each member to examine 40 or 50 men in each session of two or three hours. This paper will well repay perusal.—Major Eric P. Quain and Captain Carl Eggers, M.R.C., U.S. Army, report having seen a considerable number of soldiers complaining of painful abdominal scars. Many of the complaints were exaggerated in the hope that the condition might excuse them from service. Yet none have been discharged; seven were operated on and have returned to duty. These seven could be arranged in four classes: (1) Adhesions of gut and omentum to parietal peritoneum beneath the scar; (2) submuscular herniæ of omentum through peritoneum incompletely closed; (3) thin scars (treated by excision); and (4) retained appendix following abscess drainage (treated by removal). This is a valuable paper.—There is also a most appreciative account of the orthopædic hospital for disabled soldiers at St. Helens in Lancashire.—As we read this number of the *Military Surgeon* it is constantly brought before us how great a work was the organising of the U.S. National Army, in how wise a scientific spirit it was undertaken, and what an advantage it was that they were not so overwhelmed as France and England with the suddenness of the war.

LONDON SCHOOL OF MEDICINE FOR WOMEN.—The inaugural address for the session 1918–19 will be delivered on Tuesday, Oct. 1st, at 3.30 P.M., by Miss A. Maude Royden (assistant preacher at the City Temple), who has taken as her subject "Revolutionary Thought."

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 28, 1918.

The Attributes of the Successful Flying Officer.

"IF men were meant to fly they would have been given wings." A few years ago such a remark was common enough, especially during the period when the pioneers of flying were making their fundamental experiments. Now, as a result of their successful efforts, man is able to fly, and flying is an everyday performance. It is true that man has not developed wings, but he has provided himself with a motor and wings. These are accessories to himself, but nevertheless, in flying he and his machine become, to all intents and purposes, a single entity. But that this entity is an artificial one is shown by the fact that, although flying has become possible, not all men can acquire the art of flying. To do this certain physiological attributes are especially necessary. In addition, if not perhaps even more important, is a psychological attribute—namely, the flying temperament; and to identify this temperament, and give it full play, is one of the difficult tasks before the executive, medical and other, of the Royal Air Force.

From a strictly physiological point of view it is obvious that, since man has added to himself wings and a motor, the most important factor in the art of flying is the nervous control and coördination of the reflexes necessary for the successful management of these accessory parts. An insight into these reflexes and their control is easily afforded by getting into a stationary machine and studying the fundamental effector movements ("effector responses") necessary to flying. The combination of hand and foot movement is by no means familiar to the average person, and while attention is directed to one movement, the other movement, equally important, is for the time being neglected. Thus when the attention is directed to the hand movement, the foot movement is forgotten for the time being, and becomes incoördinate. This is brought out even more effectively if, instead of being performed in a stationary stable machine, the movements are tried in an unstable apparatus which responds to each movement of the joystick and rudder. In these circumstances it is quickly realised that it is a matter of very great difficulty to maintain by appropriate arm and leg movements an even keel while in a state of unstable equilibrium. In practically no other acquired accomplishment has man to keep so many groups of antagonistic muscles in a state of "static" wakefulness, or to perform such a variety of constant coördinated leg and arm movements. It is for this reason that the acquiring of the art of flying, even in the apt pupil, is a matter of hours and not of minutes. For this reason also the period of training for flying is relatively long; time is necessary before the essential movements in flying can develop into more or less subconscious reflexes. It is certain that the man who has not the power of accurately coördinating his arm and leg movements will be deemed "ham-handed" or "heavy-footed," and will be held unable to acquire the art of flying. It is because of the importance of the delicately coördinated effector responses that great value is attached to a history of proficiency in sport in the selection of aviators. While a history of sport is of great importance, even greater is a history, if it can be ascertained, of acquiring a proficiency in sport easily. In other words, the likely man will have shown himself an adept at acquiring rapidly a new series of reflex acts.

On the sensory side of the flying reflex arcs it is necessary that the sense of vision be good and that the subject be possessed of a good "eye," wherefore great attention is paid in all the Allied countries to the determination of the time of the experimental visual reflex, especially in the selection of scout pilots. Again, the auditory sense is of considerable importance, especially in the detection of any mechanical defect in the running of the engine, and also because the airman obtains much information as to the position of his machine by the singing of the wind through the wires. Considerable divergence of opinion exists as to the part played by afferent impulses from the eye, kinæsthetic sensibility, and the vestibular mechanism. In regard to the last, it is frequently argued that since the vestibular mechanism is especially developed in birds, it is important that men in whom the mechanism is functioning especially well should be selected for aviation. True as this may appear at first sight, the fact must not be overlooked that, regarding the man and his machine as a single entity, the accessory parts added to man have, to a considerable extent, their own sense of balance. In other words, it must not be overlooked that most modern machines are possessed of an appreciable degree of inherent stability, and on this account there is no reason to suppose that machines cannot be effectively flown by men in whom the vestibular mechanism is not especially sensitive. This may well be the case, since it is known that cutaneous sensations, especially those derived from contact with the seat and from alteration in the direction of wind pressure against the cheeks, play with most pilots a really important part in giving them an idea of their projection in space. The visual reflex also normally has a great share in the sense of balance; an especially capable pilot found by experiment that he was quite unable to fly when blindfolded. Early in his flying career the aviator must be able to divert his attention from the arm and leg movements of flying. It becomes necessary for the pilot to find his way across country, to read maps, to practise photography, bomb-dropping, and gunnery, during all of which actions the machines should be flown more or less subconsciously. Finally, having acquired such flying sense, it becomes the lot of many pilots to perform subconsciously difficult aerobatics, while acquiring what may be known as the "fighting sense." It must again be emphasised

here that in the acquisition of these adjuncts to flying, quick visual response is needed. It is for this reason that during ground training of the flying officer, and also throughout his career, especial attention should be given to those sports which aid in the acquisition of what may be termed "eye." Of especial value in this connexion is fencing, but other sports—such as boxing, tennis, and badminton—are of great service.

Thus far we have been dealing with the acquisition of the art of flying. It is necessary also to consider the strain imposed on the body by the effects of altitude. The increased speed of the machines, their heightened ceiling, the greater rapidity with which they climb have carried aerial warfare to such an altitude that the aviator has to be able to perform relatively heavy work in an atmosphere where the oxygen tension is diminished. Thus, superadded to the nervous strain involved in learning to fly is the physical one which falls particularly upon the respiratory and circulatory mechanisms. To understand this strain it should be explained that these mechanisms are called upon to function in an atmosphere of diminished oxygen, where if anything an increased supply is required; there is thus the tendency to the establishment of a vicious circle, a demand for increased oxygen-supply in an atmosphere in which it is progressively diminishing as the aeroplane mounts. Many of the symptoms from which airmen are liable to suffer are due to the strain thrown upon the respiratory and circulatory systems. For this reason the would-be aviator must start out upon his training with a particularly sound constitution, above all with flawless circulatory and respiratory mechanisms. On this account great care must be exercised in his selection for the service, while herein lies a reason for the elaborate and careful organisation of a medical branch of the Royal Air Force. The conditions of service in this Force are published on another page of THE LANCET, and the way in which they have been devised to secure for aviators the best scientific assistance will be recognised at once. Obviously, the flying officer after admission should keep himself fit by sports which train these circulatory and respiratory mechanisms. Such sports are football, boxing, and cross country running. But given all the right physiological attributes, a man will never fly successfully unless he possesses the flying temperament, and so we come back to the points with which we started. Generally speaking, the really successful aviator is possessed of the temperament so characteristic of the pioneers of flying. He is endowed with absolute fearlessness, love of sport and adventure, and a dogged determination to overcome difficulties, no matter how insuperable they appear.

But, as Captain T. S. RIPPON and Lieutenant E. G. MANUEL point out elsewhere in our present issue, the airmen of to-day are not necessarily super-men. On intimate acquaintance it is found that practically all aviators possess one most precious asset—cheerfulness. Successful flying officers are, as a rule, most cheery souls. In trying to particularise in regard to the temperament of the successful flying officer, it must be borne in mind that there are various forms of aerial work which by no means require the same form of temperament. Thus a temperament suitable for the pilot of a scout machine is not necessarily suitable for the pilot of a low-flying reconnaissance machine or even of a two-seater bomber. For this reason, therefore, it is not prudent to do more than generalise as to the characteristic attributes necessary for success in flying. An idea of these attributes is excellently portrayed in the article by Captain RIPPON and Lieutenant MANUEL. There is sometimes a tendency in the popular estimation to allow the work of the fighting scout who has "downed" many enemy aviators to obscure the value of the less pretentious activities of the flying officers engaged in bombing, photographic reconnaissance, and artillery observation. The men engaged in these forms of aerial work are serving the cause every whit as successfully, although from the public point of view they do not enjoy so spectacular a career. The flying officer must be an enthusiast. To achieve success every flying officer must be keen. Without the flying temperament the pupil will never learn to fly successfully; without the fighting temperament he will never make an efficient war-time pilot. Given equal machines, the British pilots should in the end outdo their German rivals, since, by virtue of heredity, education, and training they have acquired those characteristics which make for successful flying. They possess in great measure the all-essential cheerfulness of spirit; their love of sport has given them soundness of wind and limb, cultivated the "eye," and endowed them with the power of rapidly acquiring new reflexes. Above all, they have learned to go in and win, even against odds, to "stick it" when in, and never to leave a "pal" in the lurch. With such a spirit prevailing, and an adequate supply of material, there need be no apprehension as to the British position in the air.

Medical Men for Parliament.

THE names of several medical men have been mentioned recently in connexion with various Parliamentary constituencies, some having decided to stand out of individual wish, and others responding to invitation from responsible bodies. Their action is the expression of a widely held feeling among medical men that as medical science is to play a large part in the social reconstruction of the nation in the near future it is high time to determine what that part is to be. Not only is it high time, but, supposing that a general election is imminent, the date has probably gone by when any medical man can hope to be adopted as a party candidate for a seat, and the point is not without significance. Those members of our profession who attempt to enter the House of Commons in any election that may be near at hand will have to depend upon their individualities and reputations for their chances, together with such public recognition as can be

obtained from the fact that in the immediate future medicine will form a common ground upon which all plans of rehabilitation of ordinary life, and all schemes for the betterment of social conditions, must depend. Party organisation will, as a rule, not assist medical candidates.

As we have already announced, a meeting will be held at the Steinway Hall, Wigmore-street, London, on Tuesday, Oct. 1st, at 5.30 P.M., under the chairmanship of Sir HENRY MORRIS, the object being to secure the election of representative medical men to the House of Commons, so that expert advice may be available on vital questions concerning national health. All members of the medical profession are invited to attend this meeting, which is designed to support the view that medical men are wanted in the legislature, not to speak for the medical profession, but to make clear to those who frame our laws the bearing that the various measures may have upon the prevention and the spread of disease, and especially upon the general physique of our population. The probability is that the meeting will be rather preliminary to future movement than influential at the present moment, but as it will be open to all members of the medical profession—and we hope that there will be a large attendance—the questions to be debated should be of the first importance in clearing the ground for subsequent action. Hitherto the opinions of the medical profession have not had the influence in public affairs that they should have. The medical voice when raised in protest has often been disregarded. Medical advice has been usually sought when the mischief has been done. Medical views have been quite regularly as well as quite untruthfully represented as being directed only to obtaining privileges and monopolies for the members of the medical profession. The reasons for this position are numerous, and before we blame the public for not understanding collective medical aims and aspirations, we have to think how far those aims and aspirations in a form representing unity of spirit and ideal ever find public voice or public expression. The medical profession is quite insufficiently represented in the House of Commons by men who are in actual touch with some of the most important questions of local government and national welfare; but before we can expect the public to signify by ballot that they wish to be represented by medical men, we must satisfy them as to our common policy, as a profession, upon the principal matters requiring social adjustment and reformation. The ideal medical man in Parliament must not represent medicine only. He should be an interpreter of medical thought and aims to his fellow legislators. The better housing of the poor and the improvements of the conditions of labour are two things which will occupy the attention of legislation immediately after cessation of the war, and probably the future progress of this country will be enormously influenced by the method in which the indicated problems are attacked by the popular representatives in the House of Commons. If medical men are to be accepted with warmth as candidates for the popular suffrage, it will not suffice for us merely to go on attributing much disease to bad domestic environment or to evil factory conditions: it will be necessary for us to show how a medical profession, which has a common aim and to which there has been given proper opportunities, can lead in the abolition of social abuses.

Recently we asked the question how far the medical practitioner of the future, whether as a candidate for the House of Commons, or as a canvasser or voter, will have to "mix himself up with politics." It is a question which the future must, to some extent, be left to decide; but the attitude of standing aloof from social questions, when or because they have acquired a political aspect, must be dropped by all the doctors of the future. The medical man's part will be to place his science at the disposal of the public, and justify that science by precept and example. As candidate for Parliamentary election and later as Member of the House of Commons the medical man will necessarily have to study party questions, but his views even here will require the endorsement of his professional colleagues if they are to be of weight. The medical man who enters Parliament will not be able to do so as a "Member for medicine"; he will have to appeal to constituents as a man of affairs who will serve their interests and that of his country with full qualifications to do so; but his value to those constituents will be enhanced by his medical training and knowledge. The ideal medical candidate for Parliament is not likely to be found in large numbers or in many constituencies. When he is found, however, he should secure the support of his medical colleagues where they can conscientiously give it, and this should bring him votes where the public hold the profession of medicine high. A medical practitioner, equipped by his calling and experience of life to exercise judgment in many subjects outside the range of his profession, broad-minded and independent, will be more likely to serve his country usefully in Parliament than the majority of those who compete with him for the honour of doing so. On general grounds he should be a good Member of Parliament, while his special attributes must be valuable in countless directions. We hope that the meeting at the Steinway Hall next Tuesday will lead to practical steps.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND: SUBSCRIPTIONS TO THE SECOND APPEAL.—The following subscriptions have been received up to Monday last, Sept. 23rd:—

	£	s.	d.		£	s.	d.
Dr. G. Vernon Bull ...	2	2	0	Dr. Alfred Cox (monthly)	1	1	0
Capt. J. S. Clarke, R.A.M.C.	3	3	0	Capt. E. L. Lilley, R.A.M.C. (T.)	2	2	0

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W. 1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

Annotations.

"Ne quid nimis."

THE WORK OF THE NATIONAL SERVICE BOARDS DURING 1918.

AN official statement emanating from the Ministry of National Service illustrates the practical value of the work which has been done by the National Service Medical Boards in Great Britain during the current year. In the course of the eight months of the year ending August 31st the number of medical examinations conducted by the boards in Great Britain amounted to over 2 millions, and during this period 28,000, or about 1·3 per cent. of the examinations, led to applications for medical re-examination. Of this number of applications less than half were considered by the appeal tribunals to rest on substantial grounds, while in the case of those applicants who obtained leave to be further examined by the medical assessors of the Local Government Board, the grading of half remained unchanged. The words of the Ministry of National Service that "converted into practical terms this result is expressed by the statement that National Service Boards working full time and examining 25 men per day of two and a half hours graded one man per week incorrectly" are fairly based on the figures, but the Ministry is of course perfectly aware that a very large number of appeals might have been made which for patriotic reasons were not advanced. This is a spirit of which the country has a right to be proud. Moreover, in many men the grading must to some extent be conditional; the great probability that a man may be able to discharge the responsibilities of his grading may not be justified in the event. The National Service Medical Boards have had many critics—some wise and some not, some honest and some not; but such figures form a challenge to criticism, however inspired, so long as those who challenge them understand their limitations as well as their origin. For our part, having all the circumstances in mind amidst which the National Service Medical Boards were created, we agree with the Ministry in considering that so fractional a percentage of error constitutes a record of which the medical profession has every right to be proud. And those responsible for the administrative machinery may similarly feel satisfied with their work, for it must be remembered that this machinery was created in a period of unprecedented strain upon the medical profession, in a country where the whole idea of conscription was novel, and where the difficulties were enhanced by the alteration in military age made by the Military Service (No. 2) Act. An important medical aspect of the work is the fact that the results of grading reveal a low state of national health, and it appears that the boards engaged upon the medical examination of women for State service have arrived at broadly similar results. The details of this immense mass of medical examinations have not, of course, been worked out, but we cannot hope that analysis will reveal anything but a most unsatisfactory story. Sufficient indications, and those of a pressing sort, have been obtained that the State must be ready to take effective measures on broad lines directly the war ends. The figures will undergo sifting and collating at the hands of the scientific advisers of the Ministry—indeed, this work has already been started.

CONCERNING MALARIA.

THE *Indian Medical Gazette* for July, 1918, is a "Special Quinine and Malarial Number," containing four original articles—two on treatment, two on prophylaxis. Those who have followed the researches on malaria conducted in this country during the war well know that so far it has not been found possible to *cure* simple tertian malaria infections by quinine used in any dose in any way, and that the fundamental fallacies underlying the pre-war text-book were traceable to a lack of adequate post-treatment observation period. Nor, so far, has salvarsan proved any more effective, though its "specific" action is just as well marked as that of quinine. How far these statements apply to malignant tertian malaria we cannot say, though the evidence is very clear that *Plasmodium falciparum* and *P. vivax* react differently to quinine and salvarsan, and it is consequently imperative that authors when they write of quinine and malaria should state to what exactly they are referring. There is, so far as we are aware, no evidence on record proving that a first attack of any form of malaria is more readily cured than a relapse. Of the efficiency of intramuscular injections of quinine, even in the strength 1 g. in 2 c.c. of water, in simple tertian malaria there is not the slightest doubt. Those who still conduct academic discussions on the point should read the literature. The fact, if it be so, that quinine (or what is supposed to be quinine) has been found *in situ* post mortem cannot stand against the clinical and microscopical evidence. Ramsden's and Lipkin's work suggests that it may not be quinine itself but a metabolite of quinine that is the actual parasiticidal agent; and, further, there is evidence that muscle possesses this power of metabolising quinine. The finding of "quinine" *in situ* in muscle may be, in fact, the very reason that intramuscular injections are so successful—viz., the muscle is exercising its metabolising function, a function which blood as compared with muscle possesses to hardly any appreciable extent. These are speculations, however, and do not in the least touch the established fact that intramuscular injection of quinine, even in 50 per cent. solution, is a good method of administering quinine in simple tertian malaria. Captain W. Fletcher, R.A.M.C., in a letter published in our present issue, expresses his belief "that 'quinine resistant' types of malaria are either extremely rare or non-existent." "A relapse," he says, "during adequate quinine treatment (defined above as 20 gr. or more every day) is, to say the least, uncommon"; but not only the records of such cases, in *simple tertian malaria*, but the frequency of their occurrence can be found in the literature for 1917. Major D. G. Marshall, I.M.S., has some instructive teaching on the matter on another page. In *simple tertian malaria* very little result is to be expected from such a quinine course. Quinine for the attack is a proved remedy, but no short road to *a cure* of *simple tertian malaria* by its means has hitherto been found. Quinine prophylaxis has not yet emerged from the ocean of contradictory statements that exist on the matter. There is only one method of putting an end to the confusion, and that is, to begin again, defining strictly the conditions of each experiment; it has not been generally recognised hitherto, for instance, that prophylaxis of a non-infected population and the "prophylaxis" (so-called) of an already infected population are two distinct questions.

The papers in the special number of the *Indian Medical Gazette* do not add much to our knowledge, and when quotations are given from older work, much of it is not satisfactory for various reasons.—"The Malaria Problem in Peace and War," by F. L. Hoffman, is a pamphlet of 100 pages, based on papers read at the annual meeting of the National Committee on Malaria, Memphis, Tenn., and at the Annual Convention of the New Jersey Mosquito Eradication Commission, Atlantic City, N.J. This able digest contains much matter difficult of access elsewhere, but while it gives a vivid idea of the vastness of the malaria problem, it can in no way replace the original papers, the study of which alone will reveal whether they are of value or not, a matter frequently impossible to ascertain from an abstract.

HELIOTHERAPY IN AFRICA.

HELIOTHERAPY has been principally practised on the continent, and only to a small extent in this country, partly because of less favourable climatic conditions and partly from want of appreciation of its value. In the *South African Medical Record* for July Dr. J. F. Haegert has reported remarkable results in South Africa, of which the following are some examples:—

An emaciated woman, aged 32 years, suffered from attacks of abdominal pain. The urine contained tubercle bacilli, which on catheterisation of the ureters were found to come from the right kidney. As an alternative to nephrectomy sun treatment was suggested. In two months she gained 15 lb. in weight and in a year was apparently cured.

A boy, aged 6 years, had been treated in hospital for tuberculosis of the hip by extension and fixation. He was pale and flabby and had a high evening temperature after any exertion. The head of the bone was eroded and there was shortening. After a few weeks of sun treatment he discarded his crutches and got about comfortably. After a few months he was robust and sturdy and apparently cured.

A Basuto, aged 40, had a rheumatic stiff hip-joint, with atrophy of the thigh muscles. After four months of sun baths, with massage, the hip-joint was quite free and the thigh muscles were normal.

A man, aged 52 years, had severe sciatica, with effusion into the knee-joint. The thigh muscles were flabby and atrophied. Sensation was practically absent in the three middle toes. He had been treated for 18 months by various practitioners in the large towns and operation on the nerve had been strongly suggested by one. He had tried different baths in the Orange Free State. The result was that he was bedridden and in constant pain. After a short period of sun treatment, with massage, he was a different man and could look after his farm work.

In early cases of tuberculosis cure was practically invariably obtained. In beginning sun treatment the first thing to do is to remove the coverings and confining apparatus and restore light to the atrophied limbs. By gradual stages the patient is trained to live in the open air and to tolerate prolonged exposure to the sun. Dr. Haegert recommends that the sun-bath be taken in a rectangular enclosure about 20 by 10 feet, the long axis pointing east and west, the sides made of reeds, mealie stalks, or zinc. The patient is clad in some white material and the head is protected with a white hat or an umbrella fixed to the bed. Dark glasses are worn to avoid the dazzling light. Irrespective of the locality of the disease, insolation is always begun on the lower limbs. Sunburn should never be produced. On the first day only the feet are exposed, next day the legs to the knees, then to the groins, then the abdomen, and finally the head and neck. As pigmentation advances precautions, at first essential, become superfluous, and daily insolations of four to six hours are given. Patients vary in the tolerance of the exposure. The rule is: Expose the patient as long as he bears it with pleasure and without lassitude.

SOCIAL INSURANCE IN GERMANY.

THOSE who have duties in connexion with National Insurance in the United Kingdom have been brought face to face with serious problems, increasing as the war is prolonged; but they may console themselves by considering how far more heavily the difficulties which weigh upon them are pressing upon those who in Germany are providing medical attendance, drugs, and necessary extra food for insured persons, out of limited and diminishing funds. In the New York *Spectator* for August 22nd the statistician of the Prudential Insurance Company of America calls attention to these difficulties as proved by the annual report of the Communal Sick Fund of the city of Leipzig, and criticises severely statements which he has met with, to the effect that Germany, by adroit falsification of Census returns in the past, deceived the rest of the world as to her man-power, and has since been able to maintain her resources by restoring an impossible proportion of sick and wounded soldiers to the battle-line. From the report of the Leipzig Communal Fund a diminution may be gathered amounting to more than one-half of the number of male members in the compulsory insurance section, and an increase from 31 to 56 per cent. in the proportion of women members of the same class. The report, however, gives no information as to the age of the women liability for whose health is imposed for the first time upon the fund, nor as to what proportion of them are married. The administration of the fund has evidently been lax, to the extent that it has not confined benefits to those provided for by its contract with insured persons, but has gone outside such limitations, charitably perhaps, or in obedience to instructions imposed by the State, but to an extent likely to have serious financial consequences. The results of dear and scarce food are to be clearly seen in the accounts of the Leipzig Fund, and are perhaps most strikingly illustrated by the increase in the number of malingerers. A large number of persons claimed medical benefits at Leipzig in 1917 in the hope of being able to supplement their food-supply under the doctor's orders, but failed to establish the fact that they were suffering from ill-health. In Munich a proposal that increased contributions to the Communal Fund should be demanded to meet an obvious shortage was defeated, and a resolution was carried by the employed persons interested that the deficit should be supplied from the reserve funds, a policy which must lead to insolvency if persisted in. The difficulties experienced in administering the National Insurance Acts in this country are growing, but they are still slight when compared with those experienced by our enemies.

"THE JOURNAL OF GENERAL PHYSIOLOGY."

THE opening number of a new periodical of great scientific interest in its outlook, entitled *The Journal of General Physiology*, is announced for issue this week in New York. The journal is intended to serve as an organ of publication for papers devoted to the investigation of life processes from a physico-chemical view-point. The preliminary statement points out what we have often suggested in these columns—that under the pressure of the demands of medicine and of other professions, physiology has developed in the direction of an applied science, with limited opportunity for the investigation of purely theoretical problems. On the other hand, the physico-chemical methods

of analysing life phenomena have thus far made little inroad into the domain of zoology and botany. In these circumstances the establishment of *The Journal of General Physiology* has been made with a very definite programme before the editors, namely Dr. Jacques Loeb, the Rockefeller Institute for Medical Research, 66th-street, New York City, and Professor W. J. V. Osterhout, Harvard University, Cambridge, Massachusetts. Contributions are invited relating to the physico-chemical explanation of life phenomena, no matter in what field of science they originate, and should be addressed to the editors at the Rockefeller Institute or 60, Buckingham-street, Cambridge, Mass. The subscription price is $5.00 per volume, is payable in advance, and issue is bi-monthly at the Rockefeller Institute, and should be paid by draft or cheque on New York or by postal money order.

THE VALUE OF TESTIMONIALS.

THE case of Nurse Eva Grace Thompson, tried before Mr. Justice Darling at the Central Criminal Court for the murder of a child aged 2 months at an "infant welfare centre," would have attracted more notice if the war were not absorbing the attention of all, for a second child's death and serious injury suffered by a third were probably due to the nurse's acts. Possibly, however, in time of peace no such tragic incidents as these would have occurred, for greater competition for the post held by Thompson would have caused a stricter inquiry into the character and antecedents of the candidate for it. As it is, this unhappy young woman was found guilty, but was also proved to have been insane when she fractured her little victim's skull. Evidence was given that she had spent three years in a home (1909 to 1912) as the result of addiction to drugs, and that she had recently fractured her own skull probably by striking it against the floor. She herself admitted that she had been under treatment for drugs, and Mr. F. J. W. Sass, deputy medical officer at Holloway Prison, gave evidence entirely consistent with these statements based upon his observation of the prisoner. In these circumstances it is evident that any close inquiry into the previous history of Thompson, described as a trained nurse, 33 years of age, would have prevented her engagement at an infant welfare centre or at any kindred institution. In her case, however, a written "reference" from a lady who "had known her personally and her work" had been accepted without further question. The difficulty of obtaining suitable persons in war-time for almost any post may account for, but cannot justify, the readiness with which such a vague testimonial was accepted. Many persons may now be obliged to employ for their private convenience men and women whom they would not consider for a moment if they had others to select from, but it is different where an institution is charged with the care of children or of other helpless persons. Moreover, at such institutions there is, or should be, no difficulty in obtaining the assistance of a medical practitioner in the selection of a trained nurse where the evidence to character and attainments is unduly slight.

KING'S COLLEGE MEDICAL SCHOOL.—The opening of the winter session will take place at the school, Denmark-hill, on Tuesday, Oct. 1st, when Sir Watson Cheyne will deliver the introductory address, after a short statement as to the position of the institution has been made by Dr. H. Willoughby Lyle, the dean of the school.

ROYAL AIR FORCE MEDICAL SERVICE.

THE conditions of the Medical Service of the Royal Air Force have now been made public, and will be received by our readers with considerable gratification. In obvious directions—for example, in the allocation of officers to suitable posts and in the opportunities given for promotion by merit—the conditions mark a real advance. The task of selecting flying officers, to mention one grand duty of the Medical Service of the Royal Air Force, presents many difficulties, which are discussed elsewhere in these columns; and from this point of view alone the recognition of scientific counsels by the Royal Air Force is very welcome.

CONDITIONS OF SERVICE.

General.

1. For the present two main, or special, divisions of the medical work of the Royal Air Force will be recognised—namely, (*a*) care of the effective personnel, and (*b*) care of the non-effective personnel.

2. The former may be considered to represent the hygiene and preventive side of the work, and to include such special subjects as selection and care of the flying personnel, maintenance and improvement of the physical efficiency of all ranks, sanitation, &c. The latter represents the curative side of the work, and certain subdivisions that Air Force experience has shown to be necessary will be recognised—namely, neurology, surgery of the eye, throat, nose, and ear, and plastic surgery, &c., in addition to general medicine, surgery, and pathology, &c.

3. Subject to the exigencies of the Service, a medical officer will be selected for, and eventually allocated to, work in the subdivision for which his ability best suits him. Since, however, the success of any special work in the Air Force will depend upon a sound knowledge of the conditions of life of the effective personnel, medical officers will not be earmarked for one of the special subdivisions of the Medical Service until selected for the higher or Grade A pay, vide Appendix II.

4. While it would be impossible for the Air Council to give any guarantee that an officer will be employed continuously on a line of work in which he happens to have acquired special knowledge, the endeavour of the administration will be in this direction.

5. It should also be generally realised by medical officers that the direction, or administration, of the divisions and subdivisions will be entrusted to those whose special knowledge of the subject, or subjects, will ensure the best technical control.

6. It will be observed (para. 21 and Appendix II.) that the system of charge pay as in vogue in the Navy and Army Medical Services has been replaced in the Air Force Medical Service by a system of special merit pay. An officer once selected for Grade A pay will draw such pay for a probationary period of one year, and if then confirmed, will, except in the case of incompetence or misconduct, continue to draw this pay however employed until promoted to the next higher rank, when he will be placed in Grade B until again selected for Grade A.

7. An officer appointed in charge of a hospital or other unit which in the Navy or Army would carry charge pay, or which previously was held by an officer drawing Grade A pay, is not thereby entitled to Grade A pay; nor will seniority of itself entitle an officer to Grade A pay.

8. A limited number of commissions as administrative officers (medical) will be available, and warrant officers and non-commissioned officers transferring from the R.A.M.C. or entering the R.A.F.M.S. direct will be eligible for promotion to these appointments.

9. Particular attention is drawn to the difference between the terms "transferred" (as applied to temporary officers) and "attached." The former implies relinquishment of any temporary commission held at the time of transfer; the latter is analogous to seconded service, and enables the officer in question to return to his original service at the end of a stated period without loss of seniority or pension in respect of such attachment.

10. Permanent commissions will not be granted at present, and the conditions of service and scales of pay set out in this Memorandum will be subject to revision at the end of the war, or before that time if the Air Council so decide. When a permanent Air Force Medical Service is established previous experience as medical officer in the R.A.F. will be taken into account in granting such permanent commissions.

Duration of Service.

11. No person will by reason of attachment or transfer to the R.A.F. become liable for service with the Forces for a longer period than that for which he would have been liable had such attachment or transfer not taken place.

12. Subject to para. 11, permanent officers of the Royal Navy, including officers who have joined the Reserve of Medical Officers from the permanent list, and Royal Naval Volunteer Reserve Medical Officers, will be *attached* to the R.A.F. for a period of three years or the duration of the War, whichever is the longer. Regular and Territorial officers or members of the Special Reserve of the R.A.M.C. will be *attached* to the Royal Air Force for the duration of the War. (Officers who are seconded from the Navy and Army will receive assurance in writing that their prospects of promotion by selection in their own service will not be prejudiced. Ref. 7070/18.)

13. Subject to para. 11, temporary medical officers of the Royal Navy or Royal Army Medical Corps and dental surgeons will be *transferred* to the Royal Air Force for the remainder of the period for which they were liable to serve with the Royal Navy or R.A.M.C., as the case may be.

14. Subject to para. 11, R.A.M.C. orderlies will be transferred to the R.A.F. for the remainder of the period for which they were liable to serve with the R.A.M.C.

Rank.

15. Promotion to ranks above that of Captain in the R.A.F. Medical Service will be by selection to fill vacancies in the establishment.

16. On attachment or transfer to the R.A.F. officers will receive temporary commissions in the R.A.F., with rank corresponding to their rank, substantive or temporary, prior to attachment or transfer as shown in Appendix I.

17. An officer attached to the R.A.F. receiving promotion in the Navy or Army during such attachment will receive corresponding rank in the R.A.F., and be held supernumerary to the establishment until a vacancy occurs in such higher rank in the R.A F. for which he may be selected.

18. Officers lent to the R.A.F. becoming attached or transferred to the R.A.F. will receive seniority in the R.A.F. from the 1st April, 1918, and will be placed upon the R.A.F. list in order, based on their seniority in the service from which they are attached or transferred.

19. R.A.M.C. orderlies transferring to the R.A.F. will be graded in ranks corresponding to their rank in the R.A.M.C.

Pay, Allowances and Gratuity.

20. Officers attached to the R.A.F. will be paid at the rates set out in Appendix II. (Grade B) subject to reserved rights as in para. 29.

21. A proportion of officers will be selected for pay at the higher rate (Grade A) on the recommendation of the Medical Administrative Committee. The Committee will take into consideration: (*a*) Length of service; (*b*) war or specially meritorious service with the R.N.A.S. or R.F.C.; (*c*) medical qualifications; and (*d*) any other special service or qualification possessed by the officer in question. The names of all officers transferred or attached will be periodically considered for selection to Grade A.

22. Medical officers attached to the R.A.F. will receive allowances on the scales laid down for corresponding ranks in the R.A.M.C. These allowances may be varied from time to time to meet the conditions prevailing in the R.A.F., but are at present similar to those issued to Army officers.

23. Temporary medical officers, both R.N.A.S. and R.A.M.C., transferred to the R.A.F., if not above the rank of Captain, will be paid at rates similar to the rates paid to temporary medical officers of the R.A.M.C.—namely, 24*s.* a day inclusive of all allowances except (*a*) ration allowance when rations are not issued in kind, and (*b*) travelling allowances and expenses when travelling on duty.

24. Temporary medical officers with the rank of Major (or senior to Major) transferred to the R.A.F. will receive pay at the rates for medical officers as shown in Appendix II., Grade B or A, as the case may be. This also applies to promotions after transfer.

25. Dental surgeons transferred to the R.A.F. will receive pay at rates similar to the rates paid to dental surgeons in the Army inclusive of all allowances except travelling allowances and lodging, fuel and light allowances when quarters are not found and they are required to live away from their usual place of residence in civilian life.

26. Temporary medical officers of the R.A.M.C. transferred to the R.A.F. will receive such proportion of their annual gratuity of £60 as has accrued up to the date of transfer and will hereafter receive a gratuity at the rate of £60 for each year's service in the R.A.F. This gratuity is awarded under the terms of the contract set out in Appendix III.

27. R.A.M.C. orderlies transferred to the R.A.F. will receive pay at the rates they were receiving in the R.A.M.C. as corps pay and basic pay. A special rate of pay for R.A.F. medical orderlies is under consideration.

28. Temporary medical officers of the Royal Navy transferred to the R.A.F. will receive a gratuity of £60 for each year's satisfactory service (vide Appendix III.) with the R.A.F., subject to a minimum of two months' pay at R.N. rates.

29. While it is impossible to pledge the future as to the prospect of individuals, and while reasonable latitude must be allowed to the Air Council to deal with any privilege or emoluments which are not subject to vested rights, it may be taken as a general principle that no person will suffer loss of emolument or pension by reason of attachment or transfer to the R.A.F.

30. In pursuance of this principle any person becoming attached or transferred to the R.A.F. will continue at the rate of pay he was already receiving where such rate was higher than the rates set out in this Memorandum.

31. An outfit allowance of £25 will be granted to officers becoming attached or transferred from the Royal Navy, and £10 in the case of officers becoming attached or transferred from the Army. Officers becoming attached or transferred from the Royal Navy with the rank of field officer in the R.A.F. will receive an outfit allowance of £30.

32. Officers having already received an allowance for khaki uniform in the Royal Navy will receive only £10.

APPENDIX I.

Rank in R.N.	Rank in R.A.M.C.	Rank in R.A.F.
—	Lieutenant.	Lieutenant.
Surgeon.	Captain.	Captain.
Staff Surgeon.	Major.	Major.
Fleet Surgeon.	Lieut.-Colonel.	Lieut.-Colonel.

APPENDIX II.

Daily Pay for Medical Officers (Excluding Temporary Medical Officers Under the Rank of Major).

Rank.	Grade B.	Grade A.
Lieutenant	14*s.*	—
Captain...	16*s.* and 19*s.*	22*s.*
Major	24*s.*	27*s.*
Lieut.-Colonel ...	35*s.*	40*s.*

APPENDIX III.

A.M. Form 161.

FOR GENTLEMEN SUBJECT TO THE MILITARY SERVICE ACTS.

To His Majesty's Principal Secretary of State for the Royal Air Force.

I.....

of.....

being qualified to practise medicine and surgery, and being registered under the Medical Act now in force in the United Kingdom, hereby offer and agree if accepted by you to serve at home or abroad as a Surgeon to His Majesty's Forces with the temporary rank of Lieutenant in the Royal Air Force while so employed, on the following conditions:—

1. The period of my service hereunder shall commence as from the day on which I shall commence duty, and shall continue until the termination of the present emergency, or until my services are no longer required, whichever shall first happen.

2. My pay shall (subject as hereinafter appears) be 24*s.* a day for the said period, such rate to be inclusive of all money allowances, except the regulated travelling allowances and expenses when travelling on duty.

3. In addition to such pay, I shall receive a free passage to any country abroad to which I may be sent, and (subject as hereinafter appears) a similar free passage back to England.

4. I shall receive free rations, or an allowance in lieu thereof, and when considered necessary for the performance of my duties the use of a Government horse and forage.

5. During the said period I will devote my whole time and professional skill to my service hereunder, and will obey all orders given to me by superior Air Force, Naval, or Military officers.

6. In case I shall have completed my service hereunder to your satisfaction in all respects, I shall receive at the end of the said period a gratuity of £60 sterling for each 12 months or part thereof, but in case I shall in any manner misconduct myself, or shall be (otherwise than through illness or unavoidable accident) unfit in any respect for service hereunder, of which misconduct or unfitness you or your authorised representative shall be sole judge, you shall be at liberty from and immediately after such misconduct or unfitness to discharge me from further service hereunder, and thereupon all pay and allowances hereunder shall cease, and I shall not be entitled to any free passage home or gratuity.

Dated this.....day of.....19.....

.....(here sign).

Witness to the signature of the said

.....

..... (Witness).

On behalf of the Secretary of State I accept the foregoing offer.

.....

Medical Administrator, Royal Air Force.

SOCIETY FOR THE STUDY OF INEBRIETY.—The next meeting of this society will be held on Tuesday, Oct. 8th, at 4 P.M., in the Rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W. 1, when Major Robert B. Wild, M.D., professor of materia medica and therapeutics in the Victoria University of Manchester, will open a discussion on "The Pharmacology of Alcohol." All interested in the subject are invited to be present.

Correspondence.

"Audi alteram partem."

QUININE RESISTANT MALARIA.

To the Editor of THE LANCET.

SIR,—Nowadays one hears frequently of malaria which is resistant to quinine, in the sense that while the patient is taking 20 gr. or more every day the fever endures beyond the fourth day; and though he continues to take quinine in undiminished doses, from time to time he has relapses associated with the presence of asexual parasites in the peripheral blood.

In this sense I believe that "quinine resistant" types of malaria are either extremely rare or non-existent. I am not concerned here with relapses which occur *after* the patient has reduced his daily dose of quinine below 20 gr., or has stopped taking it altogether; all of us are but too familiar with such cases, and I remember an *obiter dictum* of Sir Patrick Manson:

"We don't cure protozoal infections with drugs. We keep them in check until the resisting power of the patient can overcome them."

There are relapses in malaria after treatment with quinine; but a relapse *during* adequate quinine treatment is, to say the least, uncommon.

Now that many medical men without experience of tropical diseases are called upon to treat cases of malaria, it is of the utmost importance that they should know what a trusty weapon lies ready to hand and that their faith in quinine should not be undermined at the outset. Sir Patrick Manson writes:—

"Many drugs have been employed in the treatment of malarial disease, and many drugs have some influence on it; all sink into insignificance in comparison with quinine. To use any drug to the exclusion of quinine is serious trifling."[1]

In THE LANCET of June 22nd is an article by Major E. B. Gunson, Captain F. W. Winning, and Lieutenants G. A. Johnstone, J. H. Porter, and G. B. Scott, entitled "The Treatment of Severe Relapsing Cases of Malaria." The "routine treatment by oral quinine" consisted in putting the patient to bed and giving him at least 20 gr. every day until he was discharged from hospital. In this way 328 men were treated, with the result that 30 per cent. relapsed while they were taking quinine, and some of them developed long periods of sustained pyrexia or became increasingly cachectic.

These results are quite contrary to my own experience, and to that of many other workers. Captain David Thompson has reported[2] on the results of treatment by quinine of 200 patients who had contracted malaria in many different parts of the world. Only one of these 200 patients showed "quinine resistance," and in this instance the nurse "admitted that some doses had been omitted about the time of the relapse."

During the years 1904 to 1908 I was in charge of the General Hospital, Kuala Lumpur, Federated Malay States. This was in the early days of rubber planting; virgin jungle was felled, great tracts of country were brought under cultivation, new roads and railways were being constructed, and large gangs of imported coolies were gathered together for the work. In a tropical country such conditions almost invariably give rise to malaria in epidemic form, and the Malay States proved no exception.

Large numbers of patients were admitted to the hospitals, and the General Hospital at Kuala Lumpur had its share. I have no access to the figures at present, but the number of cases of malaria treated in that hospital during those years was well over 2000, about one-sixth of which were simple tertian infections and the remainder subtertian and quartan. These patients were under my personal care, and I saw them at least three times a week. In not more than half a dozen cases did a relapse occur while the patient was taking 20 gr. of quinine sulphate daily, and in each of the half dozen cases I had grounds for suspecting that the quinine had not been taken regularly. I have never seen a patient relapse a second time while he was taking 20 gr. of quinine every day.

My experience with soldiers who have contracted malaria during the present war has not been different from that gained in the tropics. From February to July, 1918, malarial parasites were found in the blood of 301 patients examined in this laboratory (*P. vivax*, 278; *P. falciparum*, 22; *P. malariæ*, 1). Each patient was given 10 gr. of quinine twice a day while he remained in hospital, with the result that in the great majority of cases the temperature came down to normal in a day or two. In 11 cases the fever lasted until the third day and in one until the fourth day after the commencement of treatment. Only two men relapsed, and I suspect that they had managed to escape some doses of quinine, for after special attention was paid to them the fever and the parasites quickly disappeared. This series is not strictly comparable with Major Gunson's; his patients stayed in hospital for seven weeks, but only 73 of these remained for more than a fortnight.

There is no cogent evidence that the malaria parasites in one part of the world are more resistant to quinine than those found elsewhere. *P. vivax* is as readily influenced by quinine whether it come from the Near or from the Far East or from any other part of the world. We have, most of us, heard of "quinine-fast" malaria parasites, but how many have actually encountered them? Has anyone ever seen a case of malaria in which the fever continued and asexual parasites were still to be found in the peripheral blood after the patient had been taking quinine in doses amounting to 20 or 30 gr. a day for four days and was continuing to take it?

The commonest cause of "resistance" is insufficient concentration of quinine in the patient's blood, due to insufficient dosage or to failure to take the drug regularly. Quinine is unpleasantly bitter and the soldier is not alone in trying to get out of taking it. Most people find it a dull business to look after cases of malaria who are up and about, so that it is not always difficult for the patient to escape his dose. If the administration be left to the patient one can be certain that quinine is not taken regularly. When I have been recovering from malaria myself I have found it impossible to remember my quinine; the only way in which I could insure taking it regularly was by making my "boy" put two capsules beside my plate at breakfast and again at dinner.

With reference to the form in which quinine should be administered a good deal has been written lately about the advantages of quinine injections in the routine treatment of malaria, but Sir Patrick Manson holds the opinion that "the intramuscular injection of quinine must not be practised without good reason or as the routine treatment of ordinary malarial attacks."[3] In 1905 I treated several hundred patients with injections of quinine, but I did not find that the results were any better than when it was given by the mouth, and I came to the conclusion that intramuscular and intravenous injections should be reserved for patients with very urgent symptoms, persistent vomiting or coma. It is very rarely necessary to continue to administer the drug by these routes for more than one or two days. Sir Ronald Ross writes: "I really do not know why this form of medication is continued in malaria."[4]

I do not wish to enter upon the question of malaria-prophylaxis and the prevention of relapses after treatment, but I will say at once that I have seen the best results from the routine administration, by the mouth, of 10 gr. of quinine twice a day, continued for as long as three months if possible, and then stopped entirely. I have found it a good rule to add 2 gr. to the 20 gr. for each stone above a weight of 10 st.

It is quite common to meet people who say that they cannot take quinine, but in reality an idiosyncrasy with respect to it (as manifested by urticaria with vomiting and collapse) is a great rarity. I have never seen anyone harmed by 20 gr. of quinine a day, even when continued over a long period. If the patient objects to the drug in liquid form the powder can be put up in the gelatine capsules which are supplied, empty, by Messrs. Parke, Davis, and Co.

In spite of general opinion, I think that quinine should be commenced as soon as malaria parasites have been found. To wait until the temperature comes down is wasting time; in some cases the temperature never comes down until the patient dies. Ten grains of aspirin give the greatest relief when there is fever.

HYPNOSIS IN HYSTERIA.

To the Editor of THE LANCET.

SIR,—I am glad to take the opportunity afforded me by Captain J. R. O'Brien's courteous letter in your issue of Sept. 21st to enlarge somewhat upon the question of the relation between hypnosis and hysteria, although a really adequate discussion of this relation would fill volumes. It is well known that Charcot failed therapeutically through his excessive enthusiasm for hypnosis. His methods were so vigorous, and he applied them so frequently upon the same subjects, that these subjects became more and more dissociated, more and more suggestible, more and more hysterical. Hence the *grande hystérie*, the *attitudes passionnelles*, &c., which are now so seldom met with. In other words, he "cultivated" hysteria at the Salpêtrière. But in doing so he made great additions to our theoretical knowledge of both hypnosis and hysteria. His failure as a physician and his success as a scientist are both summed up in his statement, "Hypnotism is an artificial hysteria." I consider this statement, as far as it goes, to be absolutely true. The more one sees of hysteria and the more one sees of the results of hypnotism the more convinced one becomes of the intimate relation between the two. That is why hypnotism is such a dangerous method to use in the hands of operators whose enthusiasm outruns their psychological knowledge and skill. Safeguards are necessary, and in my article in THE LANCET of August 17th I have indicated the modifications of ordinary hypnotic procedure which I have found practically satisfactory in dealing with hysterical soldiers in the field shortly after their exposure to shell fire. Shell concussion, or the mental strain of being under shell fire, had already hypnotised them and produced a certain amount of mental dissociation in the form of amnesia, loss of motor or sensory functions, &c., without demonstrable organic nerve lesions, and by means of my method of light hypnosis I was able to remove the underlying cause of this dissociation and neutralise it by subsequent re-association.

No doubt there are other forms of dissociation besides that of hysteria. But the point is that the dissociation of hysteria and the dissociation of hypnosis are identical in nature. Captain O'Brien writes: "Thousands of healthy men absolutely devoid of any trace of hysteria have been hypnotised, while hysteria itself, instead of favouring the induction of hypnosis renders it more difficult." With the second half of this statement I entirely disagree. My experience has been that the more hysterical a patient is the easier it is to hypnotise him. I also believe that when an apparently normal person is hypnotised he is rendered temporarily hysterical by the very process of hypnosis, the vigorous emotional appeal of the operator producing a dissociation of a hysterical nature. Such a person will be more hysterical thereafter, and will be more susceptible to hypnotism, unless steps are taken to counteract this effect. I, of course, recognise how large a proportion of apparently normal people can be hypnotised by one means or another—although in many cases the degree of hypnosis is slight—but then most people, if not all, have some hysterical flaw, some dissociation following upon mental conflict, in their mental make-up. "Jedermann ist ein bisschen hysterisch," said Moebius, and this slight degree of hysteria is what ensures the success of the resolute hypnotist. The mild methods which I myself use have no effect upon apparently normal persons, although they are invariably successful with hysterical soldiers hot from the firing line. In my opinion, more impressive methods are to be deprecated, as their dissociative effects are difficult to neutralise afterwards.

When Captain O'Brien writes as follows: "Pierre Janet's theory that only hysterical patients can be hypnotised rests on the assumption that the presence of the secondary self is always a symptom of hysteria," I am again unable to follow him. Pierre Janet has no dealings with a "secondary self." He prefers to avoid hypothesis as far as possible, and to speak simply of dissociated ideas. When these ideas are sufficiently numerous and linked up with one another, they may produce the appearance of an alternating or dual personality. The essential psychological characteristic of the hysteric is, in Janet's view, a weakness of mental synthesis. I can only repeat that my personal experience with cases in France agrees closely with the views of Janet, but is at variance with much that has been written elsewhere. It seems to me that only by the aid of hypnosis and other forms of mental analysis will the problem of hysteria be finally solved. I am, Sir, yours faithfully,

WILLIAM BROWN,
Major, R.A.M.C.
Craiglockhart War Hospital, Edinburgh, Sept. 21st, 1918.

DRIED *V.* CONDENSED MILK: A CORRECTION.

To the Editor of THE LANCET.

CHER MONSIEUR,—Je me permets de recourir à votre haute impartialité pour vous demander de bien vouloir rectifier dans le prochain numéro du "LANCET" l'erreur de traduction qui s'est glissée à l'occasion de ma précédente lettre sur le lait condensé.[1] Cela vous apparaitra d'autant plus nécessaire que cette erreur dénature complètement ma pensée et le sens de ma lettre. En effet, je disais:

"Mes dernières recherches me permettent de conclure que les laits condensés non sucrés sont inférieurs aux laits condensés sucrés et j'affirme que les laits *écrémés* constituent des produits dangereux pour les jeunes enfants."

Or votre traducteur a écrit:

"Unsweetened condensed milk he considers positively dangerous."

Il y a là une interprétation qui me fait dire le contraire de ce que je pense: Ce sont les laits condensés privés de leur crème qui je considère comme dangereux pour les enfants, mais si j'estime aussi que le lait condensé sucré est le meilleur aliment de la 1ere enfance je reconnais après une longue expérience et je l'ai declaré dans de nombreuses publications, que les laits condensés non sucrés (mais contenant leur crème), sont néanmoins excellents et bien préférables à tous les autres laits en usage dans l'alimentation de la 1ere enfance.

Votre souci de la vérité scientifique, m'assure que vous voudrez bien, cher Monsieur, corriger la fausse impression qu'ont pu avoir vos lecteurs.

Recevez avec mes remerciements l'hommage de ma haute et sympathique considération. P. LASSABLIÈRE.

Chef de Laboratoire à la Faculté de Médecine de Paris.
Sept. 17th, 1918.

METHODS OF CONTROL OF FRAGMENTS IN GUNSHOT WOUNDS OF THE JAW.

To the Editor of THE LANCET.

SIR,—May I be allowed to make a few remarks on an interesting article under the above heading that appeared in your issue of Sept. 7th by Major H. P. Pickerill.

I appreciate much that Major Pickerill has written, and was particularly gratified to find him adopting as a routine methods and principles that I and my colleague, Mr. Percival P. Cole, at the King George Hospital, have consistently advocated and practised since the early days of the war. I refer in particular to: (1) The importance he attaches to the control of the posterior fragment; (2) the preservation of comminuted fragment of bone; (3) his condemnation of the needless extraction of teeth in the vicinity of the fracture; and (4) his preference for the immediate as opposed to the gradual reduction of malocclusion.

As regards (1), it is interesting to note that as recently as March, 1918, at a meeting of the Odontological Section of the Royal Society of Medicine, Major Pickerill expressed doubt whether we (Mr. Cole and myself) "can control the posterior fragment at any rate by the methods shown." In view of this pronouncement it is interesting to find that, with the exception of the zygomatic screw method, his procedure of controlling the posterior fragment, when the ascending ramus is fractured above the level of the alveolar border, is identical in principle with the one I have always employed—the impression of the fragment being taken with the upper splint *in situ* and a saddle adapted to the model thus obtained and secured to the upper splint.

(2), (3), and (4) were dealt with by me in a paper read at the same meeting, and published later in the Transactions, reference to which will prove the identity of Major Pickerill's method with those therein advocated.

Major Pickerill in his article refers to "the four-tailed bandage," "screw lever splint," and a "submandibular

[1] THE LANCET, August 24th, 1918 (p. 245).

splint." The four-tailed bandage was discarded by me early in the war as being obsolete, the objections to it being so obvious. In its place was substituted a webbing bandage with soft adaptable chin-piece. Two inches of the webbing which passes vertically upwards from the chin is replaced by garter elastic (double thickness, one inch wide). To each piece of webbing at either end is fitted an independent buckle, so that any desired tension can be obtained. With splint in position this bandage efficiently controls any comminuted fragments, bringing them up in position if displaced and maintaining them there, and is, in my opinion, a much simpler and more comfortable device for achieving this than by the screw lever splint.

This bandage also exerts an inward pressure on the lower border of the horizontal ramus of the mandible, and is more than sufficient to overcome the everting pull that occurs in fractures in region of symphysis, and which Major Pickerill obviates by bolting or wiring. That the simpler method of bandaging and splinting does accomplish this end is proved by results, the percentage of non-union of fractures in this area treated on such lines being negligible. The combination of this bandage with the open bite splint entirely obviates the use of suspensory splints objected to by Major Pickerill. One omission in his article is surprising, and that is that there is no reference whatever to the employment of the open bite splint, the advantages of which are so manifold, simplifying as it does the whole treatment of jaw injuries.

As regards the submandibular splint which Major Pickerill uses in the treatment of edentulous cases, I cannot claim to have had any experience with this type. The intraoral supramandibular splint, secured by circumferential wires, being so simple, so efficient in immobilising fragments, in maintaining function, and the end results so uniformly good that occasion has never arisen to experiment with any other.

At the meeting in March above referred to, Major Pickerill made caustic comments on the method of fixation of circumferential wires as being likely to introduce "the unnecessary element of sepsis." Bearing this criticism in mind, his advocacy of a perforating bolt secured by nuts is piquantly inconsistent.—I am, Sir, yours faithfully,

CHARLES H. BUBB,
Honorary Dental Surgeon, the King George Hospital.

Burlington-gardens, W., Sept. 16th, 1918.

A NASAL DRILL IN THE TREATMENT OF ADENOIDS.

To the Editor of THE LANCET.

SIR,—I have been interested since the year 1910 in the observation of cases of chronic lymphatic stasis which have yielded to the treatment designed by Mrs. E. Handcock. In the earlier cases this was applied to the elimination of waste products in the neighbourhood of arthritic swellings; the same principle of artificial lymphatic circulation in later cases showed that the upper air passages could be cleared by external manipulative treatment in many instances of chronic inflammation.

The letters which you have published on nasal drill will draw attention to this undoubted addition to medical knowledge. I am, Sir, yours faithfully,

Harley-street, W., Sept. 24th, 1918. H. BELLAMY GARDNER.

NASO-PHARYNGEAL INFECTION AT THE ONSET OF CEREBRO-SPINAL FEVER.

To the Editor of THE LANCET.

SIR,—Staff Surgeon Fildes's letter in your issue of Sept. 14th, severely criticising Colonel Gordon's views on cerebro-spinal fever, obviously shows his own view to be that many cases of the disease do not have the meningococci in their throats, and he says at the end: "We came to the same obvious conclusion—namely, that Colonel Gordon's statement was much too sweeping, in fact incorrect. Our work is quite well known to Colonel Gordon."

If, Sir, you will turn to the Medical Research Committee's Special Report Series, No. 17, published on August 2nd this year by Staff Surgeon Fildes and Temporary Surgeon S. L. Baker, R.N., you will see on p. 26, under heading, "The Examination of the Patient's Naso-pharynx for Meningococcus," that after mentioning that Flack had found these organisms in this region in all his cases in the earliest stage, and deduced therefrom that their presence was a valuable diagnostic sign in doubtful cases, these authors proceed:—

"We ourselves are unable to confirm Flack's results as to the constant presence of meningococci in the throat because our swabs were taken on the average nine days after onset, while Flack took his much earlier. Rather less than half our cases showed meningococci in the throat. On general grounds, however, it would appear very probable that meningococci are constantly present in the throat, as stated by Flack; nevertheless, we doubt whether this fact can be taken as being practically diagnostic in certain cases."

It would appear, therefore, that Staff Surgeon Fildes is capable of holding two diametrically opposite views on the same subject at, substantially, the same time.

I am, Sir, yours faithfully,

T. G. M. HINE,
Central C.-S.F. Laboratory, Sept. 19th, 1918. Major, R.A.M.C.

SANDFLY FEVER OR INFLUENZA.

To the Editor of THE LANCET.

SIR,—In your annotation in THE LANCET of Sept. 14th you deal with the problem raised by Professor G. Sampietro of the belief in Italy of the identity of sandfly fever with the so-called "Spanish influenza." On superficial examination sandfly fever certainly does simulate influenza in epidemic prevalence, sudden onset, and general clinical features, and while it is well known that the signs and symptoms of certain epidemic disease may materially differ according as they occur in tropical, subtropical, or temperate regions of the world, yet there can be no doubt in the mind of the careful clinician that we are dealing with two distinct diseases, and not the same clinical disease or one modified by climatic change. In sandfly fever pharyngeal and laryngeal irritation and catarrh are uncommon, and if present are very transitory, while the pulmonary manifestations of influenza are practically never seen. Local lesions produced by the bite of the sandfly on exposed surfaces of the body occur in over 90 per cent. of patients with sandfly fever, and in any epidemic this should suffice to establish a definite diagnosis. Mortality in sandfly fever may be said to be nil.

We have in sandfly fever, therefore, a rarity of catarrhal conditions of the respiratory passages, a negligible mortality rate, and a definite local skin lesion, in contrast with the general pharyngeal, laryngeal, or pulmonary catarrh, definite mortality rate, and absence of skin lesion in influenza. These suffice to distinguish the two diseases, quite apart from any bacteriological investigations or the prevalence of the sandfly in the district affected.—I am, Sir, yours faithfully,

J. LAMBERT,
Sept. 20th, 1918. Temporary Surgeon, R.N.

MANGANESE POISONING.

To the Editor of THE LANCET.

SIR,—In the edition just published of the "Nomenclature of Diseases" the metal manganese for the first time finds a place among the poisons. At least its name does not appear in the editions issued in 1896 and 1906. So long ago as 1894 I certified manganese as the primary cause of a young girl's death. Prior to this I had discovered that manganese fumes were emitted from the chimneys of the blacksmith and the plumber during the process of melting the metals they use. The chimneys of these industries never require sweeping and the metallic fumes, along with the products from the combustion of coal such as benzene and naphthalene, go right out to the air. Just as the Gulf Stream is an oceanic current, these fumes form an atmospheric current and travel, especially in the case of the blacksmith, a considerable distance. They are wafted along by prevailing winds, and, gathering moisture, ultimately form a green deposit on wooden fences and trees and the slates and stonework of houses. The deposit in the case of the blacksmith is a bright green and that of the plumber a darker green. The vegetable part of the deposit under the microscope is seen to consist of cells of a very simple character. I have not seen moss near it.

The opinion I formed at that time was that manganese given by the mouth seemed rather inert, but that when injected subcutaneously or inhaled it became poisonous and was cumulative and the symptoms like lead, zinc, and arsenic poisoning.—I am, Sir, yours faithfully,

JAMES GAIRDNER, M.D., D.P.H.,
Crieff, N.B., Sept. 20th, 1918. M.O.H., Crieff.

The War.

THE CASUALTY LIST.

THE following medical officers appear among the casualties announced since our last issue :—

Killed.

Surg.-Prob. N. C. Ward, R.N.V.R.

Died of Wounds.

Capt. J. C. Forsyth, Canadian A.M.C.

Died.

Major A. Johnston, R.A.M.C., qualified at Glasgow in 1883, and held appointments at Monsall Hospital, Manchester, at Wrexham Infirmary, and at the Victoria Hospital, Burnley. At the time of joining up he was medical officer of the Belvidere Fever Hospital, Glasgow, and deputy medical officer of health for the city. For some time he was in command of the Military Isolation Hospital at Aldershot, and died at Glasgow.

Staff Surg. C. D. Marshall, R.N.V.R., was a student at University College Hospital, London, and qualified in 1890. He held appointments at the Royal London Ophthalmic Hospital, at the Children's Hospital, Chelsea, and at University College Hospital, and prior to joining up was in ophthalmic practice in Harley-street, London. He died at the Colaba War Hospital, Bombay, and at the time of his death was principal medical officer in the Persian Gulf and Mesopotamia.

Wounded.

Capt. A. C. B. Biggs, M.C., R.A.M.C.
Capt. J. R. John, R.A.M.C., attached Sherwood Foresters.
Lieut. W. Q. Wood, R.A.M.C., attached Royal Irish Rifles.
Lieut. D. B. Leitch, R.A.M.C., attached Welsh Regiment.
Capt. G. F. Denyes, Canadian A.M.C.
Capt. A. S. Cockburn, Australian A.M.C.
Capt. G. R. Hamilton, Australian A.M.C.
Capt. A. P. Murphy, Australian A.M.C.
Major W. C. Sawers, Australian A.M.C.
Capt. J. Carrick, R.A.M.C., attached, R.F.A.

Previously reported Missing, now reported Prisoner in German Hands.

Lieut. C. Murray, R.A.M.C.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported :—

Lieut. G. K. Elliott, Royal Welsh Fusiliers, killed in action, elder son of Dr. G. Elliott, of Baschurch, near Shrewsbury.

A. D. Pole, Alberta Regiment, killed in action, youngest son of the late Dr. A. Pole, of Lenzie, near Glasgow.

Second Lieut. E. N. Andrews, The Buffs, died of wounds, youngest son of Dr. E. C. Andrews, of Hampstead, London, N.W.

Second Lieut. C. J. N. Lambert, M.C., R.F.A., killed in action, elder son of Dr. H. L. Lambert, of Barnes, London, S.W.

Capt. G. P. Randall, M.C., King's Own Scottish Borderers, killed in action, eldest son of Dr. P. N. Randall, of Bromley, Kent.

H. P. Clepperton, Queen's Royal West Surrey Regiment, killed in action, son of the late Dr. J. Clepperton, of Broughton, Hants.

Second Lieut. C. E. Hadwen, killed in action, only son of Mr. A. St. J. Hadwen, of Ilford, Essex.

Capt. L. V. Royle, M.C., Royal Air Force, killed whilst flying, elder son of Mr. A. Royle, C.B., of Esher, Surrey.

THE HONOURS LIST.

In recognition of his services on the occasion of the sortie of the *Goeben* and *Breslau* from the Dardanelles on Jan. 20th, 1918, the *Distinguished Service Cross* has been conferred upon—

Surg. James Maurice Harrison, R.N. (H.M. Monitor "M28").

A wounded man having fallen into the water, Surg. Harrison went in after him and kept him afloat until picked up. It was due to his untiring efforts that eight severely wounded cases arrived in good condition at the hospital ship 22 hours later.

For services in action with enemy submarines the *Distinguished Service Cross* has also been conferred upon—

urg.-Prob. G. E. Strahan, R.N.V.R.

The following awards to medical officers are announced. All are members of the R.A.M.C. unless otherwise stated :—

Bar to the Distinguished Service Order.

Capt. (acting Lt.-Col.) WILLIAM BLACKWOOD, D.S.O.—For conspicuous gallantry and devotion to duty while in charge of the evacuation of casualties from the Divisional front during an enemy attack. When communication with the advanced dressing station was cut by enemy barrage he re-established communication and personally visited the posts under his administration. Throughout the fighting he visited the forward area daily, and his indefatigable energy and exceptional organising ability were invaluable to the Division.

Maj. (temp. Lt.-Col.) THOMAS ERNEST HARTY, D.S.O.—For conspicuous gallantry and devotion to duty. For nearly a month this officer was in charge of the evacuations of the wounded on the front of a whole Division. His initiative, courage, and resource during much heavy fighting resulted in the successful clearing of all wounded in the forward area, which he frequently visited during heavy shelling to see that his orders were being executed properly, and also to inspire confidence. He never spared himself in his efforts to arrange for the wounded.

Distinguished Service Order.

Temp. Capt. RALPH FRANKLIN EMINSON.—For conspicuous gallantry and devotion to duty. When two companies who had made a counter-attack and reached a village were obliged to fall back 150 yards, suffering heavy casualties, whom it was impossible to rescue owing to the accurate machine-gun and rifle fire from the village, this officer went himself, regardless of fire, and in full view of the enemy, across "No Man's Land" many times, and carried and assisted back the wounded, who would otherwise have been left.

Major JAMES BEVERLEY METCALFE, M.C., Australian A.M.C.—For conspicuous gallantry and devotion to duty. In a village under heavy bombardment of gas and high explosives, this officer, with practically no protection, tended the wounded for four and a half hours. When the advanced dressing station had been moved to a new site, he remained with four men evacuating odd cases which continued to come in until two shells came right into the dressing-room, severely wounding him. His cheerfulness and coolness throughout encouraged all around him.

Temp. Capt. (acting Major) HENRY MOORE, M.C.—For conspicuous gallantry and devotion to duty. He went through heavy machine-gun and rifle fire to a dressing station which was being evacuated and cleared a large number of wounded. He also took cars to battery positions which were being shelled, and removed the wounded to safety. At the dressing stations during enemy bombardment he remained to the last, and saved many lives by his courage and devotion to duty.

Major LESLIE GEMMEL TASSIE, Australian A.M.C.—For conspicuous gallantry and devotion to duty. This officer set a fine example of coolness in going about amongst his stretcher-bearers directing and encouraging them. Day and night he visited the regimental aid-post and loading-posts, rearranging bearer relays and supervising the evacuation of wounded. Hearing there were several wounded in a village which was being heavily shelled, he organised parties and cleared the village.

Capt. and Bt. Major ARTHUR WALKER.—For conspicuous gallantry and devotion to duty in establishing forward dressing stations and continuing to work in them until forced to move by the immediate proximity of the enemy. He was repeatedly working in the open under heavy fire, no protection being available. He undoubtedly saved many lives which would have been lost but for his courage and initiative.

Second Bar to the Military Cross.

Capt. (acting Major) FRANK GRAHAME LESCHER, M.C.—For conspicuous gallantry and devotion to duty. When his camp was heavily shelled he had the wounded removed and attended them in the open for six hours. Again, during the night, when the transport was bombed, he proceeded to the scene and extricated the wounded men and attended to them, although the enemy continued to shell the position.

Temp. Capt. CLARENCE RANDOLPH YOUNG, M.C.—For conspicuous gallantry and devotion to duty. When all the officers of the battalion had become casualties, and his aid-post was almost surrounded by the enemy, he succeeded in evacuating many of the wounded in spite of continuous and heavy fire. His energy and disregard for his personal safety inspired all who came in contact with him.

Bar to the Military Cross.

Temp. Capt. GEORGE OLIVER FAIRTLOUGH ALLEY, M.C.—For conspicuous gallantry and devotion to duty. After the troops had retired past his aid-post, which was temporarily established in a shell hole, this officer continued to attend to and evacuate the wounded. He was exposed to fire from both sides, but succeeded in regaining the line after having evacuated all the wounded. He thus prevented any of them falling into the hands of the enemy.

Temp. Capt. (acting Major) BERTRAM FRIEND BARTLETT, M.C.—For conspicuous gallantry and devotion to duty as battalion medical officer. Under heavy machine-gun and shell fire he continuously bandaged wounded. Though early in the day wounded, he stuck to his duties, and his pluck and determination saved many lives.

Temp. Capt. STANLEY JAMES ANNEAR BEALE, M.C.—For conspicuous gallantry and devotion to duty in working unceasingly for 48 hours at advanced aid-posts. As each post in its turn became untenable he moved back to another, all the time carrying on dressing and evacuating wounded, while frequently exposed to machine-gun fire. By his energy he was responsible for saving large numbers of wounded from falling into the enemy's hands.

Capt. JOHN ARTHUR BELL, M.C.—For conspicuous gallantry and devotion to duty in action. He was ordered to replace a medical officer who was wounded, and at once went up through a heavy barrage, establishing a dressing station in the open, and showed the greatest coolness and devotion to duty in attending the wounded under very heavy shell fire. He continued his fine work for several days, and was the means of saving many lives. His courage and fine example greatly inspired all ranks with him.

Capt. **HAWTREY WILLIAM BROWNE**, M.C.—For conspicuous gallantry and devotion to duty. When an advanced dressing station was cut off by the enemy barrage this officer made a very plucky attempt to reach it. Later, when, owing to losses amongst battalion M.O.'s, he was sent to a regimental aid-post, he remained there until the enemy was within 300 yards of it, evacuating all his wounded and coming back with the last case under machine-gun fire. He set a fine example of coolness and resource.

Temp. Lieut. (acting Capt.) **WILLIAM KEALTY CAMPBELL**, D.S.O., M.C.—For conspicuous gallantry and devotion to duty during a withdrawal. After a long march he took over the advanced evacuation of the wounded, and having visited the whole line, made his dispositions. Next day he visited all R.M.O.'s under machine-gun fire. He showed great energy and determination.

Capt. **HARRY EDMUND CRESWELL**, M.C.—For conspicuous gallantry and devotion to duty. After an intense bombardment with gas shells a village was ordered to be cleared. He was one of the last to leave, and, though he himself was very badly gassed, he continued to work until he had done everything for the casualties that lay in his power, and was ordered to the field ambulance.

Temp. Capt. **JOHN POLSON DAVIDSON**, M.C.—For conspicuous gallantry and devotion to duty while in charge of forward bearers. By his cool courage he was largely instrumental in getting away all wounded under heavy shell fire. His consistent devotion to duty set a splendid example to all his party,

Capt. **THOMAS McNAUGHTON DAVIE**, M.C.—For conspicuous gallantry and devotion to duty. When battalion headquarters were practically surrounded, and he saw that he could be of no further use, he made his escape, and after all the officers of the battalion had become casualties, he remained with the men in the open throughout the fighting on that and the following day. The next day he again went into action with the remnants of the battalion in a counter-attack, rendering excellent service. His cool self-possession and devotion to the wounded under very heavy fire did much to steady all ranks.

Capt. (acting Major) **FRED ELLIS**, M.C.—For conspicuous gallantry and devotion to duty during an enemy attack. When the enemy had approached within 200 yards of his advanced dressing station he ordered his personnel to withdraw, and remained at his post under heavy shell fire with a few men to care for the wounded. When a bridge over which the cases were evacuated was destroyed, he evacuated by hand-carry to a point a mile distant, and he managed to salve his two ambulance cars. His services were of a high order.

Temp. Capt. **JOHN JAMES HARROWER FERGUSON**, M.C.—For conspicuous gallantry and devotion to duty. He went forward in charge of bearer squads, under machine-gun fire, to find a regimental aid-post with which contact had been lost. When there he showed great disregard for personal safety, and set a fine example to the bearers, and did not leave the post until all the casualties had been evacuated, although the enemy was almost in the immediate vicinity.

Capt. **FRANK PERCY FREEMAN**, M.C.—For conspicuous gallantry and devotion to duty during an enemy attack. Though wounded by a shell, he first attended to others wounded by the same shell. Later he accompanied his commanding officer through a heavy barrage of high explosives and machine-gun fire to the corps line, where he stayed for two hours attending to wounded.

Temp. Capt. (acting Major) **HUGH BERNARD GERMAN**, M.C.—For conspicuous gallantry and devotion to duty while in charge of stretcher-bearers. He supervised the evacuation of wounded from the front line to the advanced dressing station, often under heavy shell fire. Also he continuously dressed wounded in a dressing station unprotected from shell fire.

Temp. Capt. (acting Major) **ROBERT MASSON GREIG**, M.C.—For conspicuous gallantry and devotion to duty throughout prolonged fighting. For about a fortnight he worked with but little sleep and food, collecting and carrying in wounded under intense shell and machine-gun fire. During this period he maintained touch with six different battalions, and successfully got away all their wounded.

Temp. Capt. **AUSTIN HARVEY HUYCKE**, M.C.—For conspicuous gallantry and devotion to duty. When the officer in charge of an advanced dressing station and several of his orderlies were killed or wounded, he went forward and took charge of the station, and by his courage and energy under heavy shell fire succeeded in getting away the cases. He saved many lives.

Temp. Capt. **EDMUND BASIL JARDINE**, M.C.—For conspicuous gallantry and devotion to duty. Though his dressing-station was blown up by shell fire, and when transferred to another place was again shelled, he steadily continued his work. He gallantly made several journeys to the regimental aid-post under extremely heavy fire, and located and disposed of all casualties collected there. His zeal, courage, and untiring energy were beyond all praise.

Temp. Capt. **JAMES HUNTLY LEGGE**, M.C.—For conspicuous gallantry and devotion to duty when acting as bearer officer during a raid. He established a post in the front line, which came under continuous and heavy barrage. Hearing there were wounded in front he several times led squads of bearers through the barrage and brought in wounded. It was largely due to his magnificent efforts that the clearing was successfully accomplished, and only two men were missing. His energy and devotion to duty were the means of saving many lives.

Temp. Capt. **GEORGE EDWIN LINDSAY**, M.C.—For conspicuous gallantry and devotion to duty. Not only did this officer carry out his professional duties with a cheerfulness that inspired all ranks, but on two occasions, regardless of personal danger, he continually attended wounded in the open under heavy machine-gun and rifle fire, only withdrawing when ordered to by his C.O.

Capt. **JOHN WRIGHT MALCOLM**, M.C.—For conspicuous gallantry and devotion to duty during an enemy attack. He was at an advanced dressing station with another medical officer, and seeing the enemy advancing they loaded their car with wounded and, picking up others on the way, conveyed them to a safe place. During the journey he was under close and constant fire.

Temp. Capt. **FREDERICK BUICK McCARTER**, M.C.—For conspicuous gallantry and devotion to duty. During a severe engagement this officer established an advanced dressing station within 200 yards of the front line, where for 48 hours, continuously under heavy fire, he attended to the casualties and arranged for their evacuation.

Capt. **WILLIAM HILGROVE LESLIE McCARTHY**, M.C.—For conspicuous gallantry and devotion to duty. This officer, hearing that an aid-post was filled with wounded who could not be evacuated by the normal route owing to the enemy bombardment, led a party of stretcher-bearers through heavy shell fire and reorganised the evacuation. He dressed four wounded men in the open on the way up, and made several journeys during the day.

Temp. Capt. **DANIEL McKELVEY**, M.C.—For conspicuous gallantry and devotion to duty in evacuating the wounded. With a small ambulance car he went to and fro right up to the firing line, meeting the stretcher-bearers and bringing back the wounded as soon as dressed. In spite of heavy fire he carried on his well-organised arrangements. Later, whilst looking for a new dressing station, he was captured, but managed to make good his escape. Throughout the operations he displayed great energy, and his work was magnificent.

Temp. Capt. **GEORGE BOYD McTAVISH**, M.C.—For conspicuous gallantry and devotion to duty. Throughout nine days' operations he worked continuously in charge of the bearer division, and refused to be relieved. He went to and fro superintending the clearing of the wounded, quite regardless of the many barrages he had to pass, and no doubt saved many lives by his untiring zeal and coolness.

Capt. **DUNCAN WESTLAKE PAILTHORPE**, M.C.—For conspicuous gallantry and devotion to duty after a raid in collecting wounded under fire, working till daylight. He then went out in broad daylight, established the fact that a man reported missing was dead on the enemy's wire, and brought him in from within ten yards of the wire.

Temp. Capt. **REGINALD THOMPSON RAINE**, M.C.—For conspicuous gallantry and devotion to duty. He attended the wounded under heavy rifle and shell fire, and superintended their evacuation. By his devotion to duty he set a fine example to all ranks.

Capt. **JOHN ELVIN RUSBY**, M.C.—For conspicuous gallantry and devotion to duty. During an intense bombardment an artillery dug-out was blown in. This officer with his stretcher-bearers dug out two officers and three men who were buried. Later he went to an exposed flank to attend to wounded men under heavy fire. Throughout the whole week's operations he worked untiringly, and undoubtedly saved many lives.

Capt. (acting Major) **ARTHUR ASHTON SMALLEY**, M.C.—For conspicuous gallantry and devotion to duty in his skilful and bold leading of the stretcher-bearers and in evacuating the wounded. By his devotion to duty under the heaviest fire he was always an inspiring example to his men.

Capt. (acting Major) **CHARLES NIXON SMITH**, M.C.—For conspicuous gallantry and devotion to duty. This officer was in charge of an advanced dressing station and the collection of wounded from two infantry brigades for four days. By reconnoitring and frequent visits to his posts he was able to keep in touch with the rear aid-posts, and to vary his arrangements according to the casualties. He administered the advanced dressing station in a building with little protection, which was repeatedly hit by shells. His scheme for evacuating the wounded worked well, and a large number of casualties were quickly got away.

Temp. Capt. **JAMES WILLIAMSON TOCHER**, M.C.—For conspicuous gallantry and devotion to duty. On several occasions he showed great organising skill under very trying conditions. During the attack of a brigade he worked at and between two posts, and succeeded in evacuating all the wounded. His coolness and devotion to duty throughout were a splendid example to the officers and men working under him.

Capt. **WILLIAM JOSEPH WEBSTER**, M.C.—For conspicuous gallantry and devotion to duty when getting up to a collecting-post and supervising the evacuation of the wounded under direct enemy machine-gun fire. His ambulance car had most of its body blown away and the radiator perforated. In spite of this by plugging the holes with candle grease, he was able to bring the car back through the heavy barrage with eight wounded men. He showed fine devotion to duty.

The Military Cross.

Lieut. **JOSEPH ADAMS**.—For conspicuous gallantry and devotion to duty in dressing and attending to wounded in an aid-post under heavy shell fire, and later in organising stretcher parties and getting wounded away under heavy fire.

Temp. Capt. **DOUGLAS REID ALEXANDER**.—For conspicuous gallantry and devotion to duty in constantly attending to wounded under heavy shell fire, working day and night for six days at very high pressure. He showed a fine example of coolness and courage to all, and by his perseverance the lives of many were saved.

Capt. **FRANCIS DIGHTON ANNESLEY**.—For conspicuous gallantry and devotion to duty in action. When a report was brought to headquarters of a brigade that the cookhouse of the battery had been struck, and that there were many killed and wounded men inside, he immediately left his aid-post and went forward to see what assistance he could give. Whilst going up, a shell struck the remaining portion of the cookhouse, partially burying the occupants. He personally assisted in extricating the men, dressed their wounds on the spot under heavy shell fire, and got them away safely to the dressing station. His promptness and courage were undoubtedly the means of saving several lives.

Capt. **GEOFFREY PENROSE ARNOLD**, Australian A.M.C.—For conspicuous gallantry and devotion to duty. During a night counter-attack this officer formed his regimental aid-post in the open just in front of the jumping-off line, and continued to dress wounded there for twenty-four hours under continuous fire. The medical officers of two other battalions both became casualties early in the attack, and he attended to the wounded of these battalions besides his own. His coolness and splendid work saved scores of lives.

Capt. **FREDERICK STANLEY BEDALE**.—For conspicuous gallantry and devotion to duty. This officer was working at an aid-post in a village, a portion of which was captured by the enemy. He remained until the last possible moment, only leaving when all wounded had been evacuated. He then established an aid-post in the open, working unceasingly day and night, being the only medical officer left in the area, and his staff greatly reduced. His attention to the wounded, at great personal risk, was most praiseworthy.

Capt. **FRANCIS LIONEL PERCY GARNETT BENNETT**.—For conspicuous gallantry and devotion to duty. Seeing that wounded men were in danger of becoming prisoners, he obtained ambulance cars, and three times personally took them away under heavy shell and machine-gun fire. On the last occasion he was himself wounded, but he sent his last car away full and struggled on on foot until he met with assistance. He had been working continuously for 48 hours previously.

Temp. Lieut. (temp. Capt.) JOHN HAMILTON BOAG.—For conspicuous gallantry and devotion to duty. When his aid-post was occupied by the enemy he hastily established himself in a new position and rendered valuable assistance. He several times went fearlessly out under machine-gun fire and brought in casualties, and by his devotion saved many lives.

Temp. Capt. (acting Major) CECIL ANDERSON BOYD.—For conspicuous gallantry and devotion to duty. He repeatedly attended to wounded under heavy shell fire, and on several occasions was compelled to evacuate his aid-post, succeeding each time in removing all his wounded, often across country, and by his fine judgment and tireless energy saving a large number from falling into the enemy's hands. His conduct throughout was excellent, the conditions being exceptionally hazardous and trying.

Temp. Capt. HAROLD FRANCIS BRICE-SMITH.—For conspicuous gallantry and devotion to duty. This officer displayed great gallantry during ten days' severe fighting, attending to wounded men under severe hostile artillery fire. He was himself wounded in the arm at an early stage, but with unselfish devotion he remained at his duty throughout the operation, rendering most valuable service night and day, although suffering great pain from his injuries.

Capt. (acting Major) GEORGE ALLMAN BRIDGE.—For conspicuous gallantry and devotion to duty. This officer, who was in charge of a forward dressing station and bearer posts, hearing that one had been blown in, proceeded at once with a N.C.O. through a heavy barrage and rescued the injured men, conveying them to a place of safety. After establishing another post he filled up shell holes at a cross road to enable motor ambulances to pass.

Capt. (acting Major) CHARLES FRANK BURTON.—For conspicuous gallantry and devotion to duty in his skilful leading of the stretcher-bearers on all occasions. He has always shown great coolness under the heaviest fire.

Capt. CHARLES HOPE CARLTON.—For conspicuous gallantry and devotion to duty. He took an ambulance car into a village after the enemy had entered it, and succeeded in clearing several wounded in the face of heavy machine-gun and rifle fire. Throughout operations he showed great energy and devotion to duty under very difficult conditions.

Temp. Capt. (acting Major) PHILIP CARNEY.—For conspicuous gallantry and devotion to duty in leading motor ambulance wagons up to a village under heavy fire and bringing away the last of the wounded. On many occasions he showed a splendid example of devotion to duty under most difficult conditions.

Capt. GERALD FRANCIS CARR.—For conspicuous gallantry and devotion to duty. Although the advanced dressing station of which he was in charge was shelled out three times, by his coolness and example he got all the patients and personnel safely away, and re-established his dressing station without interrupting the evacuation.

Temp. Capt. CLIFFORD CUTHBERT CHANCE.—For conspicuous gallantry and devotion to duty. When a heavy barrage interrupted communications between regimental aid-posts and relay posts he reorganised his squads and led them through the barrage, cleared all the wounded, and re-established the chain of evacuation. He has repeatedly led his squads through heavy fire and gas shells, and has by his magnificent example of devotion to duty maintained the morale of tired and shaken bearers.

Temp. Lieut. CHARLES CLYNE.—For conspicuous gallantry and devotion to duty. He worked for 24 hours in a barn under machine-gun and shell fire, and evacuated over 200 cases. Two days later, under heavy shell fire, he continued to evacuate wounded. His devotion to duty saved many lives.

Temp. Lieut. GEORGE CARTER COSSAR.—For conspicuous gallantry and devotion to duty. This officer, who was medical officer of the battalion, performed his duties with the greatest coolness under heavy fire and gas shelling for four days, attending to the casualties with great devotion to duty, although on one occasion he became unconscious from gas. He was twice wounded, but remained at his work, though suffering all the time from the effects of gas. His gallant conduct and disregard for his own safety set the finest example to his men and maintained the steadfastness of the workers in the regimental aid-post during many dangerous periods.

Temp. Capt. DOUGLAS CRELLIN.—For conspicuous gallantry and devotion to duty in remaining at an advanced dressing station till all the wounded were clear, in spite of the enemy's approach, and the rain of gas and high explosive shells.

Capt. SPENCER STAWELL CROSSE.—For conspicuous gallantry and devotion to duty in tending wounded under heavy fire. Thanks to his untiring efforts, no wounded were left in the enemy's hands.

Capt. (acting Major) JOHN WILLIAM DALE.—For conspicuous gallantry and devotion to duty. He collected and evacuated many wounded from close up to the enemy lines. Also, he completed evacuation of all wounded from an advanced dressing station when the enemy was within 200 yards. He showed fine courage and determination.

Temp. Lieut. DAVID DAVIES.—For conspicuous gallantry and devotion to duty in organising bearers and attending to the wounded. He took forward the stretcher-bearers in a counter-attack under heavy shell and machine-gun fire to within a few yards of the enemy and collected all wounded.

Temp. Capt. (acting Major) JOHN EDGAR DAVIES.—For conspicuous gallantry and devotion to duty while in charge of stretcher-bearers. He evacuated wounded over ground heavily shelled in full view of the enemy. Although several of his bearers were wounded, he showed a personal disregard for his own safety, and set a fine example to his men.

Capt. ERNEST NOEL BROUGHAM DOCKER, Australian A.M.C.—For conspicuous gallantry and devotion to duty during an attack. He followed up with his bearers, picked up guides, gained touch with the regimental aid-posts, and organised a line of bearer relays. This was done at night under machine-gun and heavy shell fire.

Capt. DONALD GORDON DUFF.—For conspicuous gallantry and devotion to duty. He proceeded to an area that was being heavily shelled, and at once organised stretcher parties, superintended the conveyance of wounded to his dug-out, and returned to make certain that no casualties were left. His coolness and devotion to duty throughout have been most marked.

Temp. Capt. GEORGE DUNLUCE ECCLES.—For conspicuous gallantry and devotion to duty in evacuating his wounded from the firing line. Although obliged to retire on four separate occasions, he with great skill and resourcefulness cleared all his wounded safely. His complete disregard of danger was entirely responsible for a completely successful evacuation under circumstances of considerable difficulty.

Capt. (acting Major) THOMAS STOKOE ELLIOT.—For conspicuous gallantry and devotion to duty. This officer was unremitting in superintending the dressing of the wounded during four days' fighting. He was in charge of three advanced dressing stations, each of which was in turn destroyed by enemy shell fire, but he managed to evacuate all the wounded. Officers, personnel, and patients were all encouraged by his cool example.

Capt. FRANK WILLIAM FAY, Australian A.M.C.—For conspicuous gallantry and devotion to duty while in charge of the transport and evacuation of wounded from the divisional main dressing station. The station was twice hit by shells, but he succeeded in clearing all wounded, exposing himself in bringing up ambulance cars and showing great energy and devotion to duty.

Temp. Capt. JOHN JAMES HARROWER FERGUSON.—For conspicuous gallantry and devotion to duty. When a brother officer was buried amongst a mass of bricks as a result of a shell having struck his billet, this officer, hearing his cries for help, discovered his whereabouts in the darkness, and after four hours' work, although the place was being heavily shelled the whole time, succeeded in extricating him.
